Alkylated polyisopropylhalobenzenes. Robert R. Dreisbach and Geo. B. Heusted (to Dow Chemical Co.). U. S. 2,183,552, Dec. 19. Solvent and dielec. compds. some of which are suitable for use in gasoline contg. Et_4Pb to increase its octane rating are prepd. by treating a benzenoid hydrocarbon or a halogenated deriv. contg. not more than 2 halogen atoms per mol. with propylene, etc., and details are given or mention is made of the production of: triisopropyltoluene, triisopropylxylene, triisopropylethyl benzene, triisopropyl diethyl benzene, tetraisopropyltoluene, triisopropylchlorotoluene, triisopropylbromotoluene, and a liquid mixt. of monomethyltriisopropylchlorobenzenes b_{755} about 283°.

Amino compounds of the anthraquinone series. Geoffrey Lord and George Reeves (to Celanese Corp. of America). U. S. 2,183,652, Dec. 19. A process for the manuf. of amino and aliphatically substituted amino derivs. of anthraquinone comprises the reaction with NH_3 or an aliphatic amine, in the presence of a salt, oxide or hydroxide of Mn or Cu, and in a reaction medium which consists apart from the reactants substantially entirely of a 0.5 to 5% aq. soln. of caustic alkali, an anthraquinone compd. which is at least slightly sol. in such a soln. of caustic alkali and which contains in one of the 1- and 4-positions a substituent hydroxy radical and in the other of such positions a hydroxy, amino or substituted amino radical, so as to replace a hydroxy radical by a residue of the agent employed, the proportion of the metal compd. present being 0.1 to 5% of the wt. of the anthraquinone compd. treated. The process is suitable for use with such compds. as quinizarin, 1,4,5-trihydroxyanthraquinone, 1,4,5,8-tetrahydroxyanthraquinone, 1-amino-4,5,8-trihydroxyanthraquinone, 1-hydroxy-4-aminoanthraquinone and 1-hydroxy-4-methylaminoanthraquinone. Various examples with details are given, involving the use of $CuSO_4$ and Mn chloride.

Selenylarylene thiazoles. Lawrence R. Sperberg (to Wingfoot Corp.). U. S. 2,184,170, Dec. 19. 2-Selenylarylenethiazoles such as 2-selenylbenzothiazole are prepd. by treating a selenide such as that of Na with a 2-halo-substituted arylenethiazole such as 2-chlorobenzothiazole (suitably with heating to 98°).

Compounds of the perhydrocyclopentanophenanthrene series. Max Bockmühl, Gustav Ehrhart, Heinrich Ruschig and Walter Aumuller (to Winthrop Chemical Co.). U. S. 2,183,851, Dec. 19. In prepg. a compd. of the perhydrocyclopentanophenanthrene series such as 3-oxoternorcholenylamine, an Al alcoholate such as (*tert*-Bu)Al is caused to react, in the presence of a ketone such as acetone, upon a compd. of the polyhydrocyclopentanophenanthrene series substituted in the 3-position by the hydroxyl group and in the 17-position by a basic group, such as 3-hydroxyternorcholenylamine.

Dimethylpolyhydroketocyclopentanophenanthrols. Friedrich Hildebrandt (to Schering Corp.). U. S. 2,184,299, Dec. 26. A method for producing dimethylpolyhydrocyclopentanophenanthrene compds. of the general formula $C_{19}H_n(x)(y)$, where n is an odd number from 27 to 29 inclusive, y represents a member of the group of substituents consisting of the hydroxyl group and groups which on hydrolysis are transformed into the hydroxyl group, and x is a member of the group consisting of the keto group =O and the secondary alc. group (OH)H the compn. of the compds. corresponding to the structural formula

(I)

the dotted line in the formula indicating the probable position of the double bond in the case of the unsatd. compds., comprises the reaction of pregnanolones of the general formula $C_{21}H_mO_2$, where m is 34 in the case of the satd. and 32 in the case of the unsatd. compds., and corresponding to the structural formula I with x = CH_3CO and y = OH, with an organometallic compd. of the Grignard type, splitting off water between the tertiary hydroxy group and the neighboring H atom of the secondary-tertiary dialc. obtained, thereby leaving a double bond in the side chain, oxidizing the unsatd. alc. obtained to split the mol. at the point of such double bond, and isolating the reaction product.

Reaction of alkali metals with aromatic hydrocarbons. Norman D. Scott (to E. I. du Pont de Nemours & Co.). U. S. 2,183,847, Dec. 19. A method of effecting the addn. of an alkali metal to a polycyclic aromatic hydrocarbon which will form addn. compds. therewith, the hydrocarbon being from the group consisting of anthracene, binaphthyl, acenaphthene, retene and their homologs, comprises causing the alkali metal and the hydrocarbon to react in a reaction medium which contains in sufficient amt. to promote the reaction a polyether from the group consisting of glycol formal, methylglycerol formal, and dimethylenepentaerythritol.

Alkaline earth salts of inositol tetraphosphate. Franz Fischler. Ger. 684,946, Dec. 8, 1939 (Cl. 12*o*. 25). The ext. obtained by lixiviation of bran with hot, dil. acids is filtered; the filtrate is treated with 8-fold the amt. of Na_2-

HPO_4 calcd. upon the dissolved inositol, and with an alk. earth salt; the reaction is adjusted to pH 5.0–5.4 by alkali hydroxide soln.; the ppt. resulting upon heating to 90° after addn. of a concd. acetate soln. is dissolved in hot 5% HCl. The pptn. of the inositol phosphate is repeated under the same conditions and subsequently the soln. prepd. by treatment of the ppt. with 5% HCl adjusted to a pH value that depends on the alk. earth tetraphosphate desired. From this soln. the alk. earth inositol tetraphosphate is pptd. by means of an alk. earth salt.

Vinyl halides. Karl Jung (to I. G. Farbenind. A.-G.). U. S. 2,183,240, Dec. 12. In the manuf. of a vinyl halide by the addn. of a H halide to C_2H_2 in the presence of a mercuric halide, the reaction is effected in the presence of glycol or other org. solvent of low mol. wt. selected from the polyhydric aliphatic alcs. or their halohydrins in which the mercuric halide is dissolved.

Alkene sulfides. Willem Coltof (to Shell Development Co.). U. S. 2,183,860, Dec. 19. A process for the dehydrochlorination of 1-chloroethane-2-thiol to ethylene sulfide while avoiding the substantial formation of ethylene sulfide polymers comprises treating the 1-chloroethane-2-thiol with an alkali metal bicarbonate in an aq. medium, the alkali metal bicarbonate being used in sufficient amt. to combine with the liberated HCl and maintain the pH of the reaction mixt. in the range of from 7.5 to 9.5. Similarly, other haloalkanethiols also may be treated.

Pure salts of acid esters of polybasic inorganic acids. N. V. de Bataafsche Petroleum Maatschappij (A. J. Tulleners, inventor). Dutch 47,009, Nov. 15, 1939. Alkali alkyl sulfates obtained by absorption of alkenes in sulfuric acid and neutralization are usually contaminated with alkali sulfate. Purification is effected by alcohols of 6 or more C atoms, 2-heptanol, benzyl alc., terpineol, etc., which dissolve the alkali alkyl sulfate. The extn. is preferably effected on the moist reaction product or soln. and can be continuous. The solvent is recovered by steam distn. A temp. of 100° is preferred during the extn. to promote sepn. of the mixt. into phases.

Aliphatic acid. Wm. O. Kenyon (to Eastman Kodak Co.). U. S. 2,184,555, Dec. 26. An aq. alc., such as EtOH for the production of HOAc, is caused to react with at least a molar proportion of water in the presence of a Cu-Zn-Mn alloy catalyst, at about 290–350°, and similar conversions may be effected with use of AcH or PrOH, etc., as initial material.

Unsaturated acids from aldehydes. Hanns P. Staudinger (to Distillers Co. Ltd.). U. S. 2,183,325, Dec. 12. An aldehyde, such as crotonaldehyde for the production of crotonic acid, is subjected to the action of O in the presence of a per compd. of an org. acid which is completely miscible with the aldehyde, such as peracetic acid (suitably at room temp.).

Concentrating acetic acid. Donald F. Othmer (to Eastman Kodak Co.). U. S. 2,184,563, Dec. 26. An arrangement of app. is described, and a process of concg. aq. HOAc which involves mixing with it not more than the right amt. of heptane or dioxane to form an azeotropic mixt. with the water present and distg. water together with the added treating agent.

2,4 - Dioxo - 3,3 - dialkyltetrahydropyridine - 6 - carboxylic acids. Otto Schnider (to Hoffmann-La Roche Inc.). U. S. 2,170,781, Aug. 22. See Ger. 668,489 (*C. A.* **33**, 2150⁴).

Purifying acetylene and producing acetaldehyde from it. Eger V. Murphree (to Standard Oil Development Co.). U. S. 2,183,148, Dec. 12. An arrangement of app. is described, and a process of making AcH from acetylene which involves bringing a gaseous mixt., contg. a substantial amt. of acetylene and a small amt. of impurities of the nature of diacetylene and gases inert in the aldehyde conversion process, with a solvent, at a temp. low enough, under the pressure conditions used, to effect soln. in the solvent of at least a major proportion of the impurities but high enough to effect soln. of not more than a relatively small proportion of the acetylene, passing the purified gases to a conversion zone to produce AcH and recycling the residual gases from the aldehyde conversion process to a stripping zone to remove dissolved gases from the charged solvent. Gas, oil, acetone or toluene may be used as the solvent.

Methyl methacrylate and related compounds. Patrick D. Ritchie, David T. Jones and Robert Burns (to Imperial Chemical Industries Ltd.). U. S. 2,183,357, Dec. 12. In producing Me methacrylate, Me α-hydroxyisobutyrate is acetylated to Me α-acetoxyisobutyrate, and the product is subsequently pyrolyzed at 400–600°. Likewise, various other lower alkyl esters or nitriles of α,β-unsatd. monocarboxylic aliphatic acids are produced by subjecting in the vapor form to temps. considerably in excess of their b. ps., esters, nitriles or amides of mono- or di-alkylglycolic acids in which the H atom of the α-hydroxyl group (i. e., alcoholic) has been replaced by the acidic radical of an acid which is volatile, or of which the decompn. products are volatile, at the temp., the substituted glycolic acids may be illustrated by the formula $RR_1C(OX)CO_2H$, where R is an alkyl radical, R_1 is H or an alkyl radical and X is an acyl radical of an acid which is volatile at the temp. of the reaction. In carrying out the process, atm. pressures may be used. The optimum temp. for the reaction varies somewhat according to the particular deriv. undergoing decompn.; but in general it is preferred to employ temps. between about 400 and 600°. The heat treatment is conveniently carried out by passing the vapor of the substance through a heated tube, if desired together with an inert diluent gas or vapor such as N or CO_2. The tube may be suitably packed, for example with quartz, to increase the heating surface, and catalytic packing materials such as silica gel or graphite may also be used. Numerous examples with details are given.

Chlorinating cyclohexane. Arthur A. Levine and Oliver W. Cass (to E. I. du Pont de Nemours & Co.). U. S. 2,183,574, Dec. 19. In order to produce cyclohexene, cyclohexane is caused to react with an amt. of Cl only sufficient to convert a minor proportion of the cyclohexane to monochlorocyclohexane, and the resulting mixt. is passed over a dehydrogenchlorination catalyst such as charcoal impregnated with $BaCl_2$ at a temp. of 400–500°. Cf. *C. A.* **33**, 5411⁶.

Isophorone. Thomas H. Vaughn and Donald R. Jackson (to Union Carbide and Carbon Research Laboratories, Inc.). U. S. 2,183,127, Dec. 12. Acetone vapors are brought into contact with a catalyst comprising CaO, $Ca(OH)_2$ or CaC_2 (suitably at a temp. of about 350°) and isophorone is isolated from the resulting vaporous reaction products (as by condensation and fractional distn. under superatm. pressure).

Mono-, di- and tri-nitrotoluenes. P. A. F. de Beule. Belg. 430,040, Oct. 31, 1938. Toluene is nitrated at −25° to +25° in a soln. contg. at all times above 85% HNO_3.

Butadiene production from 1,3-butylene glycol. Martin Müller-Cunradi and Heinz Krekeler (to I. G. Farbenind. A.-G.). U. S. 2,184,164, Dec. 19. App. is described, and a process which involves heating 1,3-butylene glycol in a still in the liquid phase in the presence of sulfonic acids of aromatic hydrocarbons, distg. off the reaction products formed including butadiene, water and intermediate products of the dehydration of 1,3-butylene glycol, cooling the distillate to sep. the butadiene from the water and intermediate products, sepg. the intermediate products from the water, and returning them to the still so that they enter into fractionating exchange with the reaction products distg. off.

1-Alkyl-1-aryl-1,3-butadiene. Erich Lehmann. Ger. 684,797, Dec. 5, 1939 (Cl. 12*o*. 19.01). 1-Alkyl-1-aryl-1-halo-3-butene is permitted to drop at a rate of 1–2 drops per sec. upon alk. earth under 40–60 mm. pressure at 220–60°.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

ARTHUR W. DOX

The specificity of sulfopeptidases. I. The adsorptive distribution of kidney peptidase. Tunehiro Kazama. *Acta Schol. Med. Univ. Imp. Kioto* **23**, 154-9(1939).—Kidney exts. contg. carboxypeptidases were shaken with alumina Cγ (120 cc. dild. with equal vol. of acetate buffer pH 5.1, plus 16 cc. of a suspension of alumina contg. 149.1 mg. Al_2O_3). The adsorbate was washed 3 times with H_2O and treated for 20–30 min. with 120 cc. of 0.04 *N* NH_4OH contg. 17% glycerol. The supernatant fluid split β-naphthylsulfonyldiglycine (I) 63%; benzoyldiglycine (II) 21.5%; and benzoylglycine (III) 15%. The adsorbate dried with filter paper and neutralized with 0.2 *N* HCl split I 19.7%, II 9.6% and III 81%. On further adsorption and elution, the eluate contained no enzyme; the adsorbate split II 6%, III 78% and did not split I. II. **Influence of acyl groups of substrate on the activity of carboxypeptidase.** *Ibid.* 160–8.—Exts. of pancreas contg. carboxypeptidase were subjected to adsorption and elution, the adsorbents being alumina Cγ, Fe_3O_4, kaolin, kieselguhr and acid clay "Adsol." It was possible to obtain a fraction which hydrolyzed benzoylglycine and *l*-leucine but not β-naphthylsulfonylglycyl-*l*-leucine or chloroacetyl-*l*-phenylalanine. E. S. G. Barron

Action of enzymes on polypeptides containing acyl derivatives of glycine. Tunehiro Kazama. *Acta Schol. Med. Univ. Imp. Kioto* **23**, 169-75(1939).—Numerous acyl derivs of polypeptides were prepd. with glycine exclusively: diglycine (I), triglycine (II), β-naphthylsulfonyldiglycine (III), β-naphthylsulfonyltriglycine (IV), benzoylglycine (V), benzoyldiglycine (VI), benzoyltriglycine (VII), chloroacetyldiglycine (VIII), chloroacetyltriglycine (IX). Polypeptidase prepd. from pig tissue (dry powder dehydrated with acetone and ether, extd. for 3 hrs. at 37° with 10 vols. of 87% glycerol, centrifuged, filtered, and dild. with H_2O, 1:4) was used for the hydrolysis. A titration value corresponding to 1.67 cc. of 0.2 *N* KOH was taken as 100%. With kidney ext. at pH 7.8 to 8.0 and 37°, I was split 67% in 60 min.; II, 21% in 67 min.; III, 37% in 48 min.; IV, 11% in 37 min.; V, 85% in 48 min.; VI, 8% in 85 min.; VII, 107% in 24 min.; VIII, 33% in 48 min. With pancreas ext. I was split 100%, II 62%, IV 75% and VI 39%, each in 24 min.; V 5% and VIII 1% in 48 min.; while III, VII and IX were not split. With intestinal ext. I was split 35% in 90 min.; II 38%, V 1%, VII 37% and VIII 3% in 48 min.; while III, IV and VI were not split. *Ibid.* 176-80.—Glycerol exts. of liver and spleen contg. carboxypolypeptidase were treated with 20% AcOH (to 220 cc. of ext., 1.6 cc. of AcOH) for 4 hrs. at 37°, and were incubated with the polypeptides at pH 4.2, 37°. Liver ext. hydrolyzed only the Bz derivs. Papain activated with HCN had no action on these polypeptides. E. S. G. Barron

Production of alcohol in cadavers. Folco Domenici. *Arch. ist. biochim. ital.* **11**, 161-204(1939); cf. *C. A.* **33**, 6515.—Dead rabbits left for 73 hrs. to 30 days at 0.4° to 19° formed volatile substances previous distns. of which gave, on titration with dichromate, amts. corresponding to 0.07 to 1.28 g. of alc. %. When the animals were buried 1 m. deep at 13° to 17° the amt. found was from 0.05 to 0.28 g. %. The amt. diminished when the thorax was left closed. E. S. G. Barron

Microscopic method of electrophoresis and its application to the study of ionogenic and nonionogenic surfaces. Harold A. Abramson. *Trans. Faraday Soc.* **36**, 5-15 (1940).—Optically flat electrophoresis cells alone are capable of giving sufficient precision (3 to 10% error) to give results comparable with those obtained in U-tubes. Some data are reviewed on proteins like horse serum albumin and egg albumin adsorbed on quartz and collodion particles and on amino acid crystals. Titration curves and elec. mobility of serum albumin and pseudoglobulin show that from pH 4 to 8 the elec. mobilities are proportional to the combining power of the proteins with H^+ and OH^- ions. Victor R. Dietz

Influence of electrolyte concentration on the electrophoretic mobility of egg albumin. Arne Tiselius and Harry Svensson. *Trans. Faraday Soc.* **36**, 16-22(1940).—The mobility of egg albumin at +0.5° in phosphate buffer of pH 7.10 and of varying ionic strength (0.20 to 0.0014) was detd. by the moving boundary method. As a limiting case at very low concns., the protein migrates as a free ion. The reduction in mobility caused by increasing ionic strengths, can be accounted for by the Debye-Hückel-Henry theory of electrophoresis. Some measurements were made in the isoelec. region (pH = 4.4–4.8) and at ionic strengths 0.10, 0.05, 0.02, 0.01 (acetate buffers) at 0.5°. The displacement of the isoelec. point by variation of the ionic strength may be explained partially by the combination of other ions than H^+ and OH^- with the protein. Victor R. Dietz

Membrane potentials, valences and theoretical and observed mobilities of hemoglobin and egg albumin. G. S. Adair and M. E. Adair. *Trans. Faraday Soc.* **36**, 23-32 (1940). Thrice-recrystd. egg albumin and CO-hemoglobin in the same activities of electrolytes (Na phosphate buffer mixts.) have been used both for the thermodynamic detns. of potential and charges and for electrokinetic measurements. The values of pH were between 6.8 and 7.6. The collodion membrane potentials, the valences and the excess of inorg. ions in the neighborhood of a protein ion are in correspondence with the cataphoretic expts. Calcns. of the mobilities of the ions of hemoglobin from the measurements of the charge and radius, Henry's formula (*C. A.* **26**, 17) being used, are in fairly close agreement with the observed mobilities. Victor R. Dietz

Influence of electrolytes on the electrophoretic mobility of serum albumin and hemocyanin. Paul Putzeys and Paul van de Walle. *Trans. Faraday Soc.* **36**, 32-8(1940); cf. *C. A.* **33**, 3897.—Serum albumin (horse) and hemocyanin (*Helix pomatia*) were investigated at 25° by the moving-boundary method. By the use of a solvent made of the same salt concns., but with ionic strength varying from 0.02 to 0.06, the isoelec. point of hemocyanin found is very nearly const.; that of serum albumin appears to shift 0.04 unit toward the alk. side for an increase of ionic strength from 0.03 to 0.06. Little success is obtained in correlating the electrophoretic mobility with the variation of acidity and the ionic strength of the soln. Victor R. Dietz

Observations at the electrophoretic moving boundary with Lamm's scale method. R. A. Kekwick. *Trans. Faraday Soc.* **36**, 47-52(1940); cf. *C. A.* **24**, 1261; **31**, 7722.—Use is made of the differences in the *n*s between the buffer and protein-buffer solns. The progress of electrophoresis of a 0.55% soln. of crystd. egg albumin at pH 7 is shown; the shapes of the curves differ in corresponding anode and cathode exposures, although the area under the curves remains appreciably const. Curves for a mixt. of egg albumin and lactoglobulin, for normal human serum and for the serum from a case of multiple myeloma show several max. in each case, some sharp and some flat. V. R. D.

Electroviscous effect in egg albumin solutions. Henry B. Bull. *Trans. Faraday Soc.* **36**, 80-4(1940).—Neither the Smoluchowski (*C. A.* **11**, 5) nor the Krasny-Ergen (*C. A.* **30**, 6621) equations, giving the increase in viscosity of a suspension of spherical particles as a result of the electrostatic potential on the particle, gives the right order of magnitude for the electroviscous effect with a purified egg albumin soln. (less than 1% concn.). The calcd. values are about 100 times those observed. Exptl. results indicate a pronounced electroviscous effect which is largely suppressed by electrolytes, namely, by 0.01 *N* NaCl on the basic side of the isoelec. point and by 0.02 *N* NaCl on the acid side. Victor R. Dietz

Effect of selenium on urease and arginase. C. I.

Wright. *J. Pharmacol.* **68**, 220–30(1940); cf. *C. A.* **32**, 9267[8].—Se in the form of selenite, selenate or diselenodiacetic acid inhibits the activity of urease, probably by oxidizing SH groups. Inhibition by selenite is immediate and increases rapidly with increase in concn., but does not go to completion. Inhibition by diselenodiacetic acid is progressive and goes to completion at very low concns. after sufficient time. Rat liver arginase activity is not affected by *in vitro* addn. of Se compds. The ingestion by the rats of Na selenite or seleniferous wheat does not decrease the liver arginase concn. The water content of livers taken from animals ingesting Se compds. is 5–10% greater than in controls. L. E. Gilson

Chemistry and physiology of glutenin. Emil Abderhalden. *Quaderni nutriz.* **6**, 248–55(1939).—A discussion. Helen Lee Gruehl

The origin and maintenance of optical activity in living matter. G. F. Gauze. *Biodynamica* No. **56**, 23 pp (1939); cf. *C. A.* **34**, 1039[8]. - A review. E. H.

Relationship of vitamins and enzymes. John Field, 2nd. *Contact Point* **17**, 172–80(1940). E. H.

Variations in energy conversion during cell partition (temperature measurements on live single cells). H. J. Trurnit. *Naturwissenschaften* **27**, 805–6(1939).—Thermocouples were constructed of 1–2 μ diam. and of "active mass" about 10^{-10} g. The thermoelectrically active part of these sounding elements is small relative to a red blood corpuscle. A standardization method was worked out to convert the readings from these couples to heat production in cal. per sec. Thus the course of mitosis could be followed quantitatively. Detns. were made with eggs of *Triton alp.* of 1 cu. mm. content and their parts after removal of the jelly shell. Other tests were made on sea-urchin eggs (*Psammechinus mil.*) of 0.0003 cu. mm. in a glass vessel of 0.4 cu. mm. content (5 to 100 per test). The sounding element was introduced centrally. The tests took place on a slide in a moist chamber, and a stereomicroscope, manipulator and thermostat were used. The sounding elements were 15 and 30 μ diam. The temp. variations in the cells are shown in curves *vs.* time, temp 20°. For sea urchin eggs a temp. rise of the order of $^1/_{50}$° commencing simultaneously with cell partition was observed, with a max. at about the time of finished partition, followed by a rapid decrease. Both rise and fall show minor maxima. Sepn. of plasma and nucleus therefore takes place with a more intensive energy conversion than the preceding development stage. This work is related to chemocytology. B. J. C. van der Hoeven

Activation and inhibition of alkaline phosphatases. R. Cloetens. *Naturwissenschaften* **27**, 806(1939).—Continuing previous work (*C. A.* **33**, 6366[6]; **34**, 1340[6]) C. studied the influence of Mn^{II} ions on alkali phosphatases in presence and absence of KF and KCN, 0.01 *M*. Intestinal phosphatase II, kidney phosphatase II and liver phosphatase I were used, Mn^{II} in concns. of 0.001 and 0.01 *M* activates both of these phosphatase species. With phosphatase I little or no (up to 20%) inhibition is found with 0.01 *M* KF or KCN at the lower Mn concn., no inhibition at all at the 0.01 *M* concn. With phosphatase II no inhibition is found with 0.01 *M* KF, 90% inhibition with 0.01 *M* KCN. B. J. C. van der Hoeven

Fluoride inhibition and metal activation of yeast phosphatase. L. Massart and R. Dufait. *Naturwissenschaften* **27**, 806–7(1939).—Yeast phosphatase which splits β-glycerophosphate at pH 6 to 7 optimally is sensitive to addn. of metals (Mg, Mn) like alk. phosphatases (cf. preceding abstr.). The yeast phosphatase is inhibited by fluoride and loses a large part of its activity on dialysis. Mg or Mn ions reactivate dialyzed enzyme. Fluoride affects the Mg reactivation more than that of Mn. Fluoride inhibition is considered due to complex formation, Mg is more likely to form metal complexes with F than Mn. Tabulated data are given. B. J. C. van der Hoeven

Aminopolypeptidases. Ernst Maschmann. *Naturwissenschaften* **27**, 819–20(1939).—The aminopolypeptidases of obligatory anaerobic bacteria (anaeropeptidases) are not of simple nature but contain several apoenzymes, changing in relative amts. depending on the origin of the enzyme. Bivalent Fe, sometimes Mn, functions as coenzyme. From bouillon cultures of *B. histolyticus* and *B. botulinus* were prepd. enzymes which after pretreatment with cysteine and 2 $FeSO_4$ decompd. leucylglycylglycine (LGG) and diglycylglycine (GGG) readily. $(NH_4)_2SO_4$ fractionation of these enzymes produced fractions which decompd. either LGG or GGG. Tabular data are given. The $(NH_4)_2SO_4$ solns. used varied in concn. from 50 to 75%. On treatment of the histolyticus enzyme pptd. with 75% $(NH_4)_2SO_4$ by MeOH at 0° and pH 7 there appears a ppt. at 75% MeOH concn. which splits only GGG readily and is inactive toward dipeptides and in proteolysis. The other fractions are inactive, hence MeOH irreversibly inactivates the LG and LGG apoenzymes. The pH optimum of the anaeroaminopolypeptidases is between 8.2 and 8.5. The aminopolypeptidases have no carboxyl group essential for their activity. B. J. C. van der H.

Mutability and physiological condition. Edgar Knapp. *Naturwissenschaften* **27**, 839–40(1939).—Differences in mutational behavior of the same genotype attributed to different physiol. conditions of the cell have been found repeatedly in the past, especially in the reaction of the cell to ionizing rays. It is suggested that the "physiological condition" causes differences in hydration stage of the genetic substance and thus brings about different stabilities. For the result of radiational influences a change in size of target due to more or less hydration is essential. Quant. work with x-rays of cells in different stages of swelling confirmed this view: in swollen cells the frequency of mutation due to radiation is larger than in normal cells. The change in sensitivity due to swelling is reversible as long as the swelling has not been continued too long. cf. Knapp, *Fortschr. Röntgenstr.* (Tagungsheft) **60** (1939); Kaplan, *Biol. Zentr.* and *Z. indukt. Abstammungslehre* in press. B. J. C. van der Hoeven

Interpretation of mitogenetic radiation as sensitized fluorescence. An experimental confirmation of Frankenburger's theory of mitogenetic radiation. A. G. Gurvich, L. D. Gurvich and A. A. Slyusarev. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 101–7(1939).—See *C. A.* **33**, 7829[5]. S. A. Karjala

Steric specificity of the peptidases of normal and carcinoma serums. (Preliminary.) E. Waldschmidt-Leitz and K. Mayer. *Z. physiol. Chem.* **262**, IV–VI(1939).—The peptidases of carcinoma serums show no choice between *d*- and *l*-peptides, whereas normal serums do. With *dl*-leucylglycine, *dl*-glutamylglycine and *dl*-glutamylglycine Et ester as substrates, normal serums produce 50% hydrolysis whereas carcinoma serums produce more than 50% hydrolysis. Milton Levy

Specificity of amino acid decarboxylase. Peter Holtz, Karl Credner and Hedwig Walter. *Z. physiol. Chem.* **262**, 111–19(1939); cf. *C. A.* **34**, 1338[6].—The enzymes which decarboxylate histidine, tyrosine and dihydroxyphenylalanine in organ exts. are shown to be separate entities. Exts. of various organs and organs of various species differ in their relative activities on the 3 substrates. In mixts. the actions on the substrates are additive and not competitive. The enzymes active toward histidine and dihydroxyphenylalanine are not adsorbed by kaolin whereas the tyrosine decarboxylase is. Milton Levy

Animal fat acid dehydrogenases and their codehydrogenases. III. Nature of the codehydrogenase. O. St. A. Konrad Lang and Hermann Mayer. *Z. physiol. Chem.* **262**, 120–2(1939); cf. *C. A.* **34**, 1337[9].—The codehydrogenase for fat acid dehydrogenation in muscle exts. is shown to be muscle adenylic acid. Inosinic acid, adenosinetriphosphoric acid and muscle adenosine are equally effective in equimol. amts. Yeast adenylic acid is not effective except at much higher doses. Adenine is not effective. **IV. The reaction product of dehydrogenation of stearic acid and the supposed biological importance of fat acid dehydrogenase.** O. St. A. Konrad Lang and Franz Adickes. *Ibid.* 123–7.—O_2 treatment of the product of dehydrogenation of stearic acid by liver or muscle ext. indicates that oleic acid is formed and not an α-β-unsatd. octadecenic acid. Milton Levy

Carboligase. Belá Tankó and László Munk. *Z.*

physiol. Chem. **262**, 144–57(1939).—Expts. indicating that carboligase is not an independent entity in pea meal are described, supporting Discherl's position (*C. A.* **32**, 4182[8]) and contradicting Tomiyasu (*C. A.* **31**, 8566[8]). The pH optimum is the same for decarboxylation of pyruvic acid (carboxylase) and for acetoin formation (carboligase). In the absence of pyruvate and in the presence of AcH, formation of acetoin is limited by the rate at which pyruvate is formed from carbohydrate. If pyruvate is added the acetoin formation depends only on the rate of decarboxylation. The inhibitory action of $CHCl_3$ on carboxylase is not sufficiently different from that on carboligase to establish their independence. Inhibition of acetoin formation by F^- or ICH_2COOH is slight when pyruvate is present but is great when it is not. Since these inhibit pyruvate formation but not carboxylase, the acetoin formation depends on the carboxylase action. The acetoin formed in the presence of AcH and the poisons is adequately accounted for by the rate of pyruvic acid breakdown as indicated by the CO_2 production under these conditions. Milton Levy

Polarographic investigations of proteins. I. Polarography as a method. Caspar Tropp. *Z. physiol. Chem.* **262**, 199–209(1939).—The method is described. **II. Polarographic investigation of the changes of state of fibrinogen.** Liselotte Juhling, Caspar Tropp and Edgar Wohlisch. *Ibid.* 210–24.—Purified fibrin gives polarographs similar to those of other S-contg. proteins in a $CoCl_2$-NH_4Cl-NH_4OH soln. The typical double wave obtained from proteins is present. In 10% urea as a solvent heat denaturation increases the height of both waves. Fibrinogen treated with thrombin does not show this increase unless the urea is reduced to 3%. Trypsin digestion increases both steps and after long action the first step disappears and the second becomes flattened. The first step is related to the peptide bond, the second to the cystine of the protein. **III. Albumin, globulin, fibrinogen, plasma and serum.** Caspar Tropp, Liselotte Juhling and Fritz Geiger. *Ibid.* 225–42.—The two steps common to protein polarographs are demonstrated with serum albumin and globulin and, as with fibrinogen, both steps are increased, the first 10% and the second 50%, by heat denaturation in 10% urea. Curves obtained on geometrical series of dilns. of albumin, globulin, fibrinogen, plasma and serum are given. These show that each protein is characterized by a maximal concn. for which an analysis of the curve is possible: 3.2% in the case of globulin, and 0.48% in the case of fibrinogen and other values are intermediate. On diagrams of the heights of the first and second waves against concn., specific forms are shown for each material but each shows a characteristic crossing concn. where the second wave diminishes to the height of the first and then falls below it. The crossing concn. is 0.0094% for albumin, 0.002% for globulin, 0.02% for fibrinogen. The forms of these diagrams up to this point vary from protein to protein, both waves becoming higher as the concn. increases. The curves for plasma and serum show the same characteristic forms and are interpreted as summations of the curves of the individual constituents. M. L.

Pyrophosphate inhibition of succinodehydrogenase. L. Massart, R. Dufait and G. van Grembergen. *Z. physiol. Chem.* **262**, 270–4(1940). —That pyrophosphate inhibition of succinodehydrogenase is not analogous to malonate inhibition of this enzyme, as claimed by Lelour and Dixon (*C. A.* **31**, 6679[9]), and is analogous to F^- inhibition is supported by exptl. findings. Pyrophosphate and F^- inhibitions are increased as the reaction mixt. is made more acid, malonate inhibition is nearly const., perhaps slightly more as the soln. is made alk. Addn. of fumaric acid removes malonate inhibition; it has no effect on pyrophosphate inhibition. Both F^- and pyrophosphate inhibitions are due to formation of metal complexes. Succinodehydrogenase is probably a metalloprotein. M. L.

***N*-Acetylglucosamine and blood proteins.** Henri Bierry, Bernard Gouzon and Collette Magnan. *Compt. rend.* **210**, 120–2(1940).—See *C. A.* **33**, 3863[1]. D. A. M.

Biochemical studies on carbohydrates. LIII. Glucosamine as a glycogenetic substance in organisms. Masato Yositake. *J. Biochem.* (Japan) **30**, 423–37(1939); cf. *C. A.* **34**, 1046[1].—Feeding glucosamine to male rabbits treated with phlorizin caused a greater extra glucose excretion than was obtained with glucose, leading to the conclusion that the amino sugar is a glucose former. **LIV. Hyperglucemia and glucosamine injection and the mechanism of its occurrence.** *Ibid.* 439–49.—The hyperglucemic effect of subcutaneous injection of glucosamine is not due to stimulation of the nervous center for carbohydrate regulation because it is not affected by double splanchnectomy, nor is it due to a disturbance in carbohydrate metabolism, since the activity of various oxidase enzyme systems was also found to be unaffected. It is concluded, therefore, that the hyperglucemia is due to glucose derived from the amino sugar. **LV. Urinary mucoid.** Tadasi Kobayasi. *Ibid.* 451–8.—Urinomucoid obtained from urine contains an acetylglucosaminegalactose (1:1) complex as the prosthetic group. This substance represents both the acid-sol. and water-sol. mucoid fractions described by Morner, which K. finds to be identical with each other and, therefore, designates urinomucoid. S. Morgulis

The use of radioactive isotopes of the common elements in physiology. G. Hevesy. *Phys. Rev.* **57**, 240–1(1940); cf. *C. A.* **33**, 8646[7].—Objections to the use of radioactive indicators in detg. the movement of ions through cell membranes, particularly those based on the denaturation of proteins by the radiation, are not justified. G. M. Petty

Studies of human nervous and related tissue by the Röntgen-ray diffraction method and the petrographic microscope. Lawrence Reynolds, K. E. Corrigan and Henrietta Hayden. *Am. J. Roentgenol. Radium Therapy* **43**, 81–92(1940).—Standard methods of x-ray diffraction studies of non-cryst. substances were applied to nervous and related tissues; diffraction patterns obtained in 30 cases are reproduced. The diffraction work was supplemented by observations with a standard petrographic microscope and polarized light; 15 color reproductions of these slides are given. Orientation can be noted in nerve trunks, which have a highly specialized directional function, in dural tissue and in the periosteal layer. Extd. brain tissue gives a pattern similar to that of neuroproteins. Gray and white matter of the cerebrum give slightly different patterns, the differences being shown clearly after drying. E. H. Quimby

Chemical structure and its relation to growth and development. Frederick S. Hammett. *Am. J. Roentgenol. Radium Therapy* **43**, 266–70(1940).—Growth is an expression of reaction between chem. compds. The present discussion relates to the components of the cellular proteins, both cytoplasmic and nuclear, e. g., amino acids and the purine and pyrimidine compounds of nucleic acid, which comprise the bulk of living matter of all organisms. In growth, differentiation is a chem. specialization of the cell structure, especially in the proportion and arrangement of the constituent amino acids, which, with other nitrogenous compds., supply building substance and energy. Dynamic effects of the various acids are outlined. The effects of adding CH_2 and OH groups to mols. are stated, the former to increase energy, the latter to decrease toxicity. The replacement of a H of an amino acid by a sulfhydryl may give a compd. that acts as a stimulus to cell increase in no. When two such groupings unite with loss of H to form a disulfide, the compd. is no longer stimulating. When this normal oxidation continues to the point of a compd. in which the S carries an O, retardation of cell increase in no. occurs. E. H. Q.

Biological action of metals at a distance. A. E. Roffo, Jr. *Bol. inst. med. exptl. estud. cancer* **16**, 55–76(1939).—The action of metals at a distance on tissue cultures *in vitro* of fibroblasts from embryonic rat or chicken heart and of fibroblasts from spindle cell sarcomas is shown by growth inhibition, which is not related to the at. wt. of the metals used. The inhibitory action is greater on the neoplastic tissues than on normal fibroblasts. Al, Fe, Ni, Cu, Zn, Se, Cd, Sn, W, Au and Pb do not inhibit the growth of normal fibroblasts, but Hg, La, Mg and Be do.

Al, Ni, Cu, Zn, Se, Cd, Sn and Au slightly inhibit sarcomatous fibroblasts but Be, Mg, Fe, Sb, La, W, Hg and Pb show a strong inhibition. Felix Saunders

Photodynamically induced cation permeability and its relation to hemolysis. Hugh Davson and Eric Ponder. *J. Cellular Comp. Physiol.* **15**, 67–74(1940); cf. *C. A.* **33**, 6888⁶.— The photodynamic hemolysis produced by irradiating rabbit red cells in the presence of Rose Bengal is accompanied by an escape of K from the cells, both during the period of irradiation and during the period of "after-light hemolysis" which occurs after the irradiation is discontinued. During the period of illumination hemolysis and K escape are inhibited by the addn. of serum and Na_2SO_3, but neither serum nor sulfite has any inhibitory effect on the after-light hemolysis. The after-light hemolysis and K escape have a Q_{10} not greater than unity, which suggests that the phenomenon has a phys. rather than a chem. basis. The hemolysis may be due to a secondary swelling of the irradiated cells brought about by a permeability to K setting up an osmotic pressure difference Felix Saunders

Photodynamic hemolysis with monochromatic light: the reciprocity law. Harold F. Blum and Howard W. Gilbert. *J. Cellular Comp. Physiol.* **15**, 75–84(1940).— A method for study of photodynamic hemolysis by means of monochromatic radiation is described. Errors in the use of photometric methods for measuring percentage hemolysis are discussed. A method which uses delayed hemolysis as a criterion for estg. the photochem. process in photodynamic hemolysis is described. This fundamental photochem. reaction follows the reciprocity law. **Quantum requirements for photodynamic hemolysis.** *Ibid.* 85–93.— Photodynamic hemolysis is independent of dye concn. The same no. of quanta per red cell are required to produce delayed hemolysis after 24 hrs. The no. of quanta absorbed by a dye mol. in this process is inversely proportional to the concn. and ranges from a few to thousands of quanta. The dye must act in a cyclic process, probably transferring its energy to substrate which then reacts with O, the dye returning to its normal state. Felix Saunders

Liesegang zone formation as a model for organic rhythms. E. Kuster. *Kolloid Z.* **89**, 123–4(1939).— Banding in living tissues can result from both exogenous and endogenous forces Felix Saunders

Zone formation in the protoplasm of vegetable cells. Lisbeth Schorr. *Kolloid-Z.* **89**, 161–2(1939). F. S.

Double refraction of elastic fibers. W. J. Schmidt *Kolloid-Z.* **89**, 233–7(1939).— Methods for demonstrating the properties of yellow elastic fibers are described. Felix Saunders

Action of centrifugation on the viscosity of living protoplasm. Ernst Kuster. *Kolloid-Z.* **89**, 237–8(1939); cf. *C. A.* **33**, 8697². Felix Saunders

Crystalline salmon pepsin. Earl R. Norris and Daniel W. Elam. *Science* **90**, 399(1939).— A globulin-type protein of high proteolytic activity was isolated in cryst. form from the stomach mucosa of the king salmon (*Onchorhyncus tschawytscha*). The optimum pH for digestion of hemoglobin is 2.2. The isoelec. point is pH 1.9. Prepns. of identical potency were obtained either by direct acid extn. or by alk. extn. of the zymogen. Alk. extn. gives larger yields. Felix Saunders

Coenzyme concentration of tissues. Frederick Bernheim and Anton v. Felsovanyi. *Science* **91**, 76(1940).— By means of *Hemophilus parainfluenzae* the concn. of coenzymes in rat tumor was compared with the concn. in normal tissues. Tumors were tested 10–37 days after inoculation. All showed very low values as compared with normal tissue and there was no variation with the age of the tumor. Embryonic tissue also gives very low values for coenzymes. After birth the values rise rapidly and reach the normal adult range in about a week. F. S.

Sensitive crystallization. Ehrenfried Pfeiffer. *Chem. Products* **3**, 21–5(1940).— A study was made of the effect of small amts. of various substances on the crystn. of $CuCl_2$ from thin films of soln. The added substances include exts. of plants, animal organs, milk, yeast and blood. Different crystn. patterns were produced by exts. of a healthy plant from those produced by a fungus-diseased plant. In general, exts. of "normal" organs produce fewer centers and more long crystal rays, while the exts. of diseased organisms produce more centers, more incrustations and shorter rays. This may be due to a change in the colloidal nature of the added substance resulting from the change of metabolism in the diseased organism. Addn. of fresh milk produces a one-center sym. crystn., milk heated just to boiling produces a slightly disturbed picture, and milk boiled for 20 min. produces a many-centered asym. picture. The pattern produced by yeast depends on the nutritive broth on which it is grown and the kind of fertilizing applied to test plants can change the crystn. pattern made with exts. of these plants. Blood from patients having certain diseases produces const. and typical forms. Thus, blood from tuberculosis patients produces a type of cross formation of the centers, and blood of cancerous origin yields a one-sided double wing formation. 13 references and 18 crystn. pictures. Leopold Scheflan

Structural interpretation of the acidity of groups associated with the hemes of hemoglobin and hemoglobin derivatives Charles D. Coryell and Linus Pauling. *J. Biol. Chem* **132**, 769–79(1940).— Analysis of electrode potential and magnetic susceptibility data have established the existence of an acid group (pK 5.3) interacting with heme in ferrihemoglobin (methemoglobin). The magnetic susceptibility of ferrihemoglobin has been completely correlated with heme-linked acid group ionizations for the pH range 5–12. The spectroscopic and magnetic characteristics of the 3 heme-linked acid groups of ferrihemoglobin (pK 5.3, 6.65, 8.10), the 2 of ferrohemoglobin (pK 5.25, 7.81), and the 2 of oxyhemoglobin and carbonmonoxyhemoglobin (pK 5.75, 6.80 for both) for the range pH 4.5–9.5 are presented It is postulated that one acid group is a histidine imidazolium ion in poor position for electrostatic coordination of the basic form with the Fe atom. The second acid group is the imino group of a histidine residue whose 3-N atom is strongly coordinated by either an essentially ionic or an essentially covalent bond with the Fe atom. The third acid group of ferrihemoglobin is the Fe atom itself, which may add OH ion, or H_2O coordinated to the Fe atom, which may lose a proton. Changes in acidity caused by oxygenation or oxidation are thus given a structural interpretation. D. S. S.

Properties of viruses W. M. Stanley. *Medicine* **18**, 431–42(1939); cf. *C. A.* **34**, 808⁵.—The recent chem., phys., immunological and biol. work on viruses is reviewed with emphasis on the tobacco mosaic virus. Present data indicate the latter is a conjugated protein, contg. 95% protein, 5% nucleic and no lipoid. The amino acids found include arginine, aspartic acid, cysteine, *d*-glutamic acid, leucine, lysine, phenylalanine, proline, serine, tyrosine and tryptophan, but no measurable amt. of alanine, histidine or glycine. The nucleoprotein contains C 50, H 7, N 16, S 0.24, probably in sulfhydryl form, and P 0.6%. It is homogeneous in sedimentation and electrophoresis, and with an isoelec. point at pH 3.5, density of 1.37, S of 17.1×10^{-13} cm. sec.$^{-1}$ dyne^{-1}, D of 3×10^{-8} sq. cm. sec., and rotational diffusion const. of 25 sec.$^{-1}$ at 0°. It exhibits double refraction of flow, elec. double refraction and gives an x-ray diffraction pattern interpreted as being due to rods about 15 mμ in cross section. The mols. are estd. and found to be about 300–400 mμ in length and about 12 mμ in cross section. Specific precipitin and anaphylaxis reactions are obtained. The activity and properties given are const. regardless of the source of the starting material. Changes caused in the chem. or phys. properties cause changes in virus activity. Some other viruses are spherical in mol. shape. F. B. Seibert

Crystallizable virus proteins. J. Magrou. *Rev. path. vég.* **26**, 109–23(1939); *Rev. Applied Mycol.* **18**, 812.— This review discusses the recent investigations of Stanley, Bawden, Pirie and others on the nature of the cryst. proteins assocd. with virus diseases and their possible identity with the viruses themselves. Oden E. Sheppard

The chemical properties of ascorbic acid oxidase. III.

Tetutaro Tadokoro and Naomiki Takasugi. *J. Chem. Soc. Japan* **60**, 188–90(1939); cf. *C. A.* **33**, 2154⁷.—A substance having high *AAO* (*AAO* = ascorbic acid oxidase) activity is prepd. from pumpkin: Yellowish juice obtained from the edible part of pumpkin is filtered through a pulp layer and pptd. with acetone. Aq. soln. of the ppt. is satd. with $(NH_4)_2SO_4$ to obtain crystals having the albumin reactions and strong *AAO* activity. Its aq. soln. is then dialyzed for 10 days and repptd. with acetone. The dried ppt., like cucumber protein, has low C and high P content, indicating similarity to glucoproteid or lecithoglucoproteid. Contents of amino N and arginine N, however, indicate similarity to plant protein, but low humin N content is against the supposition. Analytical results: C 43.01, H 7.22, N 13.36, P 0.52%. Of N compds. amido N is 8.45%, humin N 8.32%, monoamino N 54.85%, diamino N 14.05%, arginine N 17.85%. Equal amts. of filtered pumpkin juice and citrate buffer of pH 7.4 are added to 0.125% *AA* (*AA* = ascorbic acid) soln. The soln. is aerated for 1 hr. to let the action of *AAO* be completed. After filtration the oxidized soln. is shaken with porcelain clay for 2 hrs. The clay is filtered off, washed with water and finally with acetone, yielding a dry white powder. 0.9 g. of the powder is added to 20 cc. buffer of pH 7.4. Six mixts. are made. Two (I) of such mixts. are kept at 37° for 2 hrs. The other two (II) are treated similarly after the addn. of 1 cc. rabbit meat ext. with 0.85% NaCl soln. (glutathione). The remaining 2 mixts. (III) are treated similarly after the addn. of 1 mg. com. pancreatin. Four cc. filtrate of each of these mixts. is titrated with Tillmann's indophenol soln. after the addn. of 1 cc. each of sulfosalicylic acid and metaphosphoric acid solns. A blank expt. is carried out for each of solns. II and III, and the results are corrected. The consumptions of the dye soln. for I, II and III are, resp., 0.62, 1.55 and 1.10 cc. The differences in consumption are due to the combination of *AA* with protein or to inactivation of *AAO* by protein digestion. *AAO* distribution in cauliflower was investigated by a similar method, and the inner leaves were found to contain the greatest and the outermost the smallest amts. IV. *Ibid.* **60**, 325–7(1939). —Protein having *AAO* activity is isolated from the aq. ext. of the leaves of cauliflower by the same method as has been used for pumpkin juice. Ppt. I appearing during dialysis is sepd. from the soln. The soln. is then treated with acetone to obtain ppt. II. Average analytical data for I and II are as follows: I C 43.412, H 6.085, N 8.771, P 0.91%; II C 44.479, H 6.390, N 7.706, P 1.207%. The P content of cauliflower protein is higher than those of cucumber and pumpkin and corresponds to that of nucleoalbumin. The low content of C suggests that the protein is a conjugated protein. The velocity const. of the *AA* oxidation by *AAO* is detd. as follows: 1 cc. 2.5% *AA* soln., 50 cc. citrate buffer of pH 5.8 and 4 cc. soln. of acetone ppt. of cauliflower juice are mixed and the total vol. is made up to 100 cc. Twenty-five cc. of the soln. is kept at 37°, 3 cc. of which is titrated with the indophenol soln. at 30 min. intervals. The results indicate that the oxidation is a unimolecular reaction with respect to *AA*, the value of the velocity const. being about 231×10^{-5}. Egg and rice globulins have been found to inhibit *AA* oxidation. The inhibition is due probably to glutathione or cystine rather than to adsorption by protein of *AA*.
K. Shinohara

Biochemical changes in irradiated tissues. I. The effect of x-rays on the metabolism of incubated hen eggs. Hideo Komoti. *J. Oriental Med.* **31**, 963–1005(German abstr. 57–60)(1939).—When hen eggs are irradiated with hard x-rays (600 r.) at the 5th day of incubation, 20% died, and those surviving show abnormal growth and development. The analysis of the white, yolk, amniotic fluid and embryo for total N, albumin, globulin, residual N, amino acid and uric acid for every 2 days after irradiation shows that protein metabolism is greatly disturbed. Data for detailed analysis are given. The results of irradiation with small amts. of the x-ray (200 r.) are also included. S. T.

Amine oxidase and benzedrine. Hermann Blaschko. *Nature* **145**, 26–7(1940); cf. *C. A.* **32**, 6275⁵.—Substances of the structure $RCH_2CHNH_2CH_3$, e. g., veritol and benzedrine, are much stronger inhibitors of amine oxidase than those of the structure $RCHOHCHNH_2CH_3$, e. g., ephedrine. A comparison with the awakening properties of these substances in the living animal shows that there is agreement between *in vitro* effect and pharmacol. action.
E. D. Walter

Dihydroxymaleic acid oxidase action of peroxidases. B. Swedin and H. Theorell. *Nature* **145**, 71-2(1940); cf. Banga and Szent-Györgyi, *C. A.* **32**, 9105⁴.—This enzyme is a hemin protein and it can act in a different manner with different substrates. There is not sufficient reason to assume that the dihydroxymaleic acid oxidase and the peroxidase are different enzymes. E. D♦W.

Wave-length effect in the reaction of human skin to x- and γ-radiation. Joseph S. Mitchell. *Nature* **145**, 105–6(1940).—In the production of moist desquamation of normal human skin, 0.7–0.8 roentgen unit of x-radiation of effective wave length 145 x. u. is equiv. to 1 roentgen unit of γ-radiation of effective wave length 15 x. u. Attempted phys. and chem. explanations of this fact are not entirely adequate. E. D. Walter

Mechanism of enzymic decarboxylation. H. Weil-Malherbe. *Nature* **145**, 106–7(1940).—A mechanism is proposed for the enzymic decarboxylation of pyruvic acid. It involves the formation of a Schiff base from cocarboxylase and pyruvic acid followed by an intramol. oxido-reduction leading to acetyldihydrococarboxylase. It is suggested that this compd. is oxidized in animal tissues and in certain bacteria by a specific carrier, whereas it undergoes a second intramol. oxido-reduction with yeast carboxylase resulting in the formation of the Schiff base of acetaldehyde. B—METHODS AND APPARATUS

Glenn E. Cullen

It is with deep regret that we announce the death on April 11 of Dr. Glenn E. Cullen, who has served faithfully and with high interest and devotion as assistant editor in charge of this section of *Chemical Abstracts* since early in 1937. Dr. Cullen was a careful editor and his untimely death at the age of 50 is a great loss. His work for *Chemical Abstracts* was only a small part of his useful activity in the interest of biochemical and pediatric research.

Imidazole buffer; its use in blood-clotting studies. Edwin T. Mertz and Charles A. Owen. *Proc. Soc. Exptl. Biol. Med.* **43**, 204–5(1940).—Stable solns. of imidazole and HCl covering the pH range 6.2–7.8 are described. They are useful buffers for reactions which require the presence of Ca ion. They have no effect on either the conversion of prothrombin into thrombin or on the action of thrombin on fibrinogen. L. E. Gilson

C—MICROBIOLOGY

LAWRENCE H. JAMES

The existence in the tubercle bacillus of complex phosphatidic acids constituted from glycerophosphoric acid joined by esterification to fat acids on the one hand and to nonnitrogenous polyalcohols on the other. Michel A. Macheboeuf and Marguerite Faure. *Compt. rend.* **209**, 700-2(1939).—The Me_2CO-insol. phosphatides of the tubercle bacillus on treatment with MeOH and Ac_2O yield H_2O-sol. Na, Ca and Mg salts of complex phosphatidic acids (I) having 0.15% N and about 2.8% P. These salts are insol. in Me_2CO and sol. in Et_2O. The free acids are insol. in H_2O and sol. in Me_2CO and Et_2O. Prolonged treatment of I with *N* H_2SO_4 liberates fat acids and H_2O-sol. organophosphoric acids (II). II are not precipitable by Pb(OH)OAc except in the presence of NH_3 or by Pb$(OAc)_2$. Titration shows II to have 4 acid groups to 3 atoms of P. Hydrolysis of I with 5% H_2SO_4 at 120° yields glycerophosphoric acid (III) which is precipitable by Pb(OH)OAc. Twenty-eight % of oses and inositol are set free by acid hydrolysis. Hydrolysis with hot baryta liberates nonreducing osides which on secondary acid hydrolysis yield oses. III is therefore united to the oses by esterification. The inositol may be similarly united with III or may be a constituent of the oside grouping. The fixation of complement is ascribed to the haptenic activity of the complex phosphatidic acids. Rachel Brown

Carbohydrate yeast fermentation balance. Fermentation of inulin without previous hydrolysis. Theoretical and practical deductions. Raymond Guillemet and Hélène Leroux. *Bull. soc. chim. biol.* **21**, 1217-41(1939); cf. *C. A.* **33**, 8351⁹.—Inulin was fermented slowly by Lala yeast although no hydrolysis of inulin to fructose could be detected. CO_2 and EtOH were formed in equimol. quantities. The yield of glycerol was 3.7-4.0% of the wt. of the inulin consumed. About 30% of the inulin was converted into unidentified products. L. E. Gilson

Relation between virulence and antigenic structure of Salmonella. A. Boivin. *Compt. rend. soc. biol* **132**, 370-4(1939). The glucide-lipide antigens from highly virulent (for mice) and slightly virulent strains of the smooth form of Aertryeke's bacillus were identical. The reason for the difference in virulence is unknown. L. E. Gilson

Chemical properties and physiological actions of Triturus embryonic toxin. D. B. Horsburgh, E. L. Tatum and V. E. Hall. *J. Pharmacol.* **68**, 284-91(1940).—The embryonic toxin of the newts *Triturus torosus*, *T. similans* and *T. rivularis* is sol. in water and EtOH but insol. in Et_2O, $CHCl_3$ and other org. solvents. It is relatively stable to heat in neutral or slightly acid solns. but readily inactivated if alk. It is neither an alkaloid nor a substance related to the toad cardiac poisons. The purest specimen prepd. had an activity of 75,000 mouse lethal doses per g. It acts through the central nervous system. A similarly acting toxin is found in certain skin glands of the adult *Triturus*. L. E. Gilson

Characteristics of cultures of the genus Pasteurella. E. Savino, A. Aldao and B. Anchezar. *Rev. inst. bacteriol. dept. nacl. hig.* (Buenos Aires) **9**, 110-21(1939).—Numerous strains of *Pasteurella pestis*, *Pasteurella pseudotuberculosis* and unidentified species of *Pasteurella* were studied. All reduced nitrates. All produced catalase, H_2S and NH_3. Some of the unidentified strains produced indole. No strain formed acetylmethylcarbinol. All fermented glucose, fructose, mannose, galactose, mannitol and sorbitol with formation of acids. None fermented lactose, raffinose, inulin, melezitose, dulcitol, erythritol, inositol or arabitol. Glycerol, sucrose, rhamnose, maltose, xylose, arabinol, adonitol, trehalose, salicin and starch were converted to acids by some strains and not attacked by others. Forty references. L. E. Gilson

Mycological study of the first Argentine case of black grain Madura foot. Pablo Negroni and Juan A. Tey. *Rev. inst. bacteriol. dept nacl. hig.* (Buenos Aires) **9**, 176-89(1939).—The causative organism, *Aspergillus* (*Eurotium*) *chevalieri* Mangin, does not ferment sugars but uses galactose, sucrose, maltose, dextrin, mannitol, sorbitol, glucose, mannose, fructose and, less readily, lactose and inulin, for growth purposes. It can also utilize EtOH as the sole source of C. It does not hydrolyze starch, cellulose or fats. As sources of N it utilizes peptone and asparagine more readily than urea, nitrates or $(NH_4)_2SO_4$. It does not reduce nitrates and has no bacteriolytic action. It does not produce indole, acetylmethylcarbinol or H_2S. It liquefies gelatin slowly. L. E. Gilson

Culture media from spinach leaves. A. M. Besredka and Eva Salomon. *Ann. inst. Pasteur* **1939**, No. 2, 144; *Lab. Prakt.* (U. S. S. R.) **14**, No. 9-10, 12(1939).—Grind the spinach leaves in a meat chopper, press out the liquid, bring it to boiling (the color of the liquid changes to dark brown with the formation of a ppt.), remove the ppt. by filtration, alkalize the liquid, keep it for 20 min. at 120°, remove the formed ppt. by filtration through paper and sterilize in an autoclave for 20 min. at 115°. In its chem. compn. (quant. data are given), its reaction (pH = 7.6-8.0) and its other properties the spinach juice was suitable for the growth of all investigated microbes (aerobes as well as anaerobes) and for the prepn. of tuberculin. W. R. Henn

A new method of culturing sputum on solid media using carbon dioxide for the isolation of pneumococci. W. J. Auger. *Brit. J. Exptl. Path.* **20**, 439-42(1939).—A "sputum plate" technique for the isolation of pneumococci is described in which sputum is cultured on blood agar plates in the presence of extra moisture and a high concn. of CO_2. In such conditions a max. growth of pneumococci is possible in 15 hrs. CO_2 has also a stimulating effect on the growth of other respiratory pathogens. H. F. H.

A reaction between the lethal toxin of Cl. welchii (type A) and human serum. F. P. O. Nagler. *Brit. J. Exptl. Path.* **20**, 473-85(1939).—A reaction is described between the lethal toxin of *Cl. welchii* (type A) and normal human serum in which the serum becomes opalescent. When the opalescent serum is centrifuged, a fatty material rises to the surface. The reaction is specifically inhibited by *Cl. welchii* antitoxin. The reaction can also be observed if *Cl. welchii* of any type (A, B, C or D) is grown in a mixt. of normal human serum or broth. This cultural reaction has been shown to be specific for *Cl. welchii*, and it is specifically inhibited by *Cl. welchii* antitoxin. The lethal action of *Cl. welchii* (type A) can be titrated by means of the reaction, the activity of the toxin in bringing about the change in human serum running parallel to its toxicity for mice. *Cl. welchii* (type A) antitoxin can likewise be titrated, the inhibiting action of the antitoxin *in vitro* running parallel to its neutralizing action *in vivo*. Harriet F. Holmes

Physical and chemical examination of vaccinia virus. A. S. McFarlane, M. G. MacFarlane, C. R. Ames and G. H. Eagles. *Brit. J. Exptl. Path.* **20**, 485-501(1939).—The degree of hydration of the particle in homogeneous suspensions of the elementary bodies of vaccinia virus has been measured by a partition method; the particle has large amts. of H_2O assocd. with it in the form of an atm. which is not penetrated by sucrose and egg albumin. Elementary bodies can be dried, extd. with ether or benzene and resuspended in an aq. medium to the same degree of dispersity as the original homogeneous suspension without detectable loss in infectivity. The residual particle, which must be considered to be the virus, contains lipoid material which can only be removed by alc., as well as protein, carbohydrate and nucleic acid. The weight of evidence is against the conception that the virus particle is limited by a semipermeable membrane functioning on osmotic principles, and it is more in keeping with the properties of the particle to postulate a rigid or semirigid structure akin to a giant protein mol. H. F. Holmes

Alum-precipitated diphtheria toxoid. F. V. Linggood. *Brit. J. Exptl. Path.* **20**, 502-11(1939).—The addn. of alum in varying amts. to diphtheria toxoids made from broths of high and low N content has been investigated with particular regard to the purities of the resulting ppts. Toxoids of low N content (2.0-2.4 mg. per cc. give alum ppts. of higher purity than toxoids having a higher N con-

tent (5.0-6.0 mg. per cc.); this is especially the case when the ppt. is eluted with ½% $Na_2HPO_4.12H_2O$. Treatment of toxoids of low N content with charcoal prior to alum pptn. results in a considerable increase in the purity of the alum ppts., and ppts. of a purity of 700-800 L_f units per mg. N have been made by this method. Ppts. of even higher purity can be made if the toxoid is purified more extensively before pptn. After charcoal treatment and ultrafiltration of toxoids made from broths of low N content, alum ppts. of a purity of 1300-1400 L_f units per mg. N have been produced, providing a base is added in a convenient form such as $NaHCO_3$ prior to pptn. Harriet F. Holmes 1

Actinomyces: their biochemical reactions as aids in their classification. I. Reduction of nitrates. L. M. Ghosh, S. Ghosh, N. R. Chatterjee and A. T. Dutt. *J. Indian Botan. Soc.* **17**, 279-86(1938).—The reduction of nitrate to nitrite by *Actinomyces* (including not only the ray-fungi but also those grouped under *Discomycetes*, *Streptothrix*, *Nocardia*, etc.) in Czapeck's synthetic liquid medium was studied. Max. reduction was usually obtained at the end of the 3rd week. On the basis of the no. of cc. of standard nitrite soln. (0.001642 mg. NO_2 per cc.) equiv. to 5 cc. of the samples tested the *Actinomyces* could be divided into 3 main groups, namely, those showing (1) little or no reduction, below 0.5 cc. at the end of the 3rd week, (2) moderate reduction, 0.6-20 cc., (3) strong, more than 20 cc. K. D. Jacob 2

Fermentation of carbohydrates by the microbes of the dysentery group. M. I. Kanevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 36-44(in English, 44)(1939).—Microorganisms of the Flexner-Hiss-Strong group which do not ferment sucrose within 10 days do so readily when they are cultivated on peptone-water either in the presence or absence of sucrose. The same result is obtained in cultures in aq. solns. after a preliminary incubation for 5 days of the agar cultures in a thermostat. S. A. K. 3

The determination of small amounts of dysentery antitoxin. M. A. Zchkina and T. A. Gogoleva. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 52-61(in English, 61)(1939).—A broth of Shiga toxin is dild. to contain 1-2 lethal doses/cc. and titrated with increasing dilns. of a standard serum. The antitoxin equiv. is defined as that amt. of antitoxin which causes 20-40% mortality in combination with 2 lethal doses of toxin. The titer of an unknown serum can then be detd. by comparison with the standard. Differences in the titration of 5 antitoxic dysentery serums by the ordinary and "mero" methods do not exceed 22%. Since the toxin weakens with time owing to toxoid formation its concn. must be checked with standard serum from time to time. S. A. Karjala 4

Reinfection in typhoid fever with strains of different antigenic structure. I. The invasion capacity of typhoid fever strains of different virulence. E. G. Mehnik. *Bull. biol. méd. exptl U. R. S. S.* **8**, 231-3(1939)(in English).—Guinea pigs injected with various strains of typhoid bacilli were sacrificed 1, 3, 7, 10, 14 and 24 days after injection. The survival time of the Ty_2 (Vi) strain was 24 days in the skin at the site of injection, in the nearest lymph gland and in the tracheobronchial gland, 15-24 days in the lungs, spleen and kidneys, 10-15 days in the liver and mesenteric glands, 3-10 days in the blood, urine and bile, and 0 days in the bone marrow. The O_{901} strain was found for 24 days only at the site of injection and the nearest lymph gland, for 10 days in the liver, and 3-10 days in the other organs. Cultures of the blood and bone marrow were always sterile. Strains 705 and 679 of medium virulence showed a slightly greater survival capacity than O_{901}. The virulence of a typhoid strain seems to coincide with its invasion capacity. **II. Reinfection experiments.** *Ibid.* 234-6(in English).—Reinfection of guinea pigs with the Ty_2 strain 2 months after a single injection of the same strain led to survival of the organisms only at the site of injection and in the nearest lymph gland. Less edema and hyperemia of the skin were observed on the 2nd injection. The same results were observed when the O_{901} strain was used for injection and reinjection, and when the Ty_2 strain was used for injection and O_{901} for reinjection. When the O_{901} strain was used for injection and Ty_2 for reinjection, however, a pronounced invasion capacity was observed, indicating that O_{901} does not produce immunity toward Ty_2. In all cases pos. cultures were obtained from the blood and the bile. Strains 705 and 679 of medium virulence produced immunity both to the homologous strain and to each other. S. A. Karjala 5 6 7 8 9

The carotenoids of Mycobacterium phlei. Yosiharu Takeda and Tatuo Ota. *Z. physiol. Chem.* **262**, 168-70 (1939); cf. *C. A.* **33**, 4642[8].—From 870 g. of dry *Mycobacterium phlei* 2.5 mg. of cryst. leprotin was obtained. This is probably the material said by Chargaff (*C. A.* **28**, 1071[3]) and by Ingraham and Steenbock (*C. A.* **30**, 3461[2]) to be β-carotene. Milton Levy 10

Polysaccharides from tubercle bacilli and from tuberculin. Yosiharu Takeda and Tatuo Ota. *Z. physiol. Chem.* **262**, 171-7(1939).—Polysaccharides isolated from aq. exts. of human tubercle bacilli and from tuberculin were purified by repeated pptn. by EtOH and HOAc. The final white amorphous hygroscopic powders were compared. They differ only slightly in $[\alpha]_D$, 138° and 134°, in acid equiv. (972 and 1162), are both N- and practically P-free. On acid hydrolysis the bacillary carbohydrate gives 5.8% of mannose (as phenylhydrazone) and 60% of glucose (as benzylphenylhydrazone), whereas the tuberculin polysaccharide gives 23% of mannose and 56% of glucose. After these sugars are removed the hydrolyzates gave no reactions for pentose or methylpentose. The bacillary carbohydrate has a much greater biol. activity (precipitin and skin reaction) than the tuberculin carbohydrate. Milton Levy 11

Analysis of the tubercle bacillus and its natural products by immune, allergic and anaphylactic tests. H. J. Corper. *J. Infectious Diseases* **66**, 23-9(1940).—On a simple synthetic nonprotein medium max. bacillary growth of human tubercle bacilli occurs within 2 to 3 months, while tuberculoprotein liberation into the medium takes place mainly after max. growth is attained. The bacillary body sensitizes primarily to tuberculo-allergy and serves to immunize against virulent infection, while the natural filtrate contg. tuberculoprotein sensitizes to anaphylaxis and provokes anaphylactic shock and allergic intoxication but does not sensitize to allergy nor specifically immunize against virulent infection. Tuberculo-anaphylaxis, tuberculo-allergy, and tuberculo-immunity show distinctive characteristics which lead to the conclusion that they are sep. and apparently unrelated biol. phenomena. Julian H. Lewis 12

Effect of indole-3-acetic acid on multiplication of Esch. coli and E. typhosa. T. D. Beckwith and E. M. Geary. *J. Infectious Diseases* **66**, 78-9(1940).—Indole-3-acetic acid added to media in which are cultivated either *Esch. coli* or *E. typhosa* stimulates growth of the organisms. The organisms thus treated were from cultures within the period of logarithmic death. In greater concn., this salt inhibits growth. Julian H. Lewis 13

Additional observations on positive and negative chemotaxis. (Experiments with a myxomycete.) Dale Rex Coman. *Arch. Path.* **29**, 220-8(1940); cf. McCutcheon, C. and Dixon, *C. A.* **33**, 2960[2].—Chemotactic growth of *Physarum polycephalum* (slime mold) plasmodia is pos. to dextrose, neg. to HCl, H_2SO_4, AcOH and NaOH at concns. of 0.1 *M* or above, indifferent to sucrose and 0.1 *M* NaCl. J. McAfee 14

Studies on the nutrition of fungi. IV. Factors influencing the growth of some thiamine fungi. Leon H. Leonian and Virgil Greene Lilly. *Am. J. Botany* **27**, 18-26(1940); cf. *C. A.* **33**, 8231[3].—Fungi were grown in 250-ml. flasks on 25 ml. of nutrient soln. to which various test materials were added. Addn. of 0.05 p. p. m. of thiamine increased the yield of *Phycomyces blakesleeanus* (I) by 85% above the control. No increase followed addn. of 0.002 p. p. m. of thiamine. Addn. of 0.05% agar or an equiv. amt. of agar ash doubled the yield of I compared with the control, an indication that the nutritive effect of agar is in its inorg. components. Tests with various combinations of "rare" elements showed that 0.2 p. p. m. Zn nearly doubled the 15

growth of I, 0.02 p. p. m. of Cu, Ga, Mn, Mo and 0.2 p. p. m. of Fe, singly or in combination, had no effect. Addn. of 0.1% succinic acid increased the availability of ammonium and arginine N to I, but not the availability of nitrate N. Aspartic acid or NH_4NO_3 alone was a poor source of N but their combination enhanced N assimilation. The combination of succinic and aspartic acids, with or without NH_4 salts, was no better than either acid alone. This synergic effect occurred only in the presence of 0.02% or more of thiamine. At lower thiamine concns., growth was decreased by NH_4NO_3 and succinic acid compared with controls contg. the same amt. (0.2%) of aspartic acid. The optimum ratio was 0.2% NH_4NO_3 and 0.3% succinic acid. Tests with 0.02 *M* concns. of other acids showed citric to be toxic to *Pythium ascophallon* and *Pythiomorpha gonapodioides* but not to I or *Mucor ramannianus* and fumaric generally superior to glutamic, acetic, lactic, succinic and tartaric for increasing fungus yields. The N from asparagine was superior to the same quantity of N from aspartic acid when used singly, but in mixts. with agar, succinic acid or NH_4 salts, aspartic acid was superior. The synergic effect may be due to the presence of the free carboxyl group. In tests to det. the optimum ratio of dextrose, amino acids and thiamine for I and *Phytophthora erythroseptica* (II), it was found their requirements differed, also that II is extremely sensitive to thiamine. Amino acids appear to be utilized primarily as N sources in the presence of even small amts. of dextrose, and excess amino acids are not used as long as the sugar is kept near the min. The effectiveness of thiamine is closely related to the amt. of food present in the medium. Comparison of various amino acids as nutrients showed arginine was poorest and *dl*-alanine and asparagine were inferior to *l* aspartic acid, glutamic acid and glycine. The mixt. of 5 amino acids was best, suggesting synergism. Nelson McKaig, Jr

Toxicity of allyl isothiocyanate vapor to certain fungi. Dean E. Pryor, J. C. Walker and Mark A. Stahmann. *Am. J. Botany* **27**, 30-8(1940); cf. *Phytopathology* **29**, 641-3(1939). The toxicity of allyl isothiocyanate (I) vapor in equil. with its aq. soln. is dependent upon the concn., the total amt. present in the soln. and the plant species. *Gibberella saubinetti* was more sensitive than *Aspergillus niger*, *A. alliaceus* and *Colletotrichum circinans*. Growth was inhibited in a closed system when sufficient I was available in the soln. to maintain a vapor pressure above a certain limit. If the vapor concn. was below this limit either by low initial concn. or by absorption in the plants, inhibition did not occur, indicating the effect is not cumulative. Resistance increased with greater age of thalli. Spores were more variable in tolerance than mycelia of any age. The quantity of material required to produce a toxic concn. was less as the no. of spores was decreased. Nelson McKaig, Jr.

The oxidation-reduction potential requirements of a nonspore-forming, obligate anaerobe. Birgit Vennesland and Martin E. Hanke. *J. Bact.* **39**, 139-69(1940).—The course of potential and pH changes in mixed cultures of *Bacteroides vulgatus* (I) and *Alcaligenes faecalis* (II) in glucose nutrient broth and on a synthetic medium were studied, but attempts to det. a potential which would limit the growth of I were unsuccessful by this method. When the potentials of cultures of I in glucose nutrient broth were controlled by means of a mixed stream of N and O the pos. potential which just limited growth was +0.150 v. at pH 6.6. CO_2 was essential for the growth of I. Glucose brain broth of I showed a marked O consumption. The following hypothesis of anaerobic growth is presented: The potential in a culture indicates the state of a reversible oxidation reduction system; O affects the potential by oxidizing this system (directly or indirectly); the oxidizing action of O is counteracted by reducing substances in the culture medium which tend to reduce the reversible system, and which are derived from substrate mols. of high energy content which have been activated by enzymes (the dehydrogenases) of the cell; the enzyme system is active only in the reduced form; it is maintained in this form by the reducing action of the activated substrate mediated by the particular reversible system which dets. the electrode potential. 27 references. John T. Myers

Respiratory enzyme systems in symbiotic nitrogen fixation. II. The respiration of Rhizobium from legume nodules and laboratory cultures. D. W. Thorne and R. H. Burris. *J. Bact.* **39**, 187-96(1940); cf. *C. A.* **32**, 6684⁷. —Substrate studies indicated no const. differences between nodular and cultured rhizobia. The max. rate of respiration by a strain of *R. leguminosarum* from pea and vetch nodules and by a strain of *R. japonicum* from soybean nodules was reached at a lower O tension than that required for the same strain of cultured organisms. The reverse was true with a strain from cowpeas. No distinct differences were noted between nodular and cultured organisms in their reactions to a no. of inhibitors including: cyanide, ethylurethan, iodoacetate, pyrophosphate, malonate and maleate. Azide stimulated O uptake of vetch and pea nodular prepns. in glucose but inhibited the corresponding cultured strain of organisms. Fluoride greatly inhibited the respiration of a cultured strain from cowpeas with glucose as a substrate but strongly stimulated the corresponding nodular prepns. J. T. M.

The growth of human tubercle bacilli, H37, in synthetic medium with and without agar. W. F. Dreaj. *J. Bact.* **39**, 197-205(1940).—Agar definitely inhibited the growth of these bacilli when amts. greater than 0.1 to 0.25% were added to the synthetic medium. Smaller amts. had less inhibiting action. Growth occurs first at the bottom of a synthetic medium and later at the top. Colonies can be grown at different levels when 0.1% agar is present. This will aid in the study of probable accessory growth factors for tubercle bacilli. 10 references. John T. Myers

The bactericidal effect of sulfathiazole and sulfamethylthiazole on bacteria found in urinary infections. H. F. Helmholz. *Proc. Staff Meetings Mayo Clinic* **15**, 65-8 (1940). Sulfathiazole (I) and sulfamethylthiazole (II) were definitely bactericidal on urinary *Streptococcus faecalis* and *Staphylococcus aureus* when given in the usual dosage by mouth. The latter organism was more susceptible to I than the former; II was more active on *Streptococcus faecalis* than I. Five strains of *Proteus ammoniae* were readily killed off by I and II at a pH of about 5.5. Higher urinary concns. of the drugs were required to kill Gram-neg. bacilli of which *Pseudomonas aeruginosa* appeared to be the most resistant. Concns. of 150 mg./100 cc. free II, which was practically completely bactericidal for all other organisms, allowed luxuriant growth of 6 different strains of *Pseudomonas aeruginosa*, but I in the same concn. rapidly killed them. No parallelism was seen in the action of sulfanilamide and I or II on resistant and nonresistant strains of bacteria. J. Pinchack

The biological production of gluconic acid. K. R. Butlin and W. H. D. Wince. *J. Soc. Chem. Ind.* **58**, 363-5(1939). A method for the production of gluconic acid (I) from glucose is described in which *Bacterium suboxydans* is employed with intense aeration of the medium. Best results were obtained with an initial glucose concn. of 15%, but it was found that glucose could be added during fermentation to make the total glucose up to 30-35%. Almost quant. conversion into I or its Ca salt was obtained if the pH (6.5) was controlled to allow good growth of the organism, and subsequently not allowed to fall below pH 3.5. The best medium for the growth of *Bacterium suboxydans* consisted of 0.5% Difco yeast and 0.5% KH_2PO_4 in H_2O. I was obtained as Ca gluconate by adding the required amt. of chalk for neutralization and warming. The Ca gluconate crystd. readily on evapn. and was purified by recrystn. from hot H_2O. The course of the fermentation was followed by the detn. of the glucose content by the titration method of Schaffer, Hartman and Somogyi (cf. Peters and Van Slyke, *Quant. Clinical Chemistry* p. 465; *C. A.* **26**, 3275). Maurice M. Rath

The formation of acetol from α,β-propylene glycol. K. R. Butlin and W. H. D. Wince. *J. Soc. Chem. Ind.* **58**, 365-6(1939).—Concns. of α,β-propylene glycol (I) up to 15% can be rapidly and almost quantitatively converted into acetol (II) by means of the acetic acid organism

Bacterium suboxydans. Expts. showed that for this biol. oxidation the best nutrient medium is one contg. an aq. soln. of 0.5% Difco yeast ext., 0.5% KH_2PO_4, and 0.5% glycerol or glucose. I was used in a concn. of 5–10%. When this medium was intensely aerated at 30° almost quant. production of II was obtained. Best results were obtained when inoculation of the fermentation liquid was carried out at pH 6.5, which is favorable to the growth of the organism, and the pH allowed to fall slowly to 4.5. Aeration for 18 hrs. effected an almost quant. conversion into II when a 5% soln. was used; the same resulted with a 10% soln. in less than 2 days while if a further 5% of I was added to the latter during fermentation the total 15 was converted into II in less than 3 days. The aeration was carried out by blowing air through a block of sandstone immersed in the liquid. The method of extn. of II from the fermentation liquid and the method of analyzing the amt. of II were based on those of Perkin (cf. *J. Chem. Soc.* **59**, 787(1891)). Maurice M. Rath

Studies on the metabolism and on the proteolytic enzymes of the strict anaerobes. J. C. Hoogerheide and L. Weil. *J. Franklin Inst.* **228**, 519-20(1939).—Proteins utilized by spore-forming anaerobes are broken down by a proteinase of pH optimum 7.0 which can be activated markedly by —SH compds. + traces of heavy metals. Proteinase from bacteria cultivated in the usual media readily attacked all protein substrates tested. Repeated transplants onto casein or gelatin media gave specific casein and gelatin proteinases. On cultivating casein-trained bacteria on gelatin, or gelatin-trained bacteria on casein, an enzyme attacking both proteins was produced. When the bacteria were cultivated in the presence of glucose the pH of the medium fell from 7.4 to 5.7 during the growth, and the proteinase obtained had a pH optimum of 6.0. Once amino acids are available they are used by the bacteria in energy-yielding processes such as fermentation of amino acids and Stickland reactions (between H donors and H acceptors). When the bacteria were cultivated at lower pH, the pH optima of several dehydrogenases became more acid. With glucose in the medium, bacteria were obtained which readily utilized glucose and its metabolites EtOH and H_2. The enzymic activity of the bacteria reflected the particular phase of growth, changing with age and with the compn. of the culture medium. The products of reactions between amino acids and gaseous H_2 brought about by suspensions of *Clostridium sporogenes* are given. Cf. *C. A.* **31**, 7910[1]; **32**, 209[2], 5437[6], 9160[7]; **33**, 2158[5], 2174[8], 2175[1], 8236[6]. Edward B. Sanigar

Rhythmic clumping of Proteus vulgaris. H. Knöll. *Kolloid-Z.* **89**, 135-44(1939).—The rhythmic banding of the growth of *P. vulgaris* is a function of the medium on which the organism is grown. The richer the medium, the less is the tendency for bands to form. Felix Saunders

Ring formation during bacterial growth. Hans Schmidt. *Kolloid-Z.* **89**, 145(1939).—Ring formation by *Proteus vulgaris* is a function of the kind of sugar used in the agar. Sucrose, lactose and maltose produce very marked rings, but with dextrose and levulose the ring formation is much less definite. Felix Saunders

Bacteriostatic action of sulfanilamide under anaerobic conditions. R. H. Broh-Kahn. *Science* **90**, 543-4(1939). —Sulfanilamide produces, under certain circumstances, marked bacteriostasis in cultures of *Esch. coli*. Thus, in ordinary meat broth, bacteriostasis is observed under aerobic but not under anaerobic conditions, but in broth contg. 1% glucose, sulfanilamide produces little effect. This protective action of glucose is not due to its reducing properties since both cysteine and ascorbic acid fail to protect against the sulfanilamide bacteriostasis. When sulfanilamide is added to cultures growing aerobically in a synthetic-lactate or a lactate-nitrate medium, very little bacteriostasis is evident. However, anaerobic cultures in the latter medium are markedly inhibited by the action of sulfanilamide, an example of a case in which sulfanilamide is bacteriostatic in anaerobic but not in aerobic environment. Bacteriostasis produced by sulfanilamide and allied compds. cannot be attributed to any general, non-specific mechanism. Felix Saunders

Effect of nicotinamide on respiration of dysentery bacilli. Albert Dorfman, Stewart A. Koser and Felix Saunders. *Science* **90**, 544-5(1939).—Dysentery bacilli (Strain D76) were grown 24 hrs. in a synthetic medium contg. 0.005 γ/cc. of nicotinamide. The cells were collected in the centrifuge, suspended in 0.05 *M* phosphate buffer and again centrifuged. A suspension of these cells was placed in Thunberg tubes contg. methylene blue and glucose. The time of reduction of the methylene blue is greatly increased not only by the addn. of cozymase but also by the addn. of nicotinamide or nicotinic acid. When the amt. of nicotinamide in the medium on which the cells are grown is increased to 0.020 γ, the addn. of nicotinamide, nicotinic acid or cozymase to the Thunberg tube does not decrease the time of reduction of methylene blue beyond that of the controls. Nicotinamide, nicotinic acid or cozymase did not reduce methylene blue in the absence of cells. The same stimulation of respiration by nicotinamide, etc., was found when O uptake was measured by the direct Warburg method. Felix Saunders

Vitamin B_6 as an accessory growth factor for Staphylococcus albus. S. P. Vilter and T. D. Spies. *Science* **91**, 200-1(1940).—Vitamin B_6 in amts. of 0.3-1.2 γ/cc. stimulates growth and acid production of *Staph. albus* when nicotinic acid and thiamine are present. F. Saunders

Anaerobic production of flavin in Eremothecium ashbyii. Anne Raffy. *Compt rend.* **209**, 900-2(1939).—The organisms produce flavin anaerobically. Walter H. Seegers

Buffering fermentation media. A. R. Kendall. *Proc. S. Dakota Acad. Sci.* **19**, 32-43(1939).—A brief review of buffer systems is given. A medium for *Aerobacter pectinovorum* fermentation, with an optimum initial pH of 6.0 and an av. mol. buffer value of 0.537 in the pH range 5.2-6.0, has the following compn.: $MgSO_4$ 0.100 g., NH_4Cl 0.250 g., sucrose 8.000 g., succinic acid 1.180 g., NaOH 0.725 g. and water up to 100 cc. W. H. S.

The biochemistry of microörganisms. VIII. The splitting of tyrosine by various bacteria. W. Grimmer and B. Wauschkuhn. *Milchw. Forsch.* **20**, 110-30(1939); cf. *C. A.* **30**, 6781[8].—*Oidium lactis* converts tyrosine into (*p*-hydroxyphenyl)lactic acid and tyrosol ((*p*-hydroxyphenyl)ethanol) (I); *Bacterium mesentericus* converts it into I and tyramine ((*p*-hydroxyphenyl)ethylamine) (II), and *Bacterium putrificus* to (*p*-hydroxyphenyl)-propionic acid (III); micrococci from Tilsiter cheese to II; *Bacillus coli* in alk. medium, to (*p*-hydroxyphenyl)-acetic acid (IV) and I, *Streptococcus casei* from Tilsiter cheese to III; *Bacillus lactis aerogenes* to I and IV. E. O. Whittier

Blowing of cheese [gas production by coli-aerogenes bacteria] (Schwarz, *et al.*) **12**. Production of lactic acid from substances other than sugar by *Lactobacillus casei* (Thiel) **12**.

D—BOTANY

THOMAS G. PHILLIPS

Chemical constituents observed in cellulose formation. T. Tadokoro and S. Kobayasi. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 324(1939).—In agreement with Voss, Bauer and Phrsolike (*C. A.* **32**, 8770[9]), a const. ratio was found for the cellulose and insol. xylan contents ($C_6H_{10}O_5$:$C_5H_8O_4$ = 3.1) of red beech, irrespective of the origin and age of the tree. In expts. on pine and cedar trees 5 to 15 yrs. old, an increase of α-cellulose and of lignin contents, as well as a decrease of alc.-benzene extractible materials, acetyl-group, pentosan and mannan contents was noted with the declining years of these trees. II. *Ibid.* 375.—From an examn. of the buds and terminal portions of pine and cedar trees 4–7 yrs. old, it was thought that the principal sources of α-cellulose were alc.-benzene extractible materials and mannan of the bud. George Ayers

Chemical analysis as an aid to botanical classification.

R. H. F. Manske. *Can. Chem. Process Inds.* **23**, 199–200, 210(1939). C. L. B.

The assimilation of carbon dioxide by green plants. I. The problems of assimilation. W. Noddack. *Z. physik. Chem.* **A185**, 207–21(1939).—A general review of the chem., kinetic and photochem. aspects of photosynthesis, with suggestions as to problems for further exptl. investigation. **II. Assimilation and light intensity.** W. Noddack and H. J. Eichhoff. *Ibid.* 222–37(1939).—A *monochromatic illuminator* giving intensities up to 42,000 lux is described. This app. gives, at 5000 A., 95% of the energy in a region 70 A. wide; at 8000 A. the corresponding width is 200 A. Suspensions of unicellular green algae (*Chlorella pyrenoidosa*) contg. 2.02×10^6 cells per cc. were illuminated with white light and the rate of O evolution at 20° was detd. as a function of the light intensity. Similar expts. were performed with red (6500 A.) and green (5675 A.) light of varying intensities and with algae suspensions of different cell-contens. The dil. suspensions illuminated with either white or red light approached their max. rate of assimilation at much lower intensities than did the dense suspensions. Below approx. 17,000 lux white light gives a higher fraction of the max. rate for a given suspension than does red light of corresponding intensity; above this value the situation is reversed. Green light gives a very low rate of assimilation in every case. T. H. Dunkelberger

Influence of certain hormone-like substances on the rooting of hardwood blueberry cuttings. Stanley Johnston. *Mich. Agr. Expt. Sta., Quart. Bull.* **21**, 255–8 (1939).—The com. prepns., Auxilin and Hormodin A, when used at several concns were ineffective in stimulating root formation in blueberry cuttings. C. R. F.

Starch reserves in the roots of pastured alfalfa when grown alone and in mixtures. H. C. Rather and C. M. Harrison. *Mich. Agr. Expt. Sta., Quart. Bull.* **21**, 281–91(1939).—When grown alone, alfalfa stored starch more readily in the roots than when grown in a mixt. with grass. Starch reserves in the alfalfa roots previous to killing frosts were necessary to prevent carbohydrate starvation of the plants and winter-killing. The roots were lowest in starch during the period of most active growth in the spring, and starch also becomes depleted with close grazing or cutting. C. R. Fellers

Acid tolerance of the highbush blueberry. T. A. Merrill *Mich. Agr. Expt. Sta., Quart. Bull.* **22**, 112–16(1939). The min. pH limit for *Vaccinium corymbosum* is 3.2. Symptoms assocd. with too great acidity are leaf scorch beginning at the margins and, finally, death to the plants. Of the several treatments, applications of lime sufficient to raise the pH to 3.4–3.8 prevented leaf scorch and resulted in normal growth. C. R. Fellers

Effect of soil moisture on acid content of tomatoes. Preliminary report. F. A. Lee and C. B. Sayre. *Food Research* **5**, 69–72(1940).—Immature tomato fruits are high in acidity. As the maturation process develops, the acidity decreases, and finally increases in the ripe fruit. Varieties vary in their titratable acidity. Percentage acidities, calcd. on a dry-wt. basis, follow: King Humbert 3.76; John Baer 5.32; Supreme Marglobe 6.22; and Golden Queen (yellow variety) 5.32. C. R. Fellers

Influence of variety, season and green manures on the composition of wheats. J. E. Greaves, Aaron F. Bracken and C. T. Hirst. *J. Nutrition* **19**, 179–86(1940); cf. *C. A.* **31**, 7466[2].—Spring wheat grown on low-moisture soils contained higher percentages of ash, Ca, Mg, K, Fe, P and S than winter wheat grown on the same soil. There were marked variations in Ca content in several varieties of wheat. The use of green manures materially increased the P content, probably because of its effect in stimulating bacteriol. activities which in turn increased the soil stores of available plant food. C. R. Fellers

Growth of isolated cells from Lupinus albus seedling tips. R. Gautheret. *Compt. rend. soc. biol.* **132**, 351–2 (1939).—In a suitable medium isolated cells from the growth zone increase in size but do not divide. 3-Indoleacetic acid in 10^{-6} diln. stimulates this growth, but only when a fragment of live lupine root is present in the medium. This indicates that the root liberates a substance into the medium which promotes the action of the heteroauxin. L. E. Gilson

The dependence of the ascorbic acid content of plants on internal and external factors. Heinz G. Moldtmann. *Planta* **30**, 297–342(1939).—Of the phanerogams, certain monocots (*Iris squalens, I. sambucina, Gladiolus communis*) have especially high ascorbic acid (I) contents. Plants without chlorophyll (*Lathraea, Orobanche* and fertile shoots of *Equisetum arvense*) contain no I. I is formed in germinating seeds even in darkness; the content rises considerably during the first days of germination, but later falls until chlorophyll appears. Subterranean plant parts contain little or no I; it increases up the stem to the mesophyll of the leaves, but M. found it higher in white or yellow petals than in leaves. Fruits rich in carotenoids increased in I during ripening, especially after the ripe colors appeared. A max. in I appeared during the day and a min. at night. Prolonged cloudiness reduced it. The max. in the leaves of *Fagus silvatica* came in July; in the needles of *Taxus baccata* in March. Ultraviolet irradiation had no effect. The I content rose with the intensity of CO_2 assimilation; it was unaffected by that of the respiration. The I content rose in each species as the glucose content increased, but not when this was accomplished by ringing. Some colorless leaf sectors had more, some less, I than normal green sectors. Detns. of I were by the method of Tillmans. Thirty-five references. E. L. Green

The use of the gas-metabolism recorder in carbon dioxide assimilation. Heinrich Auldemgarten. *Planta* **30**, 342–52(1939).—The app. (*C. A.* **33**, 7343[9]) is improved and in expts. with *Stichococcus bacillaris* it showed that the shape of the assimilation curve was independent of the supply of org. nutrients. The kind of mineral nutrients supplied had a considerable effect (comparison between Eiler's, Kolkwitz' and peptone glucose solns.). E. L. Green

Retardation of carbon dioxide assimilation by light and temperature. M. G. Stalfelt. *Planta* **30**, 384–421(1939). —The daily course of photosynthesis in oats under field conditions and in lichens under const. conditions was studied. Light intensities and temps. above certain limits reduced photosynthesis. This reduction was expressed as relative reduction, i. e., the comparison with the mean daily fall of photosynthesis under optimum conditions. It was found to be proportional to the light intensity and reversible if effected by light, but irreversible (in the dark) and independent of the light if by heat. The effect of heat is believed to be generally destructive, while that of light is photochem. and specific. Extensive bibliography. E. L. Green

Formation and distribution of resin in the larch (Larix europaea). Paul Jaccard, A. Bourquin and G. H. Bornand. *Eidgenoss. Materialprüfungs- u. Versuchsanstalt Ind., Bauw. Gewerbe, Zurich, Ber.* No. **97**, 18 pp (1939) (in French).—A morphological study reported under the following headings: anatomical structure and formation of resinous canals, distribution of resinous canals in the wood and pathological secretion of the resin, together with 11 sketches of microscopical structure. Numerical data for the distribution of resinous canals in *L. europaea* from 4 localities are tabulated. Data are also presented to show the relation between sp. gr., proportion of fiber wall and resistance to compression for larch and 14 other woods. L. Wilson Greene

The chemical composition of the leaves of Morus alba. S. Ya. Demyanovskiĭ. *Uchenye Zapiski Fakul'teta Estestvoznaniya, Moskov. Gosudarst. Pedagogicheskiĭ Inst., Lab. Org. i Biol. Khim.* **1938**, No. 3, 55–88; *Khim. Referat. Zhur.* **2**, No. 5, 51(1939).—For leaves collected in Mirgorod (May-August) and in Tashkent (April-June) are given, in relation to their degree of ripeness, shape of the tree and the character of irrigation, the contents of water, ash, P, total and protein N, sol. carbohydrates, cellulose, fat, titer value and active acidity. W. R. H.

The absorption of nutritive elements by the lupines. A. Wojtysiak. *Polish Agr. Forest Ann.* **39**, 133–88

(in French, 188–90)(1937).—*L. angustifolius* var. *roseus* subvar. *praecox pulaviensis* (I), *L. angustifolius* var. *coeruleus* (II), *L. luteus* (III) and *L. albus* (IV) were studied. Samples of 100 plants were taken every 5–10 days during the period of vegetation. During the pre-blossom and blossom stages III and IV showed, resp., the greatest and least increase in abs. dry wt. In the pre-blossom stage III showed the greatest uptake in N, P_2O_5, K_2O and CaO, IV the least. In the blossom period III took up more N, P_2O_5 and CaO than the other varieties; IV assimilated more K_2O. Conversely in the last or post-blossom stage IV showed greatest increase in all the nutritive factors studied. The P_2O_5:N ratio for the plants was as follows: in the pre-bloom period greatest for I and narrow for II; in the bloom stage greatest for IV and in the post-bloom period greatest for III and IV. As a consequence of this study W. points out that rational use of these plants as fodder or fertilizer depends on knowledge of the nutritional stage of a given species. C. T. J.

The role of leaf water-content, soil moisture and plant age on transpiration of crop plants. B. N. Singh and R. B. Singh. *J. Indian Botan. Soc.* **16**, 63–80(1937).—Expts. were made on cotton, rice and tobacco. For a given crop there was no appreciable difference in the daily rates of transpiration at a particular stage of development (seedling, vegetative or reproductive) despite the change in the evapg. power of the atm. The av. daily rate of transpiration for a particular crop varied in accordance with the metabolic need of the plant at different developmental stages in the life cycle of each crop. There was a high hourly rate of transpiration during the seedling stage and the stage prior to the initiation of reproductive primordia. Different crops seemed to have different physiol. resisting power for transpiration under similar conditions of environment and to possess varying daily rates of transpiration per unit area of leaf even under similar conditions of atm. variables. The greater the percentage of water in the leaf during the active period of growth, the greater was the difference between the max. and min. of the water content during the day. With the advent of age the water content of leaves during the day approximated to an av. min. from hr. to hr. on a clear day. The view is held that the water content of leaves represents the balance between absorption on the one hand and transpiration on the other. If transpiration is in advance of absorption, a deficit in the water content should follow, but when the reverse is the case the water content should increase. There were indications that the rate of transpiration is directly proportional to the rate of supply of water to the plant. K. D. Jacob

Unequal absorption of ions and their rate and order of entry from a three-salt nutrient. B. N. Singh and S. C. Chakravarti. *J. Indian Botan. Soc.* **16**, 81–93(1937).—Wheat, paddy and flax were grown in Shive's 3-salt culture soln. and the absorption of component ions of the different salts ($Ca(NO_3)_2$, $MgSO_4$ and K phosphate) constituting the medium was studied at successive stages of growth of the plants. Unequal absorption of ions was not restricted to single-salt solns. and to shorter durations of growth alone, but occurred with balanced solns. and for the whole, or a part of the life cycle of the plants. In the case of plants growing during long-range experimentation, the H and OH ions seemed to be mainly responsible for unequal absorption. During the early stages of growth (1st 2 weeks or less) the pH of the nutrient solns. decreased to min. values, then increased to max. values (considerably above that of the original soln.) at 6 weeks and subsequently decreased rapidly. At all stages of growth the nutrient solns. supporting paddy showed higher pH values than did those supporting flax. In the majority of cases K and N were absorbed in greater proportion, but the absorption of the other ions showed no regularity and seemed to be detd. by the specific requirements of the plants at successive stages of growth. The rate of entry of the ions decreased as the plants advanced in age during the vegetative period, but with the onset of the reproductive phase the rate increased to fall again toward the close of the life cycle. K. D. Jacob

The physiological and chemical changes accompanying viviparous germination in mango. B. N. Singh and B. N. Lal. *J. Indian Botan. Soc.* **16**, 129–36(1937).—A local variety of *Mangifera indica* was studied. As compared to that of normal fruit under controlled conditions of environment during germination, the mesocarp of viviparous fruit is characterized by lower respiration and pH values, smaller percentages of nonreducing sugars, starch, total N and moisture and a slightly higher percentage of reducing sugars. In contrast to the conditions existing in the normal fruit, the changes inside the seed of the viviparous fruit are characterized by higher rate of respiration, more so in the plumule and radicle than in the cotyledons; higher moisture content; lower pH, especially in the plumule and radicle; lower percentages of starch and non-reducing sugars; higher percentages of reducing sugars, especially in the plumule and radicle; and lower percentages of N in the cotyledons but higher percentages in the plumule and radicle. The general tendency seems to be toward a breakdown of reserve substances in the mesocarp of viviparous fruit, which usually does not occur in normal fruit. As compared to that of normal fruit, germination of viviparous fruit is accompanied by a much greater breakdown of starch in the cotyledons.

K. D. Jacob

The respiration of Eugenia jambolana leaves with respect to their sugar, acid and catalase contents. N. K. Chatterji. *J. Indian Botan. Soc.* **16**, 245–58(1937).—With advancing age the pH values of freshly detached leaves increased more or less regularly from 4.62 for those 2 days old to 7.10 for those 6 months or more of age; the catalase activity (expressed in terms of O_2 evolved from H_2O_2 per 10 g. leaves) decreased from 30 cc. to 18.0–18.5 cc; the monosaccharide content decreased from 1.43 to 0.53–0.63% of the fresh wt.; and the total acid content (expressed in terms of 0.01 *N* oxalic acid) decreased from 31.1 to 10.3–10.4 cc. Likewise, the total CO_2 output in 25 hrs. decreased from 8.45 to 4.13–4.95 cc. per g. fresh wt. With leaves of all ages the rates of respiration reached max. values in 20–25 hrs. after they were removed from the plants and then decreased with time. In general, there seemed to be a close relationship between the total CO_2 output per 25 hrs. and the initial glucose content of the leaves. The O_2 intake of the leaves decreased with advancing maturity and also with increase in the length of time that the detached leaves were kept under the exptl. conditions. Continuous conversion of sugars into oil globules occurs in the old yellow leaves and oxidation of the C compds. to CO_2 is effected in part by the O liberated during formation of the oil.

K. D. Jacob

Wounding of the leaves of Anacardium occidentale Linn. at different stages of their development and its effect on respiration. A. B. Saran. *J. Indian Botan. Soc.* **17**, 1–4(1938).—The respiration rate of young leaves of *A. occidentale* is higher than that of adult ones, but the rate becomes approx. const. at a lower level at 30–40 days of age. Such young leaves do not show any aftereffect when they are wounded, whereas a similar treatment of the older leaves enhances their respiratory activity considerably during the 1st 2–4 hrs. after wounding.

K. D. Jacob

Isoelectric point of the proteins of the tissues of the cotton plant in relation to the pH of the cell sap. R. H. Dastur and S. V. Mensinkai. *J. Indian Botan. Soc.* **17**, 149–60(1938).—The pH values of the cell sap of the tissues of the roots, stems, vegetative branches, fruiting branches and bolls fluctuate more or less irregularly during the life of the plant, but they reach max. values during the intense flowering period and then decrease to an approx. uniform min. value during the last stages of senescence. The pH of the cell sap of the leaves of the vegetative branches increases more or less steadily with a marked increase to nearly 7 during the period of intense flowering and a rapid decrease in the senescent stages. The apparent isoelec. points of the proteins of the roots, stems and leaves are at pH values below those of the corresponding tissue saps throughout the life of the plant. The proteins

are positively charged and the charge changes as the pH value of the sap changes during growth. At the termination of the plant's activity the proteins reach an isoelec. point which is very close to the pH (5.5) of the plant sap at that stage. K. D. Jacob

Respiration of amphibious plants. I. Scirpus articulatus Linn. B. Samantarai. *J. Indian Botan. Soc.* **17**, 195-204(1938).—The respiratory activity increases with increase of O_2 concn. in the water in which the plant respires and scapes that have low respiratory values under water have higher values when they become aerial. The respiration of the hollow submerged scapes is greater than that of submerged plants before scapes are formed, owing to the greater O_2 content of the hollow scapes. On the other hand, air-free scapes (scapes injected with water) show lower respiration than normal scapes. K. D. J.

The growth of rice seedlings in salt solutions of different hydrogen-ion concentrations. R. H. Dastur and Winifred John. *J. Indian Botan. Soc.* **17**, 255-68(1938). —The greatest growth was obtained in salt solns. having pH values of 6.0-7.0. pH values below 6 were detrimental to the growth of the seedlings and little or no increase in dry wt. was obtained when the salt solns. had pH values below 5. Culture with $FePO_4$ was superior to culture with $FeSO_4$ and to culture without Fe, but there was no difference between culture with $FeSO_4$ and culture without Fe. Culture with KNO_3 as the source of N was superior to culture with $(NH_4)_2SO_4$. Among the single-salt solns. $(NH_4)_2SO_4$ and NH_4 phosphate were superior to KNO_3. Growth was poor in solns. of NH_4Cl, $NaNO_3$ or $Mg(NO_3)_2$ In the 2-salt solns. those that contained NH_4 phosphate were better than other combinations. The best growth was obtained in the ordinary culture soln. (Tottingham's modification of Knops' culture). K. D. Jacob

The rate of respiration and respiratory quotient of starved leaves of Aralia sp. before and after a course in nitrogen. A. B. Saran. *J. Indian Botan. Soc.* **17**, 287-91 (1938).—There was no marked seasonal variation in the initial rate of respiration of leaves of *Aralia* sp. When N_2 was substituted for air at or beyond 44 hrs. of starvation (detached leaves) the rate of respiration was temporarily enhanced, but the same treatment given at an earlier stage (22 hrs. of starvation) caused a lowering of the respiration rate. In both cases, when air was again admitted the rate of respiration increased temporarily. After a course in N_2 the respiratory ratio dropped to a low value of 0.70-0.75 for a period of approx. 4 hrs., after which it returned to its normal value (unity). K. D. Jacob

A laboratory experience in testing wax mixtures for use in plant propagation. E. M. Shelton. *Northern Nut Growers Assoc., Rept. Ann. Meeting* **28**, 72-5(1937).— A wax to be used for coating nursery stock must prevent evapn. of water, inhibit mold growth and be nontoxic to the coated plant. The effectiveness of waxes in preventing evapn. of water and inhibiting mold growth can be detd. by the use of gelatin candles (composed of water 100, locust bean ext. 1, ground sizing glue 50 and sucrose 1.5 parts). Four candles are dipped in the wax to be tested. Two are scored with a safety razor blade just deeply enough to cut through the wax, to simulate breakage of the covering which might occur in practice. The candles are weighed, hung in dry air and reweighed at intervals. For the molding test, four candles are prepd. in a similar manner, suspended in a moisture-satd. atm. and observed for mold growth. For the toxicity test, dormant forsythia or white ash cuttings are dipped in the wax, leaving uncoated about 10 cm. at the base of each cutting, and are placed in jars with water covering the uncoated ends. The cuttings are observed for toxic symptoms over a period of several weeks. K. D. Jacob

Use of growth substances in bench grafting of walnuts and hickories (a progress report). C. C. Lounsberry. *Northern Nut Growers Assoc., Rept. Ann. Meeting* **29**, 63(1938).—A paste contg. 1 g. indoleacetic acid per 200 g. lanolin was spread thinly on the top of the scion and around the union of the graft and at the lower end of the seedling root where it was cut off. Satisfactory roots came from the lower end of the scion, as well as on the seedling-root grafted varieties of English walnut, Japanese butternut, hican, pecan and shagbark hickory. Similar results were obtained on scions that were immersed for 24 hrs. to a depth of 1 in. in a soln. contg. 20 units of indolebutyric acid and were then treated, as before, with a paste of lanolin and indolebutyric acid. Although no roots came from the scions of black walnut, roots came from both top and bottom of the seedling root used as stock. Indolebutyric acid appeared to be more rapid in its action than indoleacetic acid, but the lanolin paste of the latter seemed to last longer in an effective form. K. D. Jacob

Delinting and germination of cotton seeds as affected by $ZnCl_2.2HCl$ treatment. B. N. Singh, R. S. Choudhri and S. L. Kapoor. *Indian J. Agr. Sci.* **9**, 731-9(1939).— To est. the degree of delinting and germination effects in Indian and American cotton varieties following seed immersion, for various durations, in $ZnCl_2.2HCl$, expts. were conducted in sand culture and the inquiry enlarged so as to include also the detn. of seedling growth. The germination process was greatly activated by $ZnCl_2.2HCl$ treatment of seeds, doses of 5-15 min. duration being very satisfactory. Such treatments initiated early start, higher percentage and early completion of germination. Shorter or longer treatments induced gradual depletion in the germinating vigor of seeds from the optimal value, though in the majority of cases germination was still superior to the controls. The permanency of the effects of these treatments was well evidenced by the resulting seedlings which were taller and accumulated greater dry matter than their controls. 8 references. A. H. Krappe

The influence of various growth factors on the growth of green plants. David M. Bonner and James Bonner. *Am. J. Botany* **27**, 38-42(1940); cf. *C. A.* **33**, 9370⁸.— Adenine at below 1 γ per l. of nutrient soln. in sand cultures increased the dry wt. of *Cosmos sulphureus* 3-fold. Uric acid at 10 γ per l. increased leaf growth of *Cosmos* and mustard in a manner similar to adenine. Nicotinic acid at 50 γ per l. stimulated growth, particularly in the roots of *Cosmos* and cocklebur (*Xanthium pennsylvanicum*) and vitamin B_6 increased the dry wt., particularly of the roots, of mustard, cotton and *Cosmos*. Growth of *Cosmos*, mustard and cocklebur were stimulated in lesser degree by 2 γ of estrone per l. The effects of adenine (leaf growth factor) and vitamin B_1 (root growth factor) were not additive, possibly because treatment with adenine stimulates natural production of vitamin B_1 in the plant. Wheat and tomato plants did not respond to additions of vitamins B_1 or B_6, estrone, adenine, or their combinations. Nelson McKaig, Jr.

Influence of the size of the inoculum on the growth of Chlorella vulgaris in freshly prepared culture medium. Robertson Pratt. *Am. J. Botany* **27**, 52-6(1940).—The multiplication of *Chlorella vulgaris* furnished with 5% CO_2 and 95% air in the nutrient soln. conformed to the equation of an autocatalyzed unimolecular reaction during the greater portion of the growth period but was inadequate at early growth stages. The discrepancy increased with dilu. It is suggested that a growth-inhibiting factor, the amt. of which varies directly with the no. of cells, is released into the culture. When there are few cells, this toxic factor is dil. and multiplication is less retarded than in the presence of large nos. of cells and consequently greater concn. of the growth-retarding substance. Nelson McKaig, Jr.

The vitamins in plant physiology. Michelina Palazzo. *Ann. ist. super. agrar. Portici* **8**, 48-68(1936-37).—A review. A. R. Merz

Organic complexes of high molecular weight and their variation in plant cells and tissues. W. W. Lepeschkin. *Ber. deut. botan. Ges.* **57**, General Meeting No., 91-9 (1939); cf. *C. A.* **33**, 997⁶.—The longitudinal scattering of infrared rays produced by plant tissues and yeast suspensions is far greater than that produced by protein solns. It is concluded that this is caused by the presence of vitaids of high mol. wt. Killing the tissues with resultant breaking up of the vitaids reduces the amt. of infrared scattering. Young active tissues have a greater effect

initially than older material and killing such tissues results in a greater decrease than that ensuing from the killing of older tissues. Lawrence P. Miller

Notes on the effects of alcohol and acetic acid on spermatogenesis in Isoetes japonica Al. Br. Akira Yuasa. *Japan. J. Botany* **8**, 297–301(1938).—Spermatogenesis was accelerated by low concns. of C_2H_5OH and retarded by AcOH. Lawrence P. Miller

The developmental change of quantities of chlorophyll and carotenoid in the leaves of rice plants, barley and wheat. Hideo Nagasima. *Japan. J. Botany* **9**, 277–96 (1938).—The content of carotenoid pigments showed 2 maxima, one at the season of most active growth and the other during the reproductive phase. The quantity of chlorophyll showed similar variation with the reality of the 2nd max. somewhat uncertain. L. P. M

Studies on the formation of ascorbic acid in plants. I. The influence of light on the ascorbic acid contents of various etiolated seedlings. Tomota Sugawara. *Japan. J. Botany* **10**, 141–50(1939).—Seedlings germinated in the dark contain some ascorbic acid, but the amt. is increased if light is furnished. Lawrence P. Miller

Some associated factors in the development of watercore. C. P. Harley. *Proc. Am. Soc. Hort. Sci.* **36**, 435–9(1939). —Factors intimately assocd. with carbohydrate metabolism in the leaf seem to be instrumental in predisposing apples to watercore. If sufficient carbohydrate has been synthesized and transported to the fruit, it is probably rendered subject to the action of high temp., subsequent starch hydrolysis, and resultant watercore. L. P. M.

Symptoms of boron deficiency in the rose. O. W. Davidson and H. M. Biekart. *Proc. Am. Soc. Hort. Sci.* **36**, 841–4(1939).—Preliminary results (microchem. tests) showed increased amts. of starch and tannin in rose plants deficient in B. Lawrence P. Miller

Further investigations on the growth substance of potatoes suffering from disintegration disease. Hilde Lucas. *Phytopath. Z.* **12**, 334–50(1939).—A continuation of the work reported by Jahnel (*C. A.* **33**, 7346[1]) With the diffusion method, no tangible difference was observed in the distribution of growth substance between diseased and sound potato plants in the beginning of development. Only in later development could be clearly detected in the diseased plants a smaller amt. than was present in the healthy ones. Diseased young daughter buds do not have a growth-substance deficit until they have attained a considerable development. Max. growth-substance content was found in the base, middle and tip of the stem. The distribution is uniform throughout the buds. Polar conduction of growth substance in the buds is only slightly greater than the reverse. The leaf shaft of diseased plants exhibits graduated heteroauxin concn. less strongly than do the healthy ones. Extn. methods using ether, chloroform or alc. are, at the present time, not serviceable for potatoes. Merritt N. Pope

Vernalization and the growth-phase concept. H. H. McKinney. *Botan. Rev.* **6**, 25–47(1940). —A review. Felix Saunders

Problem of Golgi material in plant cells. Laura J. Nahm. *Botan. Rev.* **6**, 49–72(1940).—A review. Felix Saunders

Photosynthesis with radio-carbon. S. Ruben, M. D. Kamen, W. Z. Hassid and D. C. DeVault. *Science* **90**, 570–1(1939).—The rate of photosynthesis by *Chlorella pyrenoidosa* with radioactive CO_2 (C^*O_2) was detd. by the Warburg manometer method and by radioactive technique. C^*O_2 reduction is markedly affected by HCN and phenylurethan. The light and dark reduction is enormously decreased by 10^{-2}–10^{-3} *M* HCN. At these concns. of HCN photosynthesis is strongly inhibited but respiration is unchanged. *Chlorella* cells reversibly reduce C^*O_2 in the dark; 85–95% of the dark-reduced C* can be extd. by boiling 1 min. with water; 70–80% of the C* in this ext. is pptd. by Ba or Pb in 80% EtOH. The Ba ppt. from the light-reduction ext. contained a smaller fraction of the C*. Prolonged boiling with *N* HCl does not decrease the Ba-insol. radioactivity. The presence of a carboxyl group in the radioactive mols. is indicated. The water-sol. ext. from *Chlorella* exposed to C^*O_2 for short times in light or dark has a mol. wt. of at least 200, probably much greater. The reversible uptake of CO_2 in the dark may be written $CO_2 + RH \rightleftarrows RCO_2H$. The energetics of the reaction are discussed. Felix Saunders

Production and utilization of alcohol by plant tissues. C. A. Ludwig, Franklin E. Allison, Sam R. Hoover and Francis W. Minor. *Science* **91**, 170–1(1940).—Under anaerobic conditions alc. and CO_2 are produced by both nodules and roots in proportions which indicate that alc. is the chief unoxidized product. Under aerobic conditions increasing amts. of alc. in the medium reduce the R. Q. of both tissues from about 1.00 (lower for roots) without alc. to almost 0.67 (theoretical for alc.) with only a slight increase in O consumption, and part of the alc. disappears. Added glucose increases O consumption slightly. Under complete aerobiosis glucose does not affect the R. Q. if it is approx. 1.00 but increases it under O deficit or if it is already below 1.00. The effect of each substance occurs in the presence as well as in the absence of the other. In nodules, either without added source of C or with glucose, increasing the O concn. leads to increased carbohydrate breakdown, as shown by the CO_2 evolved and O consumed; while in roots, without added C source or with alc. and nodules with alc., increasing the O concn. leads to decreased carbohydrate breakdown. The results indicate that alc. may be an intermediate in normal plant respiration. Felix Saunders

Chlorophyll as the prosthetic group in the green leaf. Emil L. Smith. *Science* **91**, 199–200(1940).—In purified chloroplast material there is a const. relation of about 16 parts of chlorophyll to 100 parts of protein. This relation indicates a little over 3 mols. of chlorophyll per Svedberg unit of 17,000 mol. wt. The fraction over 3 may represent an extra chlorophyll b mol. The action of the detergent Na dodecyl sulfate (SDS) was studied. In addn. to clarifying completely the green pigment, SDS also quantitatively converts the chlorophyll into pheophytin. This conversion proceeds at a rate which is directly proportional to the pH and takes place even at pH 8–9. At const. pH, the rate is proportional to the SDS concn. Pheophytin formation does not occur in 4% digitonin or 10% bile salts at pH 4.5. At this pH in 0.05% SDS the reaction is complete in a few min. Mg probably does not play a part in binding chlorophyll to the protein but it may be concerned in the binding of larger units. Felix Saunders

A study of the green pigments in the lotus embryo. Robert Stewart and H. Clyde Eyster. *Proc. S. Dakota Acad. Sci.* **19**, 89–91(1939).—In the lotus embryo green pigments form in the absence of light. Analyses showed that only chlorophyll b and no chlorophyll a is present. Carotene and xanthophyll were present in normal amts. Walter H. Seegers

Histology of some physiological disorders of the apple fruit. Mary MacArthur. *Can. J. Research* **18, C**, 26–34 (1940).—The histological similarities and differences between the boron-amenable disorders, internal cork, corky core and drought spot, and the non-boron-amenable disorder bitter pit are presented. Blotchy pit is discussed as a borderline type, since one end of a graded series is similar to internal cork and the other is indistinguishable from bitter pit. On the basis of histology water core is not placed in either of the two groups. Starch retention, in localized or diffuse necrotic areas, is common to both groups of disorders. External papillations occur on the walls of cells in close proximity to the lesions. Abnormal meristematic activities coexist with boron deficiency. These are (1) a cork cambium partially or completely walling off a lesion, (2) massed linear cells, heavily papillated, and (3) reactivated individual cells or groups of cells. All three types of abnormal cells may be present in internal cork and drought spot, but no cork cambium occurs in corky core. J. W. Shipley

The composition of the macrospores and of the microspores of Selaginella. Antonio Sosa and Cécile Sosa-Bourdouil. *Compt. rend.* **210**, 59–61(1940); cf. *C. A.* **32**, 5868[8].—The microspores of *Selaginella spinulosa* A. Br.

are higher in percentages of ash and protein N and lower in crude fat than the macrospores. The fat of the microspores has a higher proportion of unsaponifiable matter and has a higher I no. There is no difference in total N. J. T. Sullivan

The modification of karyokinesis and cytodieresis in the plant by cyclic hydrocarbons and their derivatives. Pierre Gavaudan, Noelie Gavaudan and Joseph F. Durand. *Compt. rend.* **210**, 114–16(1940); cf. *C. A.* **33**, 2985[5,4], 3893[9], 5505[3], 6387[3], 8686[6].—The systematic study of hydrocarbons and their derivs. and a comparison of their phys. properties with their activity and toxicity are recommended as an approach to the problem of their selective effect on karyokinesis and cytodieresis. J. T. S.

A factor influencing nitrogen excretion from leguminous root nodules. Artturi I. Virtanen and Maila Torniainen. *Nature* **145**, 25(1940).—The authors suggest that the discrepancies in their results and those of others on the excretion of N compds. from leguminous roots may be ascribed to the quality of the containers, and especially to their porosity. The pots giving best results should be large and very porous. E. D. Walter

Utilization of nitrogen by Ophiobolus graminis. S. D. Garrett. *Nature* **145**, 108–9(1940).—Expts. show that a pure culture of *O. graminis* growing on sterilized wheat straw can utilize nitrate N. This supports the conclusions of Padwick (*C. A.* **30**, 6409[4]). E. D. Walter

Salt absorption of plants. H. Lundegårdh. *Nature* **145**, 114–15(1940).—Discussion, with a reply to Hoagland and Steward (*C. A.* **33**, 7846[6]). E. D. Walter

Salt absorption of plants. D. R. Hoagland and F. C. Steward. *Nature* **145**, 116–17(1940); cf. preceding abstr.—A discussion suggesting the complexity of the problem of salt absorption by living cells and also that the theory of Lundegårdh has not yet been established and generally accepted by plant physiologists. E. D. W.

Fats of marine algae (Takahasi, *et al.*) **27** Seasonal variation in Co content of North Island pastures (McNaught, Paul) **15**. Surface migration of ions and contact exchange [nutrition of plants] (Jenny, Overstreet) **2**

Biological value of the proteins of some species of Bengal fish by the nitrogen balance and growth methods. K. P. Basu and K. Gupta. *J. Indian Chem. Soc.* **16**, 543–8(1939).—The biol. value of the proteins of some common species of Bengal fish, viz., katla, mrigel, air, koi, singhi, sarputi, poa and koral, has been detd. by the N balance and by the growth methods previously used by Basu and De for the common varieties ruhee and hilsa (*C. A.* **33**, 4645[6]). The digestibility (83 97%) and biol value (70 88%) are both very high, and in young rats growth per g. of protein ingested varies from 1.48 to 1.83 per day. The different fishes contain a large percentage of proteins of very good quality and their consumption as a daily article of food by the Bengali is an excellent custom. C. R. Addinall

The prothrombin content [of the blood] in relation to early and late feedings of the newborn. A preliminary report. Leif Salomonsen and K. K. Nygaard. *Acta Paediat.* **27**, 209–18(1939)(in English); cf. *C. A.* **34**, 483[6].—Hypoprothrombinemia (I) occurred in 11 out of 12 infants who received regular breast feedings beginning 12–20 hrs. post partum, but was not found in infants who were given extra feedings beginning 2 hrs. post partum. Excessive I does not normally follow a moderate period (up to 34 hrs.) of "abs. diet" (as sterile water), but can appear after a longer period. The observed prothrombin variations can hardly be caused by variations in the intake of vitamin K, since milk contains little vitamin K. Early extra feedings of the newborn may hasten the bacterial metabolism in the intestines, thus creating a supply of vitamin K sufficient for the prevention of a relative transitory I. Ruth Berggren

Leprosy and nutrition in New Zealand. Emmo Gehr. *Arch. Schiffs- u. Tropen-Hyg.* **44**, 73–8(1940).—Central Europe and New Zealand furnish examples of the simultaneous disappearance of leprosy with the removal of a sapotoxin-contg. component of the diet. This confirms the theory of Oberdorffer (*C. A.* **33**, 5033[4]). Ruth Berggren

Effect of renal retention of vitamin C on saturation tests. A formula for compensation of this factor of error. John B. Ludden and Irving Wright. *Arch. Internal Med.* **65**, 151–62(1940).—Details of a vitamin C-satn. test are given. The patient after 12 hrs. on a low-vitamin C diet is given intravenously 1 g. ascorbic acid dissolved in 10 cc. saline soln. Blood ascorbic acid is detd., and also the urinary excretion. During the 1st 5 hrs. 54–99% of the 1st 24-hr. excretion appeared in the urine, the amt. depending on the state of satn. of the patient and the vitamin C renal function. The data showed a definite correlation between (1) the percentage of the 5-hr. output excreted in the 1st 1.5 hrs. and (2) the percentage of the 24-hr. output excreted during the 1st 5 hrs. Plotting these two sets of values gave a straight-line relation. The following working formula was developed: $C = ab/(1.26\,a - 0.27\,b)$, where C represents the amt. of vitamin C in mg. excreted in 24 hrs., a the amt. excreted in 1.5 hrs. and b the amt. excreted in 5 hrs. J. B. Brown

Turkey poults need four times as much vitamin A as chicks. H. S. Wilgus, Jr. *Colo. Agr. Expt. Sta., Farm Bull. Quart.* 2, No. 1, 2–3(1940).—Max. growth and min. mortality with poults were obtained on 600 units vitamin A per 100 g. of ration. With 300 units per 100 g., 22% of the poults died. C. R. Fellers

Growth of rats on high-fat and low-fat diets, deficient in the essential unsaturated fat acids. R. G. Sinclair. *J. Nutrition* 19, 131–40(1940).—On a diet of casein, salt mixt., dried yeast and the fat elaidin, supplemented with vitamins A and D, rats cease growing when about 100 g. in wt., decline in health and finally die. Growth and health are immediately restored by feeding small amts. of corn oil. This indicates a deficiency in the 1st diet of essential unsatd. fat acids. Replacement of elaidin by sucrose also gives rapid wt. increase. A similar, though smaller, gain occurs when the elaidin diet is replaced by one rich in carbohydrate and very poor in fat. Conclusion: The better growth on the high-carbohydrate rather than on the high-fat diet is partially due to the synthesis of the fat acids necessary for growth. An increase in the requirements of essential fat acids by rats on a high-fat diet may also contribute to poor growth. C. R. Fellers

Influence of urea ingestion on the nitrogen balance and energy metabolism in rats. Max Kriss and Lawson F. Marcy. *J. Nutrition* 19, 151–60(1940).—When urea was fed to rats at the rate of 2 g. daily, 95.5% was recovered in the urine and 0.7% in the feces. Urea had no effect on either heat production or R. Q. Conclusion: Rats do not utilize urea to any significant degree and excretion of urea does not exert a sp. dynamic effect C. R. Fellers

Iron and copper versus liver in the treatment of hemorrhagic anemia in dogs on milk diets. D. V. Frost, V. R. Potter, C. A. Elvehjem and E. B. Hart. *J. Nutrition* 19, 207–11(1940); cf. *C. A.* 33, 6965. Cu in addn. to Fe is necessary for hemoglobin production in dogs. Whole milk, with addnl. Fe and Cu, can successfully meet the great increase in demand for blood-forming elements occasioned by severe blood losses. Milk-diet regeneration of hemoglobin was no more rapid with liver therapy than with Fe-Cu treatment. C. R. Fellers

Influence of different levels of fat in the ration upon milk and fat secretion. Gale Gibson and C. F. Huffman. *Mich. Agr. Expt. Sta., Quart. Bull.* 21, 258–64(1939).—The addn. of soybean oil meal in place of an isodynamic amt. of beet pulp to the basal ration resulted in temporary increase in butterfat percentage. The addn. of soybean oil to the basal ration low in fat gave an increase in milk production. An increase in production was also noted when corn replaced beet pulp, but the fat content remained unchanged. A low-fat ration resulted in an increase in the percentage of fat in milk. Conclusion: The basal ration is an important factor in detg. the effect of the addn. of fat on milk and fat secretion. C. R. Fellers

Salt requirement of growing pigs. R. D. Sinclair. *Sci. Agr.* 20, 109–19(1939).—In general, the addn. of NaCl to pig rations did not result in significant increases in the rate of gain. However, the addn. of 0.5% NaCl to grain rations should meet all requirements, though feeding up to 3% of the ration did not give rise to excessive retention of moisture in muscle samples and did not exert any significant effect on dressing percentage. Feeding NaCl up to 3% of the ration led to a marked increase in water consumption and excessive urination. C. R. F.

Digestibility studies with ruminants. V. Associative digestibility among roughages and succulent feeds. C. J. Watson, W. M. Davidson, J. C. Woodward, C. H. Robinson and G. W. Muir. *Sci. Agr.* 20, 175–92(1939); cf. *C. A.* 33, 8711⁴.—Associative digestibility is defined as a change in digestibility of a feed due to its incorporation in a ration with 1 or more other feeds. With Shorthorn steers, there was no associative effect as far as total digestibility and total digestible nutrients were concerned with hay, oat straw, corn silage and mangels. The digestibility of oat hulls, calcd. from a mixed ration with either hay, corn silage or mangels, was lower than the digestibility observed when oat hulls constituted the sole ration. The digestibility of the N did not generally follow the trend of total digestibility. In the case of the addns. of hay to silage and mangels, the digestibility of the N decreased, whereas in the case of the addn. of hulls to hay or silage, the digestibility of the N in the mixed ration increased.

VI. Associative digestibility of grains: barley, oats and oil cake. C. J. Watson, J. A. Campbell, W. M. Davidson, C. H. Robinson and G. W. Muir. *Ibid.* 238–53.—There was no associative effect between barley and oats. In the case of the barley-oats-oil cake combination, there was no associative effect as far as Et_2O ext. and protein were concerned. C. R. Fellers

Iron metabolism. I. Role of calcium in iron assimilation. S. W. Kletzien, K. W. Buchwald and L. Hudson. *J. Nutrition* 19, 187–97(1940).—Young rats were fed a milk diet productive of a severe anemia, and the effect of variation in the supply of Ca on the amt. of Fe in the various body organs and body itself was then studied. The addn. of 1 and 3% $CaCO_3$ to the basal diet resulted in lower tissue-Fe values. This was also true when Ca in the form of lactate equiv. to 2.5% and of chloride and tertiary phosphate equiv. to 3% of $CaCO_3$ were fed. This was not true for $CaSO_4$. The addn. of 1 and 3% $CaCO_3$ to a basal diet contg. 90% ground whole wheat resulted in lower tissue-Fe values. The possible bearing of these findings on the metabolism of minor elements is discussed. C. R. Fellers

Protein content of the organs and tissues at different levels of protein consumption. T. Addis, D. D. Lee, W. Lew and L. J. Poo. *J. Nutrition* 19, 199–205(1940); cf. *C. A.* 31, 743⁸.—In isocaloric diets contg. 6, 11, 16, 27 and 43% protein, greatest total gain in rats occurred on the diet contg. 27% protein. However, each organ and tissue had its own mode of reaction to an increasing supply of food protein. Some organs made their max. gain of protein at the 16% level, some at 27% and still others at 43%. Each level of protein intake was assocd. with its own characteristic pattern of distribution (organ protein per 100 g. of total protein). C. R. F.

Ascorbic acid metabolism of college students. E. Neige Todhunter, *et al. Wash. Agr. Expt. Sta., Mimeographed Progress Rept., Coop. Regional Project Northwest States* **1937–38**, 23 pp.—This is a report of a coöperative project of the Expt. Stas. of Mont., Ore., Utah and Wash. Tables of data and graphs show the excretion of ascorbic acid of college women while on their customary diets and following a single massive dose of 600 mg. of ascorbic acid. A satisfactory urine preservative consisted of 75 cc. 5 *N* H_2SO_4, 1 cc. 8-hydroxyquinoline (1.45 g. hydroxyquinoline in 100 cc. EtOH) and 5 cc. of toluene. If necessary, before titration the pH of the urine was adjusted so that it was not above pH 3.0. The 2,6-dichlorophenolindophenol titration method was used to det. the ascorbic acid present in the urine. The loss in ascorbic acid content of urine samples treated with the preservative and allowed to stand for 24 hrs. at room temp. was about 5%. The majority of subjects excreted 15 mg. or more of ascorbic acid daily. Only 7% showed less than 15 mg. In general upper-class women and graduate students showed higher excretion levels than undergraduates. Outgo of ascorbic acid is related directly to intake. Marked variation in percentage excreted occurred when a satn. dose of 600 mg. of ascorbic acid was taken in 1 dose. C. R. Fellers

Dietary protein and the toxicity of sodium selenite in the white rat. Howard B. Lewis, Julius Schultz and Ross A. Gortner, Jr. *J. Pharmacol.* 68, 292–9(1940).—Diets contg. 30% of casein afforded young rats much more protection against Se intoxication (Na_2SeO_3 at levels of 25–50 p. p. m. Se mixed with the food) than did diets of equal caloric value contg. 6% of casein. Methionine (0.45–0.89%) added as a supplement to the 6% casein diet afforded marked protection, whereas cystine afforded none. Supplementary methionine added to a diet contg. 15%

of arachin, a protein very low in methionine, as the only protein afforded protection against the toxic action of Se. L. E. Gilson

Vitamin A contents of liver oils of Argentine fish. Ascensión O. Castellanos. *Rev. inst. bacteriol. dept. nacl. hig.* (Buenos Aires) **9**, 227-37(1939).—Numerous species from the coastal waters were exaind. All the oils compared favorably with cod-liver oil. L. E. Gilson

Nicotinic acid deficiency encephalopathy. Norman Jolliffe, Karl M. Bowman, Louis A. Rosenblum and Harry D. Fein. *J. Am. Med. Assoc.* **114**, 307-12(1940). —Treatment of 22 patients having encephalopathic syndrome with 0.5-1.0 g. nicotinic acid daily resulted in the recovery of 15 individuals. Treatment with thiamine chloride was less effective. F. P. Griffiths

Cutaneous manifestations of vitamin A deficiency in children. Edward Lehman and Howard G. Rapaport. *J. Am. Med. Assoc.* **114**, 386-93(1940).—Skin lesions consisting of horny papules formed by keratotic plugs projecting from hair follicles are reported as signs of vitamin A deficiency in children. Improvement follows daily dosage with 100,000-300,000 units of vitamin A. Numerous references are cited. F. P. Griffiths

Vitamin A in the blood of normal adults. Grace Steininger, Lydia J. Roberts and Sadie Brenner. *J. Am. Med. Assoc.* **113**, 2381-7(1939).—The amt. of vitamin A and carotene was detd. in the blood of 1 control and 4 exptl. subjects during a four-month depletion study. The amt. of vitamin A in the blood was dependent on the amt. in the diet. There was no correlation between the vitamin A in the blood and the biophotometer readings. F. P. Griffiths

Nicotinic acid in the cure of pellagra. F. Mancini, M. Della Corte and V. Leone. *Quaderni nutriz.* **6**, 374-93 (1939).—A study was made of clinical cases. The intravenous or intramuscular injections were most favorable therapeutically. Helen Lee Gruehl

Biological activity of oxidized ascorbic acid (dehydroascorbic acid). Renzo Vendramini and Livio Olivetti. *Quaderni nutriz.* **6**, 394-406(1939).—Aq. solns. of ascorbic acid aerated for 24 hrs. diminish in titer chemically but retain their biol. antiscorbutic activity. H. L. G.

Method of introduction of ascorbic acid. Renzo Vendramini and Livio Olivetti. *Quaderni nutriz.* **6**, 407-24 (1939).—In guinea pigs intramuscular introduction of ascorbic acid proved best in combating exptl. scurvy. Helen Lee Gruehl

Plants and vitamins. I. Vitamin C and plant enzymes. M. A. Gudlet. *Botan. Zhur.* **23**, No. 3, 237-51(1938); *Khim. Referat. Zhur.* **2**, No. 5, 52(1939).—A summary of chem. properties and transformations of ascorbic acid. W. R. Henn

Vitamin E. F. Gstirner. *Chem.-Ztg.* **64**, 45-7(1940). —A review of occurrence, constitution, synthesis and therapeutic use. E. H.

The significance of the "trace elements" in nutrition. E. J. Underwood. *Nutrition Abstracts & Revs.* **9**, 515-34(1940).—A review. E. H.

Concentration of pyruvic acid in normal and avitaminotic blood. Hans v. Euler and Bertil Hogberg. *Naturwissenschaften* **27**, 769-70(1939).—Lack of vitamin B_1 causes an increase in pyruvic acid concn. of the blood and of the brain due to the normal decompn. of the acid by pyruvic acid apodehydrase with phosphorylated vitamin B_1 as coenzyme. Appreciable increases in pyruvic acid content for rats on a vitamin B_1-free diet follow: normal blood 12-13 γ per cc., after 12 days without vitamin B_1 25-7 γ, after 20 days 34 γ, in some cases as high as 43-5 γ. A similar increase in pyruvic acid content of blood also occurs in the presence of normally ample amts. of vitamin B_1 (30% fresh bakers' yeast in the diet) if vitamin A is absent. After 12 days of vitamin A-free diet there is 42 γ per cc. blood, after 20 days 60 γ per cc. Avitaminosis D does not affect the pyruvic acid content. Addn. of β-carotene to the diet again reduces the pyruvic acid concn. of the blood. Addn. of a daily addnl. dose of 1 g. fresh bakers' yeast to a normal rat diet low in vitamin A also reduces the pyruvic acid content. Hence in the absence of vitamin A more than the usual amt. of vitamin B_1 is required. It is suggested that besides the oxidation-reduction effects of vitamin A its effect on the condition of the mucous membranes may be significant as it affects the vitamin B_1 resorption rate. B. J. C. v. d. H.

Tissue changes in ascorbic acid-deficient guinea pigs. D. L. MacLean, M. Sheppard and E. W. McHenry. *Brit. J. Exptl. Path.* **20**, 451-7(1939).—Tissue changes resulting from an acute deficiency of ascorbic acid in guinea pigs, studied by the paired feeding technique so that the variable factor of inanition may be controlled, show that the principal abnormalities are in the bones and teeth. In both these cases the vitamin deficiency causes a failure in those sp. cells which are concerned with the formation of calcific tissue. There is no evidence to support the view that the changes are the result of the failure of specialized cells to secrete some substance which normally produces jellying of collagenous material. Characteristic changes in other tissues have not been obtained. The inanition coincident with the development of ascorbic acid deficiency is not responsible for any of the observed histological changes. Harriet F. Holmes

The glutathione content of the blood and certain organs in experimental scurvy. L. D. Kashevnik, S. A. Eidman and I. B. Fridlyand. *Voprosy Pitaniya* **8**, No. 4, 44-9 (1939).—Experimental scurvy in guinea pigs results in a decrease from 40 to 33 mg. % in reduced glutathione (I) and an increase from 5 to 11 mg. % in oxidized I in the blood. There is an increase in reduced I in the liver and kidneys, with occasional slight increases in oxidized I. There is a decrease in both reduced and oxidized I in the adrenals. S. A. Karjala

Ocular manifestations of ariboflavinosis. H. D. Kruse, V. P. Sydenstricker, W. H. Sebrell and H. M. Clecklev. *U. S. Pub. Health Repts.* **55**, 157-69(1940).—Seven references. J. A. Kennedy

Nature of vitamin B and its components with special reference to nerve deafness. Clarence A. Veasey, Jr. *Arch. Otolaryngol.* **31**, 74-93(1940).—The literature on vitamin B is reviewed up to Jan., 1938, including a discussion of the chem. nature and physiol. effects of the various fractions, the clinical symptoms of deficiency, the various units employed, the natural sources and the human requirements. V. found it impossible to formulate a definite clinical syndrome for mild vitamin B deficiency and found no lab. procedure for the detn. of vitamin B applicable to ordinary clinical practice. Seven cases of deafness were treated by vitamin B. The results vary, but suggest that there is a possibility that vitamin B therapy may help some deaf persons. D. A. Meyer

Behavior of glycogen and lipides under various nutritional states. Korenori Ono. *J. Biochem.* (Japan) **30**, 351-75(1939).—Male albino rats were fed a basal diet of unpolished rice and vegetables. A synthetic vitamin B-free diet was also fed, and various animal groups were either on high-protein, high-fat, high-carbohydrate or high-cholesterol addns. Liver, muscles and adrenals were analyzed for glycogen, neutral fat, phosphatide and cholesterol. The liver made up 3.5-4.0% of the total body wt. The liver glycogen of the non-fasting rat was, on the av., 3.53% (2.83-4.17%), phosphatide 3.58% (3.53-3.65%), free cholesterol 215 mg. % and bound cholesterol 38 mg. % (av.). For muscles the av. values were: glycogen 0.739, phosphatide 0.92, total cholesterol 0.066, of which 0.063% was free. Vitamin B deficiency causes a large decrease in liver glycogen and lipides, but the muscle glycogen remains unaffected. The muscle cholesterol increases but the neutral fat content is considerably diminished. The high-protein diet causes a decrease in liver glycogen and neutral fat, but affects the muscles to a negligible extent. On the high-fat diet there is a striking increase in the neutral fat and cholesterol (free and bound) content of the liver. The increase in the muscles is not as large. A high-carbohydrate diet results in a slight increase in glycogen and total lipides of both liver and muscles. The changes in the adrenals are not appreciable. The addn. of cholesterol to the diet does not seem to influence the glycogen but causes an increase

in total lipide content which, in the liver, is very large, including both the cholesterol (chiefly bound) and neutral fat but not the phosphatide. In the muscles the changes are not very significant. In the adrenals cholesterol feeding occasions only a marked rise in the bound cholesterol. S. Morgulis

Mode of action of calciferol in the nephrectomized rat. W. R. Tweedy, R. D. Templeton, Mary C. Patras and F. A. McJunkin. *Endocrinology* **26**, 481–4(1940); cf. *C. A.* **33**, 5037[6].—The subcutaneous administration of massive doses of calciferol prevents the fall in serum Ca which usually occurs after thyroparathyroidectomy in the nephrectomized rat. Calciferol produces no effect on the serum Ca of the nephrectomized rat that is thyroparathyroidectomized 1 week prior to nephrectomy. The action of calciferol is on the bowel where it decreases the fecal excretion of Ca. Felix Saunders 2

Relationship of vitamin E (tocopherols) to the endocrine system. J. C. Drummond, R. L. Noble and Margaret D. Wright. *J. Endocrinol.* **1**, 275–86(1939).—Vitamin E when administered to immature or hypophysectomized adult rats does not exert any effect on the ovaries, uterus or vagina. The pituitary glands of E-deficient male rats contain an increased amt. of gonadotropic hormone. Glands from E-deficient female rats show a decreased amt. of luteinizing hormone when tested on hypophysectomized rats. The ovaries of E-deficient female rats respond normally to exts. of pregnant mare serum. In E-deficient male rats such exts. produce only stimulation of the interstitial cells of the testes and do not affect the degenerated tubules. Hypophysectomy of E-deficient male animals is followed by a further decline in wt. of the testes. In such animals pregnant mare serum stimulates only the interstitial elements of the testes. The suggestion that the effects of vitamin E deficiency are produced by hormonal imbalance is not supported by the exptl. evidence. Felix Saunders 3 4

On "**a new color reaction for vitamin B_1 (thiamine, aneurin).**" Guy E. Youngburg. *Science* **90**, 566 (1939); cf. *C. A.* **33**, 8664[9]. —Thiamine does not give a blue color by the Fiske and Subbarow method (*C. A.* **20**, 1092) nor by the $SnCl_2$ reduction. Thiamine does not interfere in P detns. Felix Saunders

Availability of the iron in dried peas and beans. Leah Ascham, Mary Spiers and Dorothy Maddox. *Science* **90**, 596–7(1939); cf. *C. A.* **33**, 1015[4].—Fe in black-eyed peas, green and yellow split peas, navy beans, pinto beans and butter beans is completely available to the nutritionally anemic rat for the regeneration of hemoglobin. Felix Saunders 6

Defect in the metabolism of aromatic amino acids in premature infants: the role of vitamin C. S. Z. Levine, Eleanor Marples and H. H. Gordon. *Science* **90**, 620–1 (1939).—A no. of premature infants were found to excrete in the urine substances giving a pos. Millon reaction. *l,p*-Hydroxyphenyllactic acid was isolated and the presence of *p*-hydroxyphenylpyruvic acid strongly indicated. These substances are absent from the urine of premature infants receiving human milk, while their excretion is increased by feeding phenylalanine or tyrosine. When vitamin C is added to the diet there is a prompt decline almost to 0 of the excretion of these compds. F. S. 7

Theory of protein metabolism: transformation of proteins. Carl L. A. Schmidt, Frank Worthington Allen and Harold Traver. *Science* **91**, 18–19(1940).—Synthesis of proteins can take place in the body by the transformation of existing proteins into others without first being broken down into amino acids. Felix Saunders 8

Vitamin K. E. A. Doisy, S. B. Binkley, S. A. Thayer and R. W. McKee. *Science* **91**, 58–62(1940).—A historical review of the work on vitamin K of the last decade. The distribution, methods of assay, isolation, structure and physiol. properties are discussed. Felix Saunders 9

Effects of a beef-liver fraction on fat synthesis in rats. E. W. McHenry and Gertrude Gavin. *Science* **91**, 171 (1940).—Beef liver contains a substance that markedly stimulates fat synthesis when fed to vitamin B-deficient rats. The total cholesterol of the liver is also increased. The fatty liver thus produced is highly resistant to the lipotropic action of choline but readily responds to lipocaic. A rapid means of assaying the potency of prepns. of *lipocaic* is thus available. Felix Saunders 1

The physicochemical state of calcium in the serum of the ruminant. Santosh Chandra Ray. *Biochem. J.* **33**, 1599–1605(1939).—Sheep fed a P-deficient diet showed an increase in serum Ca and a decrease in inorg. P. This condition was reversed when P was restored to the diet, the fall in the Ca being due chiefly to a decrease in the Ca ion and protein-bound Ca. Addn. of $CaCO_3$ at this point caused a marked reduction in the serum inorg. P. Starvation reduced the total serum Ca, chiefly the Ca ion and protein-bound Ca, and increased the inorg. P. Sheep and goats showed this response to a greater extent than cows. The unreliability of the const. relating serum Ca and serum protein derived by application of the McLean-Hastings mass law equation (*C. A.* **29**, 2217[1]) was pointed out. E. W. Scott

Criticism of Shute's serum test for vitamin E deficiency. W. F. J. Cuthbertson and J. C. Drummond. *Biochem. J.* **33**, 1621–5(1939); cf. Shute, *C. A.* **33**, 6891[2].—Contrary to S.'s results, it was not possible to differentiate between the serum of normal and vitamin E-deficient rats by measuring the rate of proteolysis since there was no difference in rate. Theelin when added to normal serum did not affect the rate of proteolysis. E. W. Scott

Thyroxine and hypervitaminosis A. Carl A. Baumann and Thomas Moore. *Biochem. J.* **33**, 1639–44(1939).—Thyroxine failed to counteract the effects of feeding rats excess vitamin A. Animals receiving both thyroxine and an excess of vitamin A ate less, lost wt. rapidly and died earlier than those receiving either compd. alone. The injection of thyroxine produced a temporary decrease in food intake, followed by a marked increase. No evidence was obtained for a sp. antagonism between thyroxine and vitamin A. E. W. Scott 5

The retention of calcium by the rat in the presence and absence of vitamin C. Kathleen M. Henry and Stanislaw K. Kon. *Biochem. J.* **33**, 1652–4(1939); cf. *C. A.* **33**, 5905[2]. —The addn. of 2 mg. daily of ascorbic acid had no effect on the retention of Ca by rats receiving a diet low in Ca, adequate in P and devoid of vitamin C. The Ca was mainly derived from $CaHPO_4.2H_2O$. E. W. S.

Phytic acid and the rickets-producing action of cereals. Douglas C. Harrison and Edward Mellanby. *Biochem. J.* **33**, 1660–79(1939). —In expts. designed to det. the constituent of oatmeal responsible for its rickets-producing effect, it was found that phytic acid (I) and neutral Na phytate (II) prepd. from com. phytin were very active in producing rickets when they were added to a non-rachitogenic or slightly rachitogenic diet; the degree of activity was roughly comparable to that shown by oatmeal when fed in an amt. equiv. as regards phytic acid P; the phytic acid P fraction extd. from the oatmeal itself had the same activity and purified II from this ext. was equally potent; the rachitogenic activity of II, as of cereals, was counteracted by adding extra Ca to the diet and com. phytin (Ca Mg phytate) was slightly antirachitic. The results suggest that the rachitogenic action of cereals is normally due to the action of the cereal I in inhibiting the absorption of Ca and not to the unavailability of the cereal P. The amt. of I in oatmeal was approx. twice that required to ppt. the Ca of the cereal at neutrality and it is likely that I inhibits the absorption of Ca from other sources in addn. to the cereal Ca. E. W. Scott

Sex variation in the utilization of iron by anemic rats. Louise Otis and Margaret C. Smith. *Science* **91**, 146–7 (1940); cf. *C. A.* **31**, 7494[8].—At the end of an Fe-depletion period the total Fe contents of male and female rats were 0.7065 and 0.8073 mg. Fe, resp., or 0.015 mg. per g. of rat for both. After feeding $FeCl_3$ supplements to anemic rats the mg. Fe per g. of rat was higher for females than for males comparably fed. At the lowest levels of Fe fed (50 γ daily for 6 weeks) the females retained more total Fe (3.3083 mg.) than the males (2.3666 mg.) in spite of their smaller size. D. S. Searle

The concentration of vitamin D in the blood of dairy

cattle as compared with the potency of the milk produced. G. C. Wallis. *Proc. S. Dakota Acad. Sci.* **19**, 55-60 (1939).—Holstein and Jersey cattle were compared. Both breeds were given 7500 international units of vitamin D daily during the lactation period. The amts. of vitamin D in blood samples were the same for the 2 breeds and so were the concns. in butterfat. However, the Jersey breed produces more butterfat and consequently the total amt. of vitamin D produced by that breed is also high. Walter H. Seegers

Comparative studies between Kaschin-Beck disease produced by excess feeding of iron and osteopathia acidosa produced by excess feeding of sucrose. Kuninosuke Hotta. *J. Oriental Med.* **31**, 1191-7(German abstr. 78) (1939).—Young rabbits fed a normal diet plus 1 cc. daily of water contg. 0.4 g. Fe per 100 cc. for 2 weeks grow normally, but gradually blood acidosis is produced and their blood contains excess Fe and extremital bones show osteopathia acidosa. Those fed a normal diet plus excessive sucrose show the same pathol. symptoms. The excessive intake of Fe *per se* cannot be the cause of Kaschin-Beck disease, since the similar feeding plus $CaCl_2$ that produces blood alkalosis lessens pathol. symptoms, in spite of the fact that the blood Fe is high. S. Tashiro

Effects of changes in dietary calcium on neuromuscular transmission. G. L. Brown and A. M. Harvey. *J. Physiol.* **97**, 330-7(1940). A kid, kept on a diet deficient in Ca, showed a defect in neuromuscular transmission, such that a single max. motor nerve volley failed to elicit a max. response from the muscle. With repeated stimulation, at a sufficiently high frequency, each successive response of the muscle became greater until transmission was fully restored at the 5th or 6th response. Chicks on a similar diet reacted in the same way. A diet rich in Ca did not eliminate the normal peculiarity in neuromuscular transmission in the fowl. E. D. Walter

Calcium and synaptic transmission in a sympathetic ganglion. A. M. Harvey and F. C. MacIntosh. *J. Physiol.* **97**, 408-16(1940); cf. preceding abstr. The effects of changes in ionic equil. on synaptic transmission and the activity of ganglion cells were studied in the perfused superior cervical ganglion of the cat. When Ca is absent, there is no release of acetylcholine from the preganglionic nerve endings, either during stimulation of the sympathetic trunk or following the injection of K salts. E. D. Walter

Effects of increased metabolism on ketosis of depancreatized dogs. S. B. Barker. *J. Physiol.* **97**, 394-407 (1940).—The depancreatized dog in the early stages of fasting was used in a study of the production of ketone bodies from fat, in order to eliminate antiketogenic factors. In a series of 3-hr. basal periods with 17 depancreatized dogs, the excretion of acetone bodies was about 10% of the amt. calcd. on the basis of one 4-C residue from each fat acid oxidized. In 80% of the expts., the ketone excretion was less than that which could be derived theoretically from the protein being broken down. In 18 exercise expts. the excretion of acetone bodies decreased in 4, despite the increased oxidation of fat shown by the respiratory exchange. In the rest, the increased excretion of ketone bodies could not be correlated with calcd. yields. In 8 of 11 expts. in which dinitrophenol was used, the excretion of ketone bodies either decreased or was unchanged. The extra acetone obtained in the other 3 was but a small fraction of the calcd. amt. E. D. Walter

Seasonal variation in Co content of North Island pastures (McNaught, Paul) **15**. Cyclization of vitamin A_2 (Embree, Shantz) **10**.

Normal and pathologic muscle fat. Attilio Basile. *Arch. ist. biochim. ital.* **11**, 207-28(1939).—Fat deposition in muscles was studied under a variety of conditions. Lipoid was deposited in the disks of sarcolema, and sometimes caused disappearance of the normal structure, especially after infections produced by *B. diphtheria, B. typhosus, B. coli* and P and As intoxications. E. S. G. Barron

Crystallization of prolan. Pablo Heredia. *Rev. med. cienc. afines* (Buenos Aires) **1**, No. 8, 39-40(1939).—Preliminary observations. E. S. G. Barron

Mammogenic hormones of the anterior pituitary. I. The duct growth factor. A. A. Lewis and C. W. Turner. *Missouri Agr. Expt. Sta., Research Bull.* **310**, 3-72 (1939).—The anterior pituitary secretes (1) a duct-stimulating hormone, and (2) a lobule-alveolar system growth hormone. The former is called *mammogen*. An assay technique involving the use of male mice is described. Pituitaries from 545 cattle were used in this study. A low level of mammogen was found in the anterior pituitaries of fetuses, growing males and steers. The mammogen content of beef and dairy anterior pituitaries was low in early and in late pregnancy rising to a peak about the 150th day. Dairy cow pituitaries contained considerably more mammogen than did beef cattle. During the estrus cycle the mammogen content was highest in the luteal stage. Male rabbits given estrone responded with an increase of mammogen to double the content found in pregnant rabbits. When the estrone dosage was excessive, however, no mammogen was secured. Concn. of mammogen to $^1/_{100}$ of the fresh condition was obtained. Exts. of anterior pituitary developed complete mammary duct systems in male and spayed female mice, spayed female rabbits and hypophysectomized ground squirrels. 83 references. C. R. Fellers

Composition of different skeletal parts of experimental animals. C. E. Weakley, Jr., and R. B. Dustman. *W. Virginia Agr. Expt. Sta., Bull.* **294**, 40 pp.(1939); cf. *C. A.* **33**, 7368[3].—The study includes the rat, chick, pig and calf. In general, the deficient feeding resulted in lighter bones of higher moisture and lower ash content. The pig was an exception, though there were ample physiol. evidences of nutritional deficiencies. The moisture to ash ratio is a sensitive measure of change from normal to abnormal in deficiency studies. There is a natural pairing of the leg bones as to moisture and ash content in relation to skeletal position. The femur and humerus are higher in moisture and lower in ash than the tibia and ulna-radius, while these in turn are higher in moisture and lower in ash than the metatarsus and metacarpus. Bones from the Berkshire breed are lower in fat-extractable substance than those of Poland China or Duroc Jersey breeds. Comparisons of ash on a green basis as compared with a fat-free, moisture-free basis show certain advantages for the former, especially when ash is considered in relation to moisture as moisture to ash ratio. The feeding of rachitic rations to chicks and dairy calves resulted in the production of bone and bone marrow fats of a more highly unsatd. nature than those produced on normal rations. The different rations fed to pigs had little effect upon the percentage of Ca, Mg and P in the bones. A study of bilateral variation in the green wt. of the long bones shows a tendency toward heavier bones on the left side in the chick and pig. Moisture and org. non-fat fraction are highest, as a rule, in bones taken from the left side of the body. 21 references. C. R. Fellers

The copper contents of some bovine organs (fetuses, calves and full-grown animals). Jenő Sárosdi. *Közlemények Összehasonlító Élet. Kórtan Köréből* **27**, 225-32 (1940).—Cu was detd. by the method of Schönheimer

id Oshima (cf. *C. A.* **23**, 2477). The Cu content of the arious organs varies between wide limits; liver contains ost and the male sexual glands the least. The av. Cu con- nt of liver of the grown animal was 4.83 mg., of calves .07 mg. and of the fetus 33.45 mg. per 100 g. dry matter.
S. S. de Finály

The cystine content of the proteins of horse blood erum. Gyula Papp. *Közlemények Összehasonlító Élet. órtan Köréből* **27**, 232-9(1940).—Total protein was etd. both gravimetrically and refractometrically; cystine as detd. according to Rimington (*C. A.* **25**, 309). The v. cystine content of the total protein of horse serum was .86% of the dry matter. The av. total protein content of he serum was 7.86%. The protein ratio decreased during mmunization to diphtheria; this is attributed to the in- rease of globulins. The cystine content varied in proteins epd. by $(NH_4)_2SO_4$ from 1.96 to 2.78; in those sepd. by oiling, from 2.86 to 4.35%. No definite connection could e found between cystine content of the single protein ractions and the immunization against diphtheria.
S. S. de Finály

The cystine contents of the hair and skin of some do- nestic animals. Elek Kovács. *Közlemények Összehasonlító Élet. Körtan Köréből* **27**, 239-44(1940). —For the detn. of ystine Rimington's modification (*C. A.* **25**, 309) of the olm-Looney method is well suited. The mean cystine ontents of the skin and hair, resp., are (calcd. to 100 g. lry matter): horse 0.73, 7.58; ox 0.71, 5.17; pig 0.76, 3.53; dog 0.61, 9.03 g. The cystine contents of skin and air vary according to the part of the body. In the same ype of animal no significant differences were observed n the cystine contents of the hair or skin of the same part.

The quantity of water circulating in the blood plasma. Julien Fliederbaum. *Arch. maladies coeur vaisseaux* **32**, 893-9(1939).—The amt. of water circulating in the blood plasma in dogs is not affected by anemia or ingestion of Na_2CO_3; it is not uniformly affected by injection of digitalis; it is increased by ingestion of water or intrave- nous injection of hypertonic glucose soln., camphor in Na salicylate soln., coramine, corpuline, stiminol, cardiasol or mercurial diuretics (novasurnol and salyrgan); it is de- creased by ingestion of NH_4Cl, subcutaneous injection of morphine with or without ether anesthesia, or intravenous injection of distd. water, chloralose, strophanthin or urea; and it is decreased and then increased by hemorrhage or intravenous injection of euphylline Marion Horn

The bile-secreting function of the liver. S. M. Gorsh- kova. *Arch. sci. biol.* (U. S. S. R.) **54**, No. 2, 22-36 (in English, 36)(1939). —Fistulas were inserted in the gall bladders of dogs in such a way as to keep the bile-secreting system of the liver intact. The latent period of bile secre- tion was found to be considerably shorter than previous expts. had indicated, being 8, 12, 3 and 5 min., resp., for meat, bread, milk and egg yolk. It was also found to be inversely proportional to the hydrostatic condition of the bile-secreting app. of the liver. When the bladder was artificially filled the latent period of secretion was shortened. A division of this period is suggested into a true latent period of excitation and a period of latent activity of the bile-secreting app. Evacuation is also de- pendent upon the hydrostatic condition of the entire sys- tem, and discharge of bile into the intestine can be com- pletely inhibited by the use of an open gall bladder fistula. Food stimulates evacuation and also the secretion of bile- expelling stimulants. S. A. Karjala

Motor function of the gall bladder in man. I. T. Kurt- sin. *Arch. sci. biol.* (U. S. S. R.) **54**, No. 2, 37-52(in English, 52)(1939).—The administration of meat, bread, milk, egg yolk, butter, cranberry juice, HCl and $MgSO_4$ to human beings with gall bladder fistulas produces energetic contraction of the gall bladder. The length of the latent period of passage of bile into the duodenum in man after food consumption is exceedingly short. It is suggested that the mechanism regulating the motor activity of the gall bladder in man involves, besides the vagus and sympathetics, a specific hormone which stimulates the activity of the gall bladder and which is the principal "evacuation motor" of the bile. S. A. Karjala

Bile formation in man. V. M. Shaverin. *Arch. sci. biol.* (U. S. S. R.) **54**, No. 2, 53-64(in English, 64)(1939). —Bile secretion was studied in a patient with a gall bladder fistula. Studies during the course of a day showed a gradual bleaching in the color of the bile to the crest of digestion, at which point the bladder contents were color- less. Administration of H_2O and physiol. saline soln. caused a large increase in bile secretion, with tea, coffee, bouillon and cabbage juice giving a less pronounced effect. Meat, butter, egg yolk and milk caused decolorization of the bile. Bile and HCl did not cause an increase in bile secretion, but the intravenous injection of Na glyco- cholate caused a strong increase. S. A. Karjala

The nature of "mechanical" secretion of the stomach in man. I. T. Kurtsin. *Arch. sci. biol.* (U. S. S. R.) **54**, No. 3, 74-88(in English, 88)(1939).—The action of a mech. stimulus (distended rubber balloon) upon the re- ceptors of the gastric walls produces an increased gastric secretion at first in the minor and later in the major curva- ture of the stomach. The Heidenhain pouch does not respond when isolated. Secretion is stopped by administra- tion of atropine. Mech. stimulation is assocd. with an inhibition of the conditioned-reflex secretion of saliva and an increase in nonconditioned-reflex secretion.
S. A. Karjala

The effect of lung ventilation on gaseous exchange in the quiescent state. V. B. Liberman, R. P. Ol'nyanskaya,

A. D. Slonim and V. N. Gus'kova. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 32–43(in English, 43)(1939).—The amt. of O uptake per l. of excessive ventilation during voluntary hyperventilation varies from 3.3 to 11.3 cc. depending upon the amt. of hyperventilation and rhythm. The max. is obtained at 16 l. and 5 inhalations/min. The ratio of exhaled CO_2 to O consumption showed wide variations, but no regularities were noted. In involuntary hyperventilation (inclusion of a tube in front of the respiratory valve) this ratio remained const. at various hyperventilation values while the O consumption per l. of excessive ventilation decreased slightly. S. A. K. 1

The morphology of distribution and transformation of glycogen. V. Gradient of glycogen accumulation as an index of the histochemical architectonics of the sensory ganglia. A. L. Shabadash. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 146–50(1939)(in English); cf. *C. A.* **34**, 4949.—Cells are divided into 3 classes with regard to glycogen (I) content: A cells (those that have large amts. of I and stain a dark crimson-violet), B cells (those that have medium amts. of I and stain a transparent pink-lilac) and C cells (contg. little or no I). A count of the cells of the ganglion of a kitten showed that of 2886 cells, 654 were A, 877 B and 1335 C cells; so 53.49% of the cells contained I. In the same ganglion the cell sizes were divided into type I (large cells of 45–65 μ and larger), type II (medium cells of 25–40 μ) and type III (small cells of 13–20 μ). The 3 types represented 38.35, 50.31 and 11.34%, resp., of the total. The no. of cells in each type which contained I were 89.35, 35.03 and 17.53% for types I, II and III, resp. Thus the capacity to synthesize and accumulate I is limited to a definite category of the unipolar cells, or the ratio of assimilation to glycogenolysis in the different types of cells varies considerably. S. A. Karjala 2 3 4

The influence of the adrenal hormones on the glutathione content of muscle. V. S. Il'in. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 154–6(1939)(in German).—The contents of total and reduced glutathione (I) in the blood, liver, kidney and muscles of normal cats are 31.1 and 35.5, 242 and 265, 122 and 139, and 31.1 and 33.1 mg.%, resp. In adrenalectomized cats the values are 34.5 and 40.5, 258 and 281, 139 and 168 and 40.5 and 43.0 mg. %, resp., and in cats in which one gland is removed with the adrenal medulla of the other the values are 32.1 and 35.4, 262 and 302, 133 and 178 and 20.8 and 22.2 mg. %, resp. The injection of adrenaline (II) into normal cats does not increase the I content of the muscles, but in the case of cats in which the adrenal medulla is removed the reduced and total I values of 22.7 and 23.6 mg. %, resp., increase to 28.3 and 30.3 mg. %, resp., after injection of II. Conclusion: The I content of muscles is regulated by the adrenal hormones, the cortex hormone decreasing I and the medullary hormone increasing I in the muscles. S. A. Karjala 5 6 7

The effect of age on the passage of bile into the intestine. A. Vorob'ev. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 251–4(1939)(in French).—Bile secretion in young dogs reaches a max. 1 hr. after intake of foods and then decreases slowly. The duration of secretion is much longer in young dogs than in old ones, while the latent period is considerably shorter. S. A. Karjala 8

The dynamics of increase in the gonadotropic activity of the anterior pituitary in pig embryos L. N. Daineko. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 301–4(1939)(in English); cf. *C. A.* **34**, 4956. The amts. of gonadotropic hormone in mouse units in 1 g. of the anterior pituitary gland of pig embryos aged 2.5–3, 3, 3.5 and 4 months and in adult pigs were 29, 50–91, 80–140, 200 and 200 units, resp. S. A. Karjala 9

Change in current fluctuation of the pancreas. Bun-iti Hasama. *Z. Biol.* **99**, 541–50(1939).—Rabbits show 2 kinds of current fluctuation corresponding to the 2 functions of the pancreas: (1) The action current of the excretory cells which accompanies increased secretion of pancreatic juice and fails when secretion is stopped by ligature of the duct; (2) that which accompanies increased blood sugar is independent of secretion of pancreatic juice and is an indication of the action current of the island of Reil. The former is produced by stimulation of the vagus, stimulation of the splanchnic or injection of secretin; the latter results from increased blood sugar. Both types of current fluctuation appear simultaneously when the right vagus is stimulated or adrenaline injected. Frances Krasnow

The comparative behavior of mammalian eggs in vivo and in vitro. V. Effects of mitosis-inhibiting treatments on normally fertilized pre-cleavage rabbit eggs. Gregory Pincus and C. H. Waddington. *J. Heredity* **30**, 515–18(1939); cf. *C. A.* **32**, 3002⁹.—Dil. solns. of alc., ether and colchicine, or brief exposures to subnormal temp. inhibit the normal cleavage rate of fertilized rabbit ova *in vitro*. *Colchicine* not only prevents spindle formation and cytoplasmic cleavage but also inhibits the normal movements of the pronuclei. T. Laanes

The dephosphorylation of 2,3-diphosphoglyceric acid in hemolyzed red blood corpuscles of the horse. Åke Lennerstrand and Margit Lennerstrand. *Arkiv Kemi, Mineral. Geol.* **13B**, No. 15, 5 pp.(1939)(in English).—A small part of the diphosphoglyceric acid (I) of the hemolyzate was broken down in 22 hrs., but it was practically unchanged during that time when phosphate buffer, pH 7.4, was present. Mg and adenylic acid accelerate the breakdown. In the presence of fluoride the breakdown is inhibited and I increases, probably as the result of phosphorylation and transformation of carbohydrates since iodoacetate prevents this increase. Iodoacetate partially inhibits the dephosphorylation. The following scheme is suggested: I → monophosphoglyceric acid (II); II → phosphopyruvic acid (III); III + adenylic acid → pyruvic acid + adenosinediphosphoric acid. The neg. results of Rapoport and Guest (*C. A.* **33**, 7868¹) with hemolyzed corpuscles can be explained by the destruction of adenylic acid by the adenylic acid phosphatase of the blood. H. L. Mason

Recent work on the physiology of the liver. H. Roger. *Presse méd.* **47**, 1104–6(1939).—A review dealing with the metabolism of glycogen and sugar in relation to the endocrine and nervous system and with the mechanism of urea formation. A. E. Meyer

The liver of the rabbit. León Binet, Claude Rouvillois and Daniel Bargeton. *Presse méd.* **47**, 1157–9(1939).—Ligation of the branches of the portal vein supplying some of the lobes is usually tolerated. The lobes deprived of portal blood undergo atrophy whereas the others show compensatory hypertrophy. The blood sugar remains unaffected, but the degenerating lobes show an immediate loss in glycogen and glutathione. A. E. Meyer

Chemical transmission of impulses and excitability. Paul Chauchard. *Presse méd.* **47**, 1494–5(1939).—A discussion. A. E. Meyer

Prothrombin studies, especially in the newborn. W. E. Bray and Orville R. Kelley. *Am. J. Clin. Path.* **10**, 154–67(1940).—The prothrombin (*P*) time in the newborn is not significantly related to the platelet count. The *P* of cord blood is usually low and it is somewhat lower than that of the infant's blood taken within 24 hrs. after birth. *P* is very variable in the newborn, tending to be within the normal adult range for the 1st day and rising to a peak definitely higher between the 2nd and 5th days, usually becoming normal again after the 5th day. *P* is very high in hemorrhagic disease of the newborn, and it may be high without any tendency to bleeding. There was no tendency to bleeding in cases with a low *P*. John T. Myers

Blood cytology of the normal dog. M. L. Morris, James B. Allison and David F. Green. *J. Lab. Clin. Med.* **25**, 353–60(1940).—From a group of 1000 dogs under routine hospital conditions, 66 dogs of different ages, breeds and sexes were selected for the study. The no. of red blood cells (RBC) and the concn. of hemoglobin (Hb) increase from 2 months of age to puberty (8 months) in a majority of the breeds. The av. values of the RBC count and the Hb concn. of 35 young dogs within this age range are 5.3 millions per cu. mm. and 12.6 g. per 100 cc., resp.; for 31 older dogs the av. values of these constituents are 6 million and 15.1 g. The av. corpuscular Hb (Hb concn./no. of RBC) is equal to approx. 24×10^{-12} g. and there is no

marked effect of age, breed or sex upon this value. The Hb concn. in the adult dogs was not influenced by the breed or sex. The av. white cell count in the young dogs is slightly higher than that in the adult dogs (12,165 and 11,467 per cu. mm., resp.). The av. differential counts for both groups are given. Howard W. Robinson

Aneurin excretion after injection of cocarboxylase. H. G. K. Westenbrink and J. Goudsmit. *Arch. néerland. physiol.* **24**, 305–9(1939).—The rat kidney does not excrete cocarboxylase. Even when 250 γ of cocarboxylase is injected into a 150-g. rat all the vitamin B_1 excreted is in the form of free thiamine. The same type of excretion probably holds for all mammals. Felix Saunders

Antigonadotropic hormones in normal human blood serum. Marvel-Dare Fellows. *Endocrinology* **26**, 369–76 (1940).—Normal human blood serum taken during various stages of the menstrual cycle and injected into immature female white rats failed to produce any activation or inhibition of the growth of the ovaries. An aq. ext. of human anterior lobe powder exerted a marked gonadotropic effect when given in small doses over a period of several days. The best response was obtained with 0.8 cc. of the ext. when given in 8 equal doses injected twice daily. There is no evidence that human blood serum normally contains a substance which exerts an inhibitory effect on human anterior pituitary ext. when both are injected simultaneously. Felix Saunders

Effects of testosterone propionate on epiphyseal closure, sodium and chloride balance and on sperm counts. E. Perry McCullagh and F. J. McGurl. *Endocrinology* **26**, 377–84(1940).—The findings of Kenyon, *et al.* (*C. A.* **32**, 7987[6]) were confirmed. The demonstration of an increase in the rate of epiphyseal maturity beyond normal suggests that dwarfing might be produced by large doses of testosterone. Sperm production decreased. Felix Saunders

Effect of testosterone on the monkey uterus and the administration of steroidal hormones in the form of Deansly-Parkes pellets. Carl G. Hartman. *Endocrinology* **26**, 449–71(1940).—The absorption of a properly made pellet can be regulated so as to approach the physiol. The method is especially applicable where small amts. of hormone over long periods of time are desired. In monkeys a progestational endometrium was never attained with testosterone alone or in combination with estrogens. No evidence was found for any antagonistic action of testosterone either to estrogen or progesterone when concomitantly injected with one or both of these ovarian hormones. The action of testosterone on the sex skin is distinctly estrogenic, i. e., antagonistic to progesterone. Testosterone is able to maintain an endometrium already built up by estrogen. Felix Saunders

Effect of the thyrotropic principle of the anterior pituitary on the thyroid of the undernourished guinea pig. D. J. Stephens. *Endocrinology* **26**, 485–92(1940).—The use of the undernourished guinea pig may increase the sensitivity of present methods for the detection and estn. of small amts. of the thyrotropic hypophyseal principle. Felix Saunders

Effect of normal male urine extract on immature female cats. W. F. Starkey and J. H. Leathem. *Endocrinology* **26**, 499–502(1940).—Injection of an ext. of male urine into immature female cats increases ovarian wt. as much as 8-fold. After treatment for 11 days only follicle stimulation is observed but extended treatment results in the formation of corpora lutea atretica. An estrus or pseudopregnant endometrium develops in assocn. with the state of the ovary. Felix Saunders

Liver growth in rats treated with anterior pituitary growth hormone. Milton Lee and Wm. Freeman. *Endocrinology* **26**, 493–8(1940).—The av. liver wt., ratio of liver wt. to body wt. and total no. of hepatic cells were significantly greater in rats treated with anterior pituitary growth ext. as compared with controls. The no. of cells per g. of fresh liver was the same in the 2 groups. Under the influence of the growth hormone the liver responds with a true hyperplasia with all the structural elements participating equally. Felix Saunders

Spermatogenesis in rats. Eugene Cutuly and Elizabeth C. Cutuly. *Endocrinology* **26**, 503–7(1940).—Spermatogenesis was induced in 34-day-old hypophysectomized rats but not in 29-day-old hypophysectomized animals injected with testosterone propionate. F. S.

Effect of male sex hormone on the developing ovaries of young fowls. E. H. Herrick and Charles H. Lockhart. *Endocrinology* **26**, 508–10(1940).—Young female chicks that receive small doses of testosterone propionate (2.5 mg.) have ovaries slightly smaller than the controls and follicular development is somewhat less than in the controls. Felix Saunders

Precocious copulatory activity induced in male rats by subcutaneous injections of testosterone propionate. Calvin P. Stone. *Endocrinology* **26**, 511–15(1940); cf. *C. A.* **33**, 2575[9].—By daily injections of 0.62 mg. of testosterone propionate into rats on and after the ages of 22–26 days the median age of first copulation was set ahead of that of controls by about 20 days. F. S.

Recovery of testes after androgen-induced inhibition. R. R. Greene and M. W. Burrill. *Endocrinology* **26**, 516–18(1940).—Low doses of testosterone propionate (0.1 mg. daily for 20 days) inhibits testicular growth in young rats. Seven to 10 months after treatment the testes are normal. Felix Saunders

Preparation of the gonadotropic hormone from the anterior pituitary of the sow. C. Arthur Elden and M.-D. Fellows Nutting. *Endocrinology* **26**, 526–7(1940).—A method of prepg. a purified gonadotropic hormone from the anterior lobe of the pituitary of the sow by pptn. with dioxane at pH 7.1–7.3 is described. One unit of the hormone thus prepd. weighs 0.56 mg. F. S.

Hormone content of human tissues in pregnancy. Frederic Parker, Jr., and Benjamin Tenney, Jr. *Endocrinology* **26**, 527–9(1940).—Prolan is found in placenta, maternal blood and urine in approx. equal amts. It is not found in fetal organs, fetal blood or amniotic fluid in normal pregnancy. It is not found in maternal organs during pregnancy except in the uterus. Felix Saunders

Estrogens of the fowl. H. W. Marlow and Dan Richert. *Endocrinology* **26**, 531–4(1940).—The yolk from freshly laid eggs contains 5 rat units of estrogenic material per kg. of yolk. Contents of immature ova greater than 10 mm. in diam. contain 44 units per kg. The follicular membranes contain 6 units per kg. of whole immature ova. Whole ovaries contg. follicles less than 6 mm. in diam. contain 37 units per kg. Felix Saunders

Relative effects of progesterone and testosterone propionate upon ovipositor lengthening in the female bitterling. Israel S. Kleiner. *Endocrinology* **26**, 534–5(1940).—Although progesterone causes lengthening of the ovipositor of the female bitterling in greater diln. than does testosterone propionate, this effect is relatively slight as compared with that of the male hormone. Moreover, the max. progesterone action takes place during the first 6–8 hrs. while that of testosterone is observed only in 24–72 hrs. Felix Saunders

Emptying time of the human stomach after administration of progestin. Clark K. Sleeth and Edward J. Van Liere. *Endocrinology* **26**, 535–6(1940).—One Corner unit of progestin (injected intramuscularly) had no effect on the gastric emptying time as detd. fluoroscopically in 4 healthy young males. Felix Saunders

Pituitary mitotic changes after the administration of estrogen and after ovariectomy. W. C. Kuzell and W. C. Cutting. *Endocrinology* **26**, 537–8(1940).—Ovariectomized rats show no consistent evidence of pituitary growth, as indicated by practically unchanged mitotic reactions to colchicine. On the other hand, estrogen-injected rats show a considerable and prolonged pituitary growth. Felix Saunders

Isometric length-tension diagram of isolated skeletal muscle fibers of the frog. Robert W. Ramsey and Sibyl F. Street. *J. Cellular Comp. Physiol.* **15**, 11–34(1940).—The equil. resting tension of stretched single striated muscle fibers of the frog is due to the sarcolemma but the muscle substance itself behaves plastically. F. S.

Conditions determining the selective secretion of dyes

by the isolated frog kidney. Rudolf Höber and Pristilla M. Briscoe-Woolley. *J. Cellular Comp. Physiol.* **15**, 35–46(1940).—The relation between configuration of dye mols. and selective secretion by the proximal tubules of isolated Ringer-perfused frog kidney was detd. Three main groups of dyes were investigated: monoazo, disazo and triphenylmethane. The triphenylmethane dyes, in general, fail to undergo the secretory transport, whereas the azo dyes reappear in the secretion in a concn. higher than the initial one, provided the sulfonate groups of the mol. are arranged in the proper way. Location of the sulfonates on one-half of the elongated, bilateral mols. enables the dye to pass, whereas secretion is prevented if the sulfonic groups are located at the 2 ends of the mol. The formation of a sort of Langmuir film on the cell surface may be the first step in the complex process of secretory transport, the organophilic end of the mol. being attached to the cell surface, the hydrophilic end anchoring at the aq. surroundings. Lipoid soly. favors secretion but is not indispensable. Felix Saunders

Swelling of sexual skin in Rhesus monkeys. A. G Ogston, J. St. L. Philipot and S. Zuckerman. *J. Endocrinol.* **1**, 231–8(1939).—The serum protein, mucoprotein, nonprotein N and chloride content of sexual skin exudate and of serum were compared at different stages of swelling Sexual skin exudate can be regarded as the tissue fluid of the skin when it is swollen. The compn. of the exudate does not vary much with the phase of swelling. The most marked differences from serum are the presence of mucoprotein, the lower concn. of serum-like proteins, higher nonprotein N and higher total chloride. F. S.

Species variation in thyrotropic, gonadotropic and prolactin activities of the anterior hypophyseal tissue. M. R. A. Chance, I. W. Rowlands and F. G. Young. *J. Endocrinol.* **1**, 239 60(1939).—The amts. of thyrotropin, gonadotropin and prolactin in Me_2CO-desiccated anterior pituitary tissue from man, horse, sheep, pig and ox were detd. The greatest amts. of all 3 activities are in pituitaries from pig, man and sheep. Gonadotropic activity, assayed by ability to induce ovulation in the estrus rabbit, is present to a substantial extent in the pituitary tissue from all 5 species examd., but when assayed by capacity to cause ovarian growth in the immature rat, the pituitary glands of man and horse are found to contain large amts., whereas those of the other animals have only slight activity. The van Dyke acid-buffer method (van Dyke and Wallen-Lawrence, *C. A.* **26**, 1968) and the Bates-Riddle alk. aq. alc. method (*C. A.* **30**, 3490[9]) are both satisfactory for the prepn. of exts. with thyrotropic activity. The B.-R. method is satisfactory for the prepn. and purification of prolactin. Aq. alk. extn. or extn. with acid buffer is a satisfactory procedure for the prepn. of exts. with gonadotropic activity. Alk. aq. alc. is greatly inferior to simple aq. alkali for the extn. of gonadotropic substance (ovarian growth assay) from horse pituitary tissue. Felix Saunders

Effects of estrogen and androgen injections on reproductive organs in male rats and mice. Ralph Harsh, M. D. Overholser and L. J. Wells. *J. Endocrinol.* **1**, 261 7 (1939).—Estrogen induces stratified squamous epithelium in ducts of Cowper's glands and seminal vesicles, and in anterior prostates and ducts of immature rats and in seminal vesicle ducts of adult rats. In mice, estrogen administration causes penis extrusion, bladder dilatation, thickening of the submucosa of the intraprostatic part of the vasa deferentia, metaplastic stratification of epithelium in seminal vesicle ducts and anterior prostate and ducts. Testosterone prevents metaplasia in anterior prostates but does not completely suppress other pathol. changes. Felix Saunders

Inadequacy of the vaginal smear in the rat as an index of ovarian dysfunction caused by diet. S. C. Freed, O. Hechter and Samuel Soskin. *J. Endocrinol.* **1**, 268–74 (1939); cf. *Am. J. Physiol.* **123**, 70(1938).—The vaginal mucosa in the rat is not an accurate indicator of complete ovarian function. Under certain dietary conditions normal rats develop vaginal estrus in the presence of uterine diestrus and ovarian atrophy. The rat ovary may elaborate several distinct factors or partial estrogens. The effects of these partial estrogens differ qualitatively and the complete estrus phenomenon is a composite of the several partial effects. Felix Saunders

Uterus masculinus of the rabbit and its reactions to androgens and estrogens. Ruth Deanesly. *J. Endocrinol.* **1**, 300–6(1939).—Small or large quantities of estrogens cause conspicuous growth of the uterus masculinus but the epithelium can only be restored to normal by the administration of Me testosterone or testosterone in relatively large amts. (25–70 mg. in 40 days) transplanted subcutaneously. Felix Saunders

Modification of the effectiveness of gonadotropic extracts. Ruth Deanesly. *J. Endocrinol.* **1**, 307–22(1939).—Groups of immature female rats were used for testing various gonadotropic exts. A study was made of the extent to which the effectiveness of given amts. can be modified by varying the no. of injections, delaying absorption by addn. of inert substances and combining 2 different exts. Felix Saunders

Effect of route of administration on the multiple activities of testosterone and methyltestosterone in different species. C. W. Emmens and A. S. Parkes. *J. Endocrinol.* **1**, 323–31(1939).—Testosterone is much less active by mouth than by injection in tests for androgenic activity in the capon and castrated male rat, in metrotropic tests on spayed rats or immature rabbits and in tests for progesterone-like activity in rabbits. Methyltestosterone, however, is almost as active by mouth as by injection in causing progestational proliferation in rabbits and has a relatively greater activity by mouth in the other tests than has testosterone. When given orally instead of by injection to rats its androgenic activity decreases much less than its power of causing an increase in uterine wt. Methyltestosterone is more potent than testosterone as an androgen in rats, but less potent in capons; it is more potent in the progestational tests whichever route of administration is considered. The 2 substances are about equally active in causing uterine growth in spayed rats and immature rabbits. Felix Saunders

Biological properties of anhydrohydroxyprogesterone (ethinyltestosterone). C. W. Emmens and A. S. Parkes *J. Endocrinol.* **1**, 332–8(1939); cf. *C. A.* **33**, 6938[8]. In the capon comb-growth test, anhydrohydroxyprogesterone (I) shows weak androgenic activity but is equally active by mouth and by injection, having about $^1/_{600}$ the activity of injected testosterone. I, when given in propylene glycol, is equally active by mouth and injection in producing progestational proliferation in rabbits, having about 0.1 the potency of injected progesterone. I produces growth of the uterus of the spayed rat, without previous treatment with estrogen. The effects are very similar to those produced by progesterone in the uterus already primed with estrone. It appears to be more effectively progestational when given orally, although of equal potency by mouth and by injection in increasing uterine wt. I is more active by injection than by mouth in causing cornification of the vagina of the spayed rat or mouse and vaginal opening in the spayed rat. In addn. to its high oral activity in the different tests, I seems to be the only compd. so far described which has progesterone-like, metrotropic, androgenic and estrogenic properties. Felix Saunders

Anterior pituitary fractions and carbohydrate metabolism. I. The preparation and properties of diabetogenic extracts. F. G. Young. *J. Endocrinol.* **1**, 339–55(1939); cf. *C. A.* **34**, 2041[2].—By fractionation at 0° with $(NH_4)_2SO_4$, globulin, pseudoglobulin, euglobulin and albumin fractions were prepd. from ox anterior pituitary tissue. Only the globulin and pseudoglobulin fractions are diabetogenic when injected into normal dogs. The diabetogenic fractions possess thyrotropic, gonadotropic and glucotropic activities, but prepns. with such activities are not necessarily diabetogenic. The gonadotropic, thyrotropic and glucotropic substances are not diabetogenic per se in the intact dog. Exts. with diabetogenic activity possess greater growth-promoting activity than nondiabetogenic fractions. Some chem. properties

of active fractions are described. Dogs made temporarily diabetic by treatment with anterior lobe exts. have less muscle glycogen, about the same amt. of liver glycogen and more liver fat than do normal dogs under similar conditions. An *app.* for continuous filtration is described. F. S.

Rhythmic processes in the living world. A. Jores. *Kolloid-Z.* **89**, 163–4(1939).—The activity of the heart, peristalsis of the intestine, motion of cilia, etc., are examples of rhythmic processes in living organisms. These processes are influenced by many factors such as time, light, temp., barometric pressure or aeration. F. S.

Argument for chemical mediation of nerve impulses. Walter B. Cannon. *Science* **90**, 521–7(1939).—Chem. *vs.* elec. mediation is discussed. Felix Saunders

Mechanism of the biological citric acid synthesis. Nnlo Hallman and P. E. Simola. *Science* **90**, 594–5 (1939).—When 15 mg. of Na pyruvate is incubated with 20 g. minced heart muscle 1.2 mg. citrate is formed, when 30 mg. of Na malate is used 3.1 mg. of citrate is formed, but when the pyruvate and malate are incubated together 25.0 mg. of citrate is formed. The effects of oxaloacetic acid and fumaric acid in heart muscle are equal and distinctly less than that of malic acid. In other tissues oxaloacetic acid produces the best effects. When boiled tissue is used no synthesis of citric acid can be demonstrated. The effect of phosphopyruvic acid is distinctly less than that of pyruvic acid. In heart muscle pyruvic acid is transformed *via* citric acid to a large extent. F. S.

Pseudomethemoglobin and its reaction with carbon monoxide reduction. Georg Barkan and Otto Schales. *Science* **90**, 616(1939); cf. *C. A.* **32**, 5499⁷.—Other workers have found that in normal blood and in oxyhemoglobin solns there are hemoglobin-like compds. which combine with CO only after previous reduction. F. S.

Electrophoretic study of pituitary lactogenic hormone. Choh Hao Li, Wm. R. Lyons and Herbert M. Evans. *Science* **90**, 622–3(1939). A prepn. which caused lactation in normal, virgin, postestrus guinea pigs showed little or no signs of a contaminant when submitted to electrophoresis. The isoelec. point is at pH 5.70. F. S.

Fate of plasma prothrombin. Wm. DeW. Andrus, Jere W. Lord, Jr. and Joseph T. Kauer. *Science* **91**, 18–50(1940). The level of plasma prothrombin in the circulating blood is decreased during its passage through the pulmonary capillaries. The difference is about 10%. In samples of blood taken from the arterial and venous supply of the head, liver, spleen, intestine, kidney and hind limbs, no significant difference in plasma prothrombin levels was found. The loss is not concerned with oxygenation. The prothrombin may be assocd. with the formation of blood platelets. Felix Saunders

State of the inorganic components of human red blood cells. Rebecca Z. Solomon, Pauline M. Hald and John P. Peters. *J. Biol. Chem.* **132**, 723–38(1940).—Hemolysis of blood by repeated freezing or by addn. of saponin decreases the rate of glycolysis and hydrolysis of phosphate esters. When hemolyzed blood was ultrafiltered through cellophane, Na, K and phosphates were not distributed between the H_2O of substrate and ultrafiltrate as if they were restrained only by the Gibbs-Donnan equil. The concn. of inorg. phosphate was higher in the substrate. K was distributed according to the Gibbs-Donnan equil., but Na was more uniformly distributed. In blood hemolyzed by freezing the acid-sol. org. P remained unchanged and nonfiltrable after 18 hrs. at 7°, but was largely changed to inorg. phosphate at 37° and the residual org. P was evenly distributed. In saponin-hemolyzed blood at 7° the org. P was unchanged and evenly distributed. In intact blood at 7° the org. P remained unchanged and nonfiltrable, and at 37° it was largely changed to inorg. phosphate, the residual org. P being nonfiltrable. The implications with respect to the state of these solutes in red blood cells are discussed. D. S. Searle

Origin of urogastrone. C. U. Culmer, J. S. Gray, J. L. Adkison and A. C. Ivy. *Science* **91**, 147–8(1940).—The ingestion of a high-fat diet by dogs augments the urinary excretion of urogastrone (I). The urine of fasting dogs contains I. I disappears from the urine after surgical removal of the pyloric antrum and small intestine. I may represent excreted enterogastrone. D. S. Searle

Dental enamel and fluorine. Robert Klement. *Umschau* **42**, 488–9(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 299.—The hardness of dental enamel is attributed, not to the F (0.03%) it contains, but to hydroxyapatite. The high content (3%) of F in fossil teeth and bone is due to replacement of (OH) by F from the ground water; this forms fluorapatite. C. A. Silberrad

Study of uterine movements through abdominal windows. III. Castrated and young rabbits, and the effect of the ovarian hormone on uterine movements. Tadatake Yazima (Iino). *J. Chosen Med. Assoc.* **29**, 2221–55 (German abstr., 142–3)(1939).—The uterus of castrated animals loses its characteristic movements—peristaltic, anti-peristaltic, pendular and general contractile. When 100 units of ova-hormone are given twice, the characteristic movements return, lasting 5–6 days. The uterus of 2-month-old rabbits whose ovaries contain no follicles shows no characteristic movement, but an injection of 100 units of the hormone produce peristaltic and anti-peristaltic movements, but no pendular or general contractile motions. S. Tashiro

Adrenal cortex and phosphorylation of vitamin B_1. S. Ochoa and R. J. Rossiter. *J. Physiol.* **97**, 1–2P(1940); cf. *C. A.* **32**, 9204⁴.—Even in extreme adrenal cortical insufficiency, direct detns. of cocarboxylase offer no evidence for the theory that the adrenal cortical hormone is necessary for the phosphorylation of vitamin B_1. E. D. Walter

The primary acidity of the gastric juice. Torsten Teorell. *J. Physiol* **97**, 308–15(1940).—A new method is outlined for a direct detn. of the primary acidity. It is based on observations that the rate of acidity reduction is proportional to the H-ion concn. of the stomach contents. The essential part of the technique is the utilization of the acid buffering power of glycocoll. On cats stimulated with histamine, reliable values of the primary acidity were obtained only at high rates of secretion. The av. value was 208 ± 6 millinormal, but there are reasons for believing that this value is slightly too high. Possibilities of an "intraglandular" acidity regulation are discussed. E. D. Walter

The oxygen supply of the fetal brain of the sheep and the effect of asphyxia on fetal respiratory movement. J. Barcroft, D. H. Barron, A. T. Cowie and P. H. Forsham. *J. Physiol.* **97**, 338–46(1940); cf. *C. A.* **33**, 4626⁷. E. D. Walter

Oxygen in the blood of the umbilical vessels of the sheep. J. Barcroft, J. A. Kennedy and M. F. Mason. *J. Physiol.* **97**, 347–56(1940); cf. preceding abstr. E. D. Walter

Cozymase in adrenalectomized rats. John Runnström, Erik Sperber and Ernst Bárány. *Nature* **145**, 106(1940). —Expts. failed to show any difference between adrenalectomized and control rats in the cozymase contents of heart, liver, muscle and kidney. E. D. Walter

G - PATHOLOGY

Blood changes in pain. M. M. Gubergrits. *Acta med. U. R. S. S.* **1**, 136–46(1938).—In 81 patients suffering from paroxysmal pain, and in 100 women in labor, the blood ketones (mainly β-hydroxybutyric acid) were con-

siderably increased during the paroxysms. In patients suffering from headache due to concussions such changes were not found. In 30 of these patients no changes were found in blood Ca, K, Na, O or CO_2. The ratio K:Ca was low in every case. In expts. on 2 cats and 12 dogs in which the sciatic nerve was stimulated, similar results were obtained. B. C. P. A. 1

Value of the "oxidation-reduction potential" [in schizophrenia]. M. Serezhskiĭ. *Acta med. U. R. S. S.* 2, 375–94(1938); cf. *C. A.* **33**, 9429[6]. —The oxidation-reduction potential is of great value in differential diagnosis of organic and functional diseases. Over 1000 cases of schizophrenia were examd.; the results are given in diagrams. B. C. P. A. 2

Hyperemesis gravidarum. E. Schjott-Rivers. *Acta Obstet. Gynecol. Scand.* **18**, Suppl. 1, 1–218(1938).—The history and theories of etiology of hyperemesis gravidarum are extensively reviewed. Addnl. clinical observations have been recorded. Urinary Cl concn. in untreated cases was very low and was related partly to inanition and partly to Cl loss from vomiting. Blood Cl varied greatly, but hypochloremia when present was considered secondary to the vomiting, and was not assigned any particular pathogenetic importance. An increase in nonprotein N was rarely found and was assocd. with signs of kidney lesion. There was no relationship between nonprotein-N values and symptoms of intoxication. 80% of patients with hyperemesis had urobilinuria. As an indication of liver damage the urobilinuria was not as reliable as bilirubinemia. Following a test meal most cases had achlorhydria; this was thought not to be related to the hypochloremia. The clinical observations include 6 patients where visual disturbances were encountered and 3 patients who developed nerve lesions. Detailed case reports and post-mortem findings in 5 cases are described. B. C. P. A. 3

Creatinuria in dementia precox. R. Stora and P. Tcherneakofsky. *Ann. méd.-psychol.* **2**, 726–37(1938). Of 20 patients with dementia precox, 8 of which were catatonic, 14 showed hypercreatinuria with no close relationship to the catatonic state or to endocrine function. B. C. P. A. 4

Dermatomyositis with scleroderma and calcinosis. J. H. Talbott, E. A. Gall, W. V. Consolazio and F. S. Coombs. *Arch. Internal Med.* **63**, 476–96(1939). Metabolic and pathol. studies in a case are reported. B. C. P. A. 5

Hyperthyroidism and hypertension. J. D. Bisgard. *Arch. Internal Med.* **63**, 497–503(1939).—8% of 265 patients with hyperthyroidism had also essential hypertension, some being pre-established, others provoked by the hyperthyroidism. B. C. P. A. 6

Pharmacological study of myotonia. Alfredo Lanari. *Arch. intern. pharmacodynamie* **61**, 360–9(1939); cf. *C. A.* **33**, 1032[2], 1039[9]. Subcutaneous intravenous and brachial intra-arterial injection of drugs was practised in human subjects with myotonia and progressive muscular atrophy. Acetylcholine caused contracture in myotonia. Prostigmine aggravated myotonia. Adrenaline, with which precautions were taken to prevent its rapid passage to veins, improved the myotonic condition without affecting atrophied muscles. Atropine had no effect. $MgSO_4$ and quinine caused temporary improvement. Alcohol and Na lactate were inactive. B. C. P. A. 7

Ketosis in circulatory insufficiency. I. B. Shur. *Conf. Insuff. Circ.* **1938**, 207–21.—Ketosis appears in advanced circulatory insufficiency, the concn. of ketone compds. in blood and urine being proportional to the severity of the condition; this relationship does not hold in cases presenting severe liver or lung disabilities, or in the dystrophic stage. No parallelism exists between ketonemia and ketonuria. Ketonuria is due chiefly to acetoacetic and β-hydroxybutyric acids, acetone being excreted chiefly by the lungs. A fall in the acetone content of expired air and of the urine is an unfavorable prognostic sign. Exercise causes prolonged ketonemia in cardiac insufficiency. Injections of glucose and insulin may be beneficial in the early, but are harmful in the late stages of circulatory insufficiency. B. C. P. A. 8

Gastric disorders in renal disease. W. Henning. *Deut. Z. VerdauKr. Stoffw.* **1**, 250–7(1939).—21% of patients with renal disease showed gastric symptoms. Patients with raised blood urea and nonprotein N developed anacidity; hyperacidity was seen in ten patients with normal blood urea. B. C. P. A. 9

Chronic superficial gastritis. J. Bank and J. F. Renshaw. *J. Am. Med. Assoc.* **112**, 214–17(1939).—In 50 patients with chronic superficial gastritis diagnosed by means of the gastroscope abnormal secretion of acid was present in 80%. Hyperacidity was present in 50% and anacidity in 26%. A delay in the emptying time of the stomach was also observed, but in 65 patients with peptic ulcer the incidence of gastritis was not dependent on the presence of gastric retention. B. C. P. A. 10

Pathogenesis of paroxysmal paralysis of the extremities. K. Tuzi. *Klin. Wochschr.* **18**, 320–4(1939).—8 of 11 cases were complicated by thyrotoxicosis. Carbohydrate meals or thyroid medication caused attacks; prolonged insulin treatment was beneficial. Biochem. examn. of 3 patients showed a sudden decrease in O consumption in the early and a rise in the later stages of the paralysis. Serum lactic acid was raised. B. C. P. A. 11

Mechanism of renal excretion of glucose. P. Govaerto *Bull. acad. roy. méd. belg.* **3**, 491–509(1938). A review. C. L. B. 12

Poultry diseases, their prevention and control. L. D. Bushnell and M. J. Twichaus. *Kansas Agr. Expt. Sta., Bull.* **284**, 125 pp. (1939).—General. Chem. and biol. control methods are outlined for each disease. Dosage tables for chickens are included. C. R. Fellers 13

Quantitative study of tumor growth in mice treated with extracts of adrenal cortex. N. Dobrovolskaia-Zavadskaia and P. Zephiroff. *Compt. rend. soc. biol.* **132**, 352–5 (1939).—Repeated injections of aq. ext. of adrenal cortex retarded the growth of various types of cancer. L. E. Gilson 14

Rapid production of [Vipera aspis] antiserum in rabbits by means of anavenom. F. Cesari and Paul Boquet. *Compt. rend. soc. biol.* **132**, 363–5(1939). L. E. G. 15

Spindle cell sarcomas observed in mice given injections of various substances over a long period. A. Lacassagne. *Compt. rend. soc. biol.* **132**, 365–8(1939). In mice of both sexes repeated subcutaneous injections of various male and female sex hormone prepns. sometimes produced subcutaneous spindle cell sarcomas after 300 days or more. The repeated traumatism may have been partly responsible. L. E. Gilson 16

[Increase in] alexin during leucemia. M. L. Chevrel and J. Ranque. *Compt. rend. soc. biol.* **132**, 526–8(1939). L. E. Gilson 17

Demonstration of the toxin of botulism in blood and tissues. Harry J. Schneider and Roy Fisk. *J. Am. Med. Assoc.* **113**, 2299–300(1939). Toxin was demonstrated, by mouse injection, in the saline liver ext. from 4 fatal cases of botulism and in the blood of 1 patient. F. P. Griffiths 18

Preliminary studies on the preparation of tetanus toxoid and antitetanic serum. Juan D. Generoso. *Philippine J. Animal Ind.* **5**, 229–46(1938). Tetanus toxin treated with 0.3 to 0.4% formalin and incubated at 37.5° for 1 month was converted into toxoid. The antigenic efficiency of the toxoid was increased by the addn. of 0.2 to 0.4% Al K sulfate. Toxoid dissolved in 0.5% Na citrate soln. was less potent than the simple broth toxoid with 0.2 to 0.4% Al K sulfate. One injection of a potent toxoid may give sufficient protection against natural tetanus infection, but 2 injections with an interval of 3 weeks to 1 month or more give much higher protection. Large Filipino horses were used for the production of antitetanic serum. A potent toxoid can be used for the 1st 2 injections instead of a toxin-antitoxin mixt. **Studies on the preparation of tetanus toxoid and antitetanic serum.** *Ibid.* **6**, 209–12(1939). A potent toxoid can be prepd. from toxin with a titer of 1 cc. of 1–5000 diln. as the M. F. D. (the least amt. of toxin required to kill a 340–360-g. guinea pig of tetanus within 96 hrs. after injection). Toxoid contg. 2% Al K sulfate produced higher immunity 19

than that contg. only 0.2%. One injection of 10 cc. of the former produced an immunity equiv. to 0.1 American unit per cc. of the serum of a horse injected, and a 2nd injection given 20 to 39 days later increased this titer by ten times. John O. Hardesty

Systemic disturbances in severe burns and their treatment. J. Russell Elkinton. *Bull. Ayer Clin. Lab. Penna. Hosp.* **3**, 279–91(1939).—Four cases of severe burns in man were characterized by hemoconcn. and loss of plasma protein which were overcome by plasma transfusion; 3 cases also showed a definite toxic period unassocd. with these changes. 26 references. J. S. Hepburn

Inhibitory power of human serum against digitonin (saponin) hemolysis. David L. Earley. *Bull. Ayer Clin. Lab. Penna. Hosp.* **3**, 331–4(1939).—The power of the serum to inhibit hemolysis by digitonin was distinctly greater in normal persons than in diseased persons. This inhibition did not depend upon the cholesterol content of the serum. Joseph S. Hepburn

Role of sugar in the etiology of dental caries. Philip Jay. *J. Am. Dental Assoc.* **27**, 393–6(1940).—Control of carbohydrate consumption is the only dietary procedure thus far demonstrated by which dental caries can be controlled; 12 references. Joseph S. Hepburn

Experimental dental caries. IV. Fluorine and its relation to dental caries. Gerald J. Cox, Margaret C. Matuschak, Sara F. Dixon, Mary L. Dodds and W. E. Walker. *J. Dental Research* **18**, 481–90(1939); cf. *C. A.* **34**, 1072[3].—The presence, in the ration of rats, of an optimum amt. of fluoride during tooth formation lowers the incidence of dental caries. 33 references.

Joseph S. Hepburn

Factors influencing the infectivity of fowl tumors. F. R. Selbie and J. McIntosh. *Brit. J. Exptl. Path.* **20**, 443–51(1939).—The filterability of chemically induced fowl tumors depends to a great extent on the virulence of the tumors, and, conversely, the virulence of such a tumor depends on the activity of the virus. The virulence of such a tumor, and therefore the activity of the virus, can be increased by methods designed to discourage cellular transmission. Suspensions of filterable and most nonfilterable fowl tumors can be increased in infectivity by proteolytic digestion. Repeated freezing and thawing by the technique described increases the infectivity of suspensions of the filterable fowl tumors, but annuls the infectivity of the nonfilterable tumors. H. F. Holmes

Neutralizing and complement-fixing properties of antiserums produced by fractionated extracts of a nonfilterable dibenzanthracene fowl sarcoma. L. Foulds and L. Dmochowski. *Brit. J. Exptl. Path.* **20**, 458–65(1939).—The serum of a rabbit, which received injections of sand and paper pulp and Berkefeld filtrates of the nonfilterable dibenzanthracene fowl sarcoma RFD 2, neutralized filtrates of Rous sarcoma No. 1; the neutralizing power was not abolished by absorption with normal fowl tissues. The serums of rabbits which received filtrates of the same tumor prepd. by means of collodion membranes having av. pore diams. of 0.8 μ or 0.14 μ, resp., had weak neutralizing properties which were abolished by absorption with normal fowl tissues. The antigen which elicited neutralizing antibodies, other than "fowl" antibodies, was apparently larger than the infective agent of Rous sarcoma. Complement-fixation tests indicated that RFD 2 and Rous sarcoma contained 2 antigens which were not demonstrated in normal fowl tissues; one antigen was comparable in size with the infective agent of Rous sarcoma and the other was smaller. The relationship between the neutralizing and the complement-fixing antibodies was not established. Harriet F. Holmes

A complement-fixing antigen common to filterable and nonfilterable tumors of fowls. L. Dmochowski and R. Knox. *Brit. J. Exptl. Path.* **20**, 466–72(1939).—Serum prepd. by immunizing a rabbit with 0.8 μ-membrane filtrates of the nonfilterable tumor RFD 2 gives complement fixation with active filtrates of Rous and Mill Hill 2 tumors and of fowl- and duck-grown Fujinami tumors. The reaction has a practical value in making it possible to predict the relative activities of different filtrates before the results of activity tests are available. Since RFD 2 filtrates and heat-inactivated Rous filtrates also give a complement-fixation reaction, it is evident that both filterable and nonfilterable tumors share a common antigenic factor which is not species-specific. Harriet F. Holmes

Cellular absorption of carcinogenic hydrocarbons (preliminary report). A. Graffi. *Z. Krebsforsch.* **49**, 477–95(1939).—Glycerol solns. were made of several cancerogenic and noncancerogenic hydrocarbons by adding the dry or melted hydrocarbon to water-free glycerol and heating. Serum was added to the hot soln., at first drop by drop. Any desired dilns. can be made later without pptn. of the hydrocarbons. All the solns. used showed fluorescence under ultraviolet light. These solns. were mixed with ascitic fluid from mouse carcinoma contg. living carcinoma cells and exam'd. with a fluorescent microscope. With benzopyrene, methylcholanthrene and dibenzanthracene there was a marked dark-blue fluorescence of the lipoid granules in the cells and a slighter fluorescence of the protoplasm. The nucleus showed no fluorescence except occasionally a faint shimmer in the nucleolus. Dibenzanthracene gave less fluorescence than either benzopyrene or methylcholanthrene. The noncancerogenic pyrene gave similar results, though the fluorescence was green. With the noncarcinogenic anthracene the fluorescence was blue but much less extensive and appeared only after an hr. or more and some cells failed to show any fluorescence. 2,3-Benzanthracene which is noncarcinogenic gave a yellowish fluorescence and only slightly affected the cells with a yellow or yellow-green fluorescence. Expts. were made with various other living cells, and also expts. *in vivo* by intraperitoneal injection in tumor mice with ascites with similar results. It would seem that only those substances are carcinogenic that are taken up by living cells in a relatively high concn. and show a blue fluorescence when so absorbed.

Harriet F. Holmes

Experimental production of tumors of the salivary glands. E. Benecke and J. Schröder. *Z. Krebsforsch.* **49**, 505–14(1939).—Injections were made of 3,4-benzopyrene in varying amts. into the parotid gland of rats and mice. Up to date 2 polymorphic spindle or round cell sarcomas have been formed in the rats and 4 in the mice. One mouse dying the 4th month after the injection had no macroscopic tumor, but histologic examn. showed a keratinizing squamous carcinoma. In neither rats nor mice were there found any mixed tumors analogous to the mixed tumors of the human parotid gland. H. F. H.

Some compounds chemotherapeutically active on implanted tumors. C. Dittmar. *Z. Krebsforsch.* **49**, 515–24(1939). Bromo- and iodo-acetic acids and their derivs. markedly inhibit tumor glucolysis and have a slight effect on the growth of tumors in mice, but are not available for therapeutic use on account of their great toxicity. The halo dicarboxylic acids, bromosuccinic acid and bromomalonic acid, are less toxic and more suitable for use. Some chaulmoogra compds. have therapeutic value, especially chaulmoogrylzephirol. Colchicine inhibits tumor growth but is very toxic. Less toxic derivs. as colchicein and oxycolcheine are without effect. Garlic contains a volatile substance that injures tumor cells and bacteria and which seems to be diallyl sulfide. The active group is the allyl group, for diethyl sulfide is without effect on tumor growth. Some bactericidal compds. such as *p,p'*-diamidodiphenyl sulfoxide and algamidol inhibit tumor growth. Heptylaldehyde liquefies spontaneous tumors (carcinoma of the mammary gland) in mice. This is probably the result of the capillary injury that it produces. It also inhibits the growth of implanted tumors and the unsatd. aldehyde citral is even more effective. Harriet F. Holmes

Polarographic cancer reactions and the measurement of the sulfhydryl activity of serums toward methylglyoxalase. VII. P. Meyer-Heck. *Z. Krebsforsch.* **49**, 560–72(1939).—The most important polarographic cancer reactions were studied and tested on 242 serums. The method of Waldschmidt-Leitz (*C. A.* **32**, 6725[8]) seemed to be the most reliable but it was far from specific. Thirteen or 17% of the 77 carcinoma cases were neg. and these were mainly squa-

mous and scirrhous carcinomas and carcinoma of the rectum. The serums of healthy individuals all gave a normal reaction. Control cases with diseases without marked inflammation gave a pos. reaction of 11% and cases with inflammatory diseases a pos. reaction of 65%. The entire group of 164 controls gave a false reaction of 36.4%. The albumin content of the serum was always detd. and a relation between the polarographic values and the albumin content could not always be demonstrated, nor did the speed of sedimentation of the red blood corpuscles always agree with the polarographic findings. A new method of Waldschmidt-Leitz and K. Mayer is at present under trial and gives hope of an increase in specificity. The SH-activity of the serum toward methylglyoxalase was tried on 70 serums, but the method proved to be too involved and unreliable for a cancer reaction. H. F. H.

Carcinogenic benzopyrene obtained from tobacco tar. A. H. Roffo. *Bol. inst. med. exptl. estud. cancer* **16**, 1-38; *Z. Krebsforsch.* **49**, 588-97(1939); cf. *C. A.* **33**, 5906[8].—A product was obtained from a cancer-producing tobacco tar by distn. that has the spectrographic qualities and fluorescence of 1,2-benzopyrene. This product is strongly carcinogenic; it causes the formation in rabbits of malignant tumors that by their extensive invasive and destructive growth develop like carcinomas. The animals die usually in 1-2 years after the start of the expt. The first lesions appear earlier than when the whole tobacco tar is used. As a result of these expts. it seems justifiable to attribute the carcinogenic action of whole tobacco tar to the tobacco benzopyrene it contains among countless other substances. Harriet F. Holmes

The fat morphology of carcinoma with particular reference to the disjunction of the tumor cells. B. Kellner. *Z. Krebsforsch.* **49**, 633-56(1939).—A study was made of the fat content of 150 cancers and fat was found abundantly in all with the exception of 2 cases of ulcus rodens cutis. Fat is seldom deposited in uninjured cancer cells, only if from a tissue, the cells of which normally contain fat. Half of the tumors do not show areas of necrosis. Areas of necrosis when present always show a fat-contg. margin and scattered masses of fat. The greater part of the fat of the cancers is in small foci of degeneration, the localization and structure of which are quite regular and depend on the type of tumor. The cells of these small foci often show disjunction and such cells break through the connective tissue and make their way to the lymph vessels. In carcinoma without metastasis the disjoined cells are injured and break down in the stroma, and in carcinoma with metastasis the disjoined cells divide and are to be found both in the stroma and in the lymph vessels. By histochem. methods it is possible to find an increase of doubly refractive lipoids as well as neutral fats in the foci of degeneration and the areas of necrosis. The metastases show the same type and localization of foci of degeneration as the primary growth. The stroma always contains fat, mostly in the fibroblasts. The lipoids arise mostly from tumor particles that have undergone degeneration. The nuclei of the cancer cells do not contain fat. There is no relation between the fat content of the cancer and the state of nutrition of the organism. H. F. H.

The specific action of dysentery serums of the Shiga and Flexner types. E. T. Pavlova and L. S. Bazilevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 45-51 (in English, 51)(1939). Rabbit serums of the Shiga and Flexner-Hiss types of dysentery are sp., and one cannot be used as a substitute for the other in serotherapeutic practice. S. A. Karjala

The dysentery antitoxin content of the blood of healthy persons, dysentery patients and dysentery bacillus carriers. M. A. Zelikina, T. A. Gogoleva and B. L. Itskson. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 75-83(in English, 83)(1939).—The equivs. of Shiga antitoxin in the blood of healthy persons, dysentery patients during the acute period of the disease or during convalescence, and chronic Shiga dysentery patients were 0.12, 0.96-3.8 and 56 units/cc., resp. S. A. Karjala

Passive immunity in bacillary dysentery. O. O. Gartokh and M. A. Zelikina. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 62-74(in English, 74)(1939).—The amt. of antitoxin required to prevent intoxication by 2 lethal doses of dysentery toxin is 10 times as great in prophylaxis expts. as in neutralization expts. *in vitro*. The mortality values obtained when Shiga antiserum is given to mice 0.5 min., 3 and 5.5 hrs. after injection of 2 lethal doses of toxin are 0, 80 and 90%, resp. The mortality values when 20, 200 and 2000 antitoxin equivs. are given 3 hrs. after injection of 2 lethal doses are 50, 70 and 60%, resp. S. A. Karjala

The significance of the Vi antigen of the typhoid bacillus in obtaining a high immunizing effect upon vaccination. V. M. Berman and M. I. Kanevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 103-25(in English, 121-5)(1939). The completeness and duration of typhoid immunity in white mice is directly related to the content of *Vi* antigen in the typhoid strains. S. A. Karjala

The significance of the Vi antigen of the typhoid bacillus for passive immunity. The serotherapy of typhoid fever. V. M. Berman and M. I. Kanevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 126-41(in English, 141)(1939).—Intravenous or hypodermal injection of *Vi* antiserum into white mice 3 and 24 hrs. before or 1 hr. after intraperitoneal inoculation with 3 lethal doses of virulent typhoid cultures protects the animals from infection. Serums free from *Vi* antibody show little protective effect either in prophylactic or therapeutic treatment. S. A. Karjala

The phagocytizing capacity of blood in human brucellosis. B. P. Pervushin. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 17-25(in English, 25)(1939). The whole blood of patients who have recovered from brucellosis possesses a high phagocytizing capacity. This capacity increases progressively from the onset of the disease and may be used as one of the criteria in the diagnosis of brucellosis. S. A. Karjala

Changes in the nuclei of the flat stratified epithelium as a result of acute inflammation. A. K. Sofoterov. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 69-81(in English, 80-1)(1939).—Turpentine and Ammargen (ammoniacal soln. of Ag) in 1.25% soln. cause a diminution in the nuclear size of the cells of the flat stratified epithelium directly affected by the solns. and an increase in the cells adjacent to the inflammatory focus, while weak solns. of 1:10,000-1:20,000 cause an increase in the nuclei of the cells directly affected. Methylcholanthrene (1:2000-1:3000) and progynon (a cryst. follicular hormone contg. 250,000 I. U./cc.) caused a stable increase in the nuclei at the site of application. A 1% procaine soln. causes little change in nuclear size, but 0.25% solns. cause a distinct decrease. A 1.25% soln. of Ammargen causes a diminution in the nuclear size of cells in cancer tissue. S. A. Karjala

Protein metabolism in developing malignant neoplasms. I. Nitrogen balance in rabbits affected with Brown-Pearce cancer. F. A. Sverdlova. *Arch. sci. biol.* (U. S. S. R.) **54**, No. 3, 95-101(in English, 100-1)(1939). No evident changes were noted in the N balance of rabbits immediately after testicular inoculation with Brown-Pearce tumor. On the 9th-10th day after inoculation a distinct decrease in urea-N excretion occurs, which is not connected with the development of metastases in the liver and kidneys. The total N of the urine does not show any characteristic changes during tumor development. S. A. Karjala

Comparative glycogen deposit in the liver and muscles of rats after administration of different sugars in physiological and pathological conditions. I. Experiments on healthy rats. I. Z. Spector. *Bull. biol. méd. expti. U. R. S. S.* **8**, 151-3(1939)(in English).—The glycogen (I) deposit in the liver and muscles of white male rats reaches a max. 90 min. after sugar administration, maintains this level for 3 hrs. and then falls off. The av. contents of I in the livers of rats starved for 20 hrs. and then given 200 mg./100 g. body wt. of glucose, fructose, sucrose, invert sugar and galactose were 0.913, 1.605, 1.110, 1.477 and 0.730 g. %, resp. The liver and muscles of control rats (killed after starvation for 20 hrs.) contained an av. of 0.154 and 0.083 g. %, resp., of I. The muscles

of rats fed the same sugars showed 0.126, 0.170, 0.210, 0.255 and 0.194 g. % of I, resp. S. A. Karjala

Changes in the oxidation coefficient in cancer patients. L. M. Sidorov. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 164–7 (1939) (in English).—The ratio of the O required for complete oxidation of the suboxidized components of urine to the total N is called the oxidation coeff. (I). In healthy persons its normal max. is 1.65. Of 25 cancer patients 16 had a I of 1.75–2.28 (av. 1.96), 4 had the normal max. of 1.64 1.67 and 5 had a I in the normal range of 1.41 1.47. S. A. Karjala

The effect of insulin on the "antiblastic" properties of the spleen. N. S. Veller. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 239–42 (1939) (in English).—The inhibitory influence of insulin (I) on tumor growth is to be attributed to the stimulation of the "antiblastic" properties of the spleen and not to the hypoglucemia which results from the administration of I. S. A. Karjala

The urinary ratio (carbon/nitrogen) in various forms of anoxemia. S. N. Smitsyn. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 264–5 (1939) (in German); cf. *C. A.* **34**, 4958.—In all cases of extended heart and lung diseases and in many cases of polycythemia and anemia the C/N ratio of the urine is greater than 1, with the highest value obtained in 34 cases 1.46. In only 4 cases was the value below 1 (0.93 0.97), although still higher than the normal of 0.86. Destruction of the oxidative processes in these diseases, with an increase in incompletely oxidized products, results in an increase in the C of the urine, while little change in N elimination occurs. S. A. Karjala

The hemato-encephalic barrier and some physicochemical properties of the cerebrospinal fluid and the serum. V. V. Efimov and F. S. Lokshina. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 287–90 (1939) (in French).—The differences in the interfacial tension and the cond. between the cerebrospinal fluid and the blood in patients with schizophrenia, progressive paralysis, brain syphilis, epilepsy and arteriosclerosis of the brain show wide variations from the normal with no regularities and cannot be used for diagnostic purposes. These wide differences are attributed to variations in electrolyte concn. rather than concn of capillary active substances at the interface. S. A. K.

Acid-base equilibrium in blood serum in cardiac insufficiency. L. M. Georgievskaya, E. A. Kozlova and N. A. Tolubeeva. *Klin. Med.* (U. S. S. R.) **17**, No. 11, 46–62 (1939).—Cardiosclerosis without cardiac insufficiency is characterized by an increase in mineral salts in the blood. With cardiac insufficiency a decrease in CO_2 and an occasional decrease in protein are observed. In severe cases of cardiac insufficiency there is a decrease in pH, protein and CO_2, with an increase in P, K and Mg. S. A. Karjala

Acid-base equilibrium in blood serum in arteriosclerosis and essential hypertonia. L. M. Georgievskaya, E. A. Kozlova and N. A. Tolubeeva. *Klin. Med.* (U. S. S. R.) **17**, No. 11, 63–70 (1939).—Arteriosclerosis and essential hypertonia without cardiac insufficiency show no deviations from the normal in pH, CO_2, org. acids, P, K, Ca, Mg or protein. Slight increases in Na and Cl are sometimes observed. S. A. Karjala

Hippuric acid elimination in urine after loading with benzoic acid in surgical kidney ailments. Iso Suzuki. *Tôhoku J. Exptl. Med.* **37**, 346–59 (1939).—Patients were given 2.4 g. of Na benzoate (I) in 100 cc. of water. Hippuric acid (II) in the urine was detd. by Quick's method *Am. J. Med. Sci.* **185**, 630–5 (1933)). In patients with bilateral kidney tuberculosis the excretion of II after loading with I was restricted, in contrast to those with sound kidneys. The procedure could be applied in the testing of kidney function, but it has no advantages over the conventional methods. T. Laanes

The fate of dry substance, ash and total nitrogen in liver injury. Tsi-Tsao Chen. *Tôhoku J. Exptl. Med.* **37**, 360–6 (1939).—After 4 daily injections of 0.5 cc. per kg. of body wt. of 0.4% soln. of P in olive oil, or ligature of bile ducts the liver of rabbits showed an increase in weight (water), a decrease in dry substance, ash and N in relation to normal fresh liver. The amt. fluctuates according to the stage of poisoning. **Nitrogen distribution in phosphorus liver.** *Ibid.* 367–72.—In hydrolyzates of rabbit liver tissue, poisoned by P injections, the amt. of total N and amino acid N is increased in relation to dried liver, and decreased in relation to the fresh liver of control animals. T. Laanes

Variations in the carbon dioxide content of the blood in epilepsy. E. L. Gibbs, W. G. Lennox and F. A. Gibbs *Arch. Neurol. Psychiat.* **42**, 223–9 (1940).—The blood of epileptic individuals showed normal O_2, Na and K between seizures and in time relation to clinical and subclinical seizures. In patients subject to petit mal seizures CO_2 values in most cases were abnormally low, whereas in grand mal the CO_2 values were abnormally high. Spontaneous seizures were always preceded by abnormal fluctuations in the CO_2 content of arterial and internal jugular blood. There appears to be a causal linkage between the CO_2 content of the blood and seizures. G. H. W. Lucas

Adjustment of acid-base balance of patients with petit mal epilepsy to overventilation. L. F. Nims, E. L. Gibbs, W. G. Lennox, F. A. Gibbs and Denis Williams. *Arch. Neurol. Psychiat.* **42**, 262–9 (1940).—Overventilation usually produced a greater drop in the CO_2 content of internal jugular blood in patients with petit mal epilepsy than in control subjects. The low level reached also persists for a longer time than in normal subjects. The epileptic individual appears to have an acid-base loop of greater area than normal subjects. G. H. W. Lucas

Dental caries among Eskimos of the Kuskokwim area of Alaska. I. Clinical and bacteriologic findings. Theodor Rosebury and L. M. Waugh. *Am. J. Diseases Children* **57**, 871–93 (1939). **II. Biochemical characteristics of stimulated saliva correlated with dental caries and occurrence of salivary calculus.** Maxwell Karshan, Theodor Rosebury and L. M. Waugh. *Ibid.* 1026–34. The total Ca and inorg. P contents and the CO_2 capacity of saliva were higher in a group free from caries than in a group with active caries. The percentage of Ca removed by shaking a specimen of saliva with $Ca_3(PO_4)_2$ was higher and that of P lower in the group free from caries. **III. A dietary study of three Eskimo settlements.** Theodor Rosebury and Maxwell Karshan. *Ibid.* 1343–62.—The use of pilot bread or ship biscuit appeared to be responsible for dental caries in the settlements. This bread was capable of replacing coarse raw rice or corn in exptl. diets which produce fissure caries in rats (cf. *C. A.* **28**, 7314[2]). Other dietary constituents, Ca, P, fat, protein, carbohydrate, vitamin D, and cereal and grain foods appeared to have no influence on the incidence of caries. E. R. M.

The interchangeability of the elements chlorine and iodine in culture media for human thyroid fibroblasts. Johannes P. M. Vogelaar and Eleanor Erlichman. *Am. J. Cancer* **37**, 242–51 (1939). The replacement of approx. 80% of the chlorides of the culture media with an equiv. amt. of the corresponding iodides had little effect on the growth of explants of human thyroid fibroblasts. Good growth of the fibroblasts was obtained in media contg. 0.075 *M* NaI, while growth was normal or less than normal in media contg. 0.126 *M* NaI. The literature dealing with the effect of I and I compds. on growth of tissues *in vitro* is discussed. E. R. Main

Investigations on the serological specificity of experimental tumors. The serological specificity of benzopyrene tumors of rats. L. Dmochowski. *Am. J. Cancer* **37**, 252–64 (1939).—Serums from rabbits and rats which had been given intravenous injections of exts. of benzopyrene tumors, Jensen sarcomas and Walker carcinomas gave pos. complement-fixation reactions with heated saline exts. of the tumors and weaker pos. reactions with heated saline exts. of some normal rat tissues. The antigenic properties which distinguish tumor tissue from normal tissue are the same as those which characterize rapidly dying tissue. E. R. Main

Chemical carcinogenic agents. Geo. T. Caldwell. *J. Urol* **42**, 651–68 (1939).—A lecture. E. R. Main

The effect of surgical operations on the level of cevitamic acid in the blood. Charles C. Lund. *New Engl. J. Med.* **221**, 123–7 (1939).—The cevitamic acid content of the plasma is often lowered after operations, the extent of the

mous and scirrhous carcinomas and carcinoma of the rectum. The serums of healthy individuals all gave a normal reaction. Control cases with diseases without marked inflammation gave a pos. reaction of 11% and cases with inflammatory diseases a pos. reaction of 65%. The entire group of 164 controls gave a false reaction of 36.4%. The albumin content of the serum was always detd. and a relation between the polarographic values and the albumin content could not always be demonstrated, nor did the speed of sedimentation of the red blood corpuscles always agree with the polarographic findings. A new method of Waldschmidt-Leitz and K. Mayer is at present under trial and gives hope of an increase in specificity. The SH-activity of the serum toward methylglyoxalase was tried on 70 serums, but the method proved to be too involved and unreliable for a cancer reaction. H. F. H.

Carcinogenic benzopyrene obtained from tobacco tar. A. H. Roffo. *Bol. inst. med. exptl. estud. cancer* **16**, 1-38; *Z. Krebsforsch.* **49**, 588-97(1939); cf. *C. A.* **33**, 5906⁸.—A product was obtained from a cancer-producing tobacco tar by distn. that has the spectrographic qualities and fluorescence of 1,2-benzopyrene. This product is strongly carcinogenic; it causes the formation in rabbits of malignant tumors that by their extensive invasive and destructive growth develop like carcinomas. The animals die usually in 1-2 years after the start of the expt. The first lesions appear earlier than when the whole tobacco tar is used. As a result of these expts. it seems justifiable to attribute the carcinogenic action of whole tobacco tar to the tobacco benzopyrene it contains among countless other substances. Harriet F. Holmes

The fat morphology of carcinoma with particular reference to the disjunction of the tumor cells. B. Kellner. *Z. Krebsforsch.* **49**, 633-56(1939).—A study was made of the fat content of 150 cancers and fat was found abundantly in all with the exception of 2 cases of ulcus rodens cutis. Fat is seldom deposited in uninjured cancer cells, only if from a tissue, the cells of which normally contain fat. Half of the tumors do not show areas of necrosis. Areas of necrosis when present always show a fat-containing margin and scattered masses of fat. The greater part of the fat of the cancers is in small foci of degeneration, the localization and structure of which are quite regular and depend on the type of tumor. The cells of these small foci often show disjunction and such cells break through the connective tissue and make their way to the lymph vessels. In carcinoma without metastasis the disjoined cells are injured and break down in the stroma, and in carcinoma with metastasis the disjoined cells divide and are to be found both in the stroma and in the lymph vessels. By histochem. methods it is possible to find an increase of doubly refractive lipoids as well as neutral fats in the foci of degeneration and the areas of necrosis. The metastases show the same type and localization of foci of degeneration as the primary growth. The stroma always contains fat, mostly in the fibroblasts. The lipoids arise mostly from tumor particles that have undergone degeneration. The nuclei of the cancer cells do not contain fat. There is no relation between the fat content of the cancer and the state of nutrition of the organism. H. F. H.

The specific action of dysentery serums of the Shiga and Flexner types. E. T. Pavlova and L. S. Bazilevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 45-51 (in English, 51)(1939).—Rabbit serums of the Shiga and Flexner-Hiss types of dysentery are sp., and one cannot be used as a substitute for the other in serotherapeutic practice. S. A. Karjala

The dysentery antitoxin content of the blood of healthy persons, dysentery patients and dysentery bacillus carriers. M. A. Zelikina, T. A. Gogoleva and B. L. Itskson. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 75-83(in English, 83)(1939).—The equivs. of Shiga antitoxin in the blood of healthy persons, dysentery patients during the acute period of the disease or during convalescence, and chronic Shiga dysentery patients were 0.12, 0.96-3.8 and 56 units/cc., resp. S. A. Karjala

Passive immunity in bacillary dysentery. O. O. Gantokh and M. A. Zelikina. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 62-74(in English, 74)(1939).—The amt. of antitoxin required to prevent intoxication by 2 lethal doses of dysentery toxin is 10 times as great in prophylaxis expts. as in neutralization expts. *in vitro*. The mortality values obtained when Shiga antiserum is given to mice 0.5 min., 3 and 5.5 hrs. after injection of 2 lethal doses of toxin are 0, 80 and 90%, resp. The mortality values when 20, 200 and 2000 antitoxin equivs. are given 3 hrs. after injection of 2 lethal doses are 50, 70 and 60%, resp. S. A. Karjala

The significance of the Vi antigen of the typhoid bacillus in obtaining a high immunizing effect upon vaccination. V. M. Berman and M. I. Kanevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 103-25(in English, 124-5)(1939).—The completeness and duration of typhoid immunity in white mice is directly related to the content of *Vi* antigen in the typhoid strains. S. A. Karjala

The significance of the Vi antigen of the typhoid bacillus for passive immunity. The serotherapy of typhoid fever. V. M. Berman and M. I. Kanevskaya. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 1, 126-41(in English, 141)(1939). Intravenous or hypodermal injection of *Vi* antiserum into white mice 3 and 24 hrs. before or 1 hr. after intraperitoneal inoculation with 3 lethal doses of virulent typhoid cultures protects the animals from infection. Serums free from *Vi* antibody show little protective effect either in prophylactic or therapeutic treatment. S. A. Karjala

The phagocytizing capacity of blood in human brucellosis. B. P. Pervushin. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 17-25(in English, 25)(1939). The whole blood of patients who have recovered from brucellosis possesses a high phagocytizing capacity. This capacity increases progressively from the onset of the disease and may be used as one of the criteria in the diagnosis of brucellosis. S. A. Karjala

Changes in the nuclei of the flat stratified epithelium as a result of acute inflammation. A. K. Sofoterov. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 69-81(in English, 80-1)(1939). Turpentine and Ammargen (ammoniacal soln. of Ag) in 1.25% soln. cause a diminution in the nuclear size of the cells of the flat stratified epithelium directly affected by the solns. and an increase in the cells adjacent to the inflammatory focus, while weak solns. of 1:10,000-1:20,000 cause an increase in the nuclei of the cells directly affected. Methylcholanthrene (1:2000-1:3000) and progynon (a cryst. follicular hormone contg. 250,000 I. U./cc.) caused a stable increase in the nuclei at the site of application. A 1% procaine soln. causes little change in nuclear size, but 0.25% solns. cause a distinct decrease. A 1.25% soln. of Ammargen causes a diminution in the nuclear size of cells in cancer tissue. S. A. Karjala

Protein metabolism in developing malignant neoplasms. I. Nitrogen balance in rabbits affected with Brown-Pearce cancer. F. A. Sverdlova. *Arch. sci. biol.* (U. S. S. R.) **54**, No. 3, 95-101(in English, 100-1)(1939).—No evident changes were noted in the N balance of rabbits immediately after testicular inoculation with Brown-Pearce tumor. On the 9th-10th day after inoculation a distinct decrease in urea-N excretion occurs, which is not connected with the development of metastases in the liver and kidneys. The total N of the urine does not show any characteristic changes during tumor development. S. A. Karjala

Comparative glycogen deposit in the liver and muscles of rats after administration of different sugars in physiological and pathological conditions. I. Experiments on healthy rats. I. Z. Spector. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 151-3(1939)(in English). The glycogen (I) deposit in the liver and muscles of white male rats reaches a max. 90 min. after sugar administration, maintains this level for 3 hrs. and then falls off. The av. contents of I in the livers of rats starved for 20 hrs. and then given 200 mg./100 g. body wt. of glucose, fructose, sucrose, invert sugar and galactose were 0.913, 1.605, 1.110, 1.477 and 0.730 g. %, resp. The liver and muscles of control rats (killed after starvation for 20 hrs.) contained an av. of 0.154 and 0.083 g. %, resp., of I. The muscles

of rats fed the same sugars showed 0.126, 0.170, 0.210, 0.255 and 0.194 g. % of I, resp. S. A. Karjala

Changes in the oxidation coefficient in cancer patients. L. M. Sidorov. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 164-7 (1939) (in English).—The ratio of the O required for complete oxidation of the suboxidized components of urine to the total N is called the oxidation coeff. (I). In healthy persons its normal max. is 1.65. Of 25 cancer patients 16 had a I of 1.75-2.28 (av. 1.96), 4 had the normal max. of 1.64-1.67 and 5 had a I in the normal range of 1.41-1.47. S. A. Karjala

The effect of insulin on the "antiblastic" properties of the spleen. N. S. Veller. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 239-42 (1939) (in English).—The inhibitory influence of insulin (I) on tumor growth is to be attributed to the stimulation of the "antiblastic" properties of the spleen and not to the hypoglucemia which results from the administration of I. S. A. Karjala

The urinary ratio (carbon/nitrogen) in various forms of anoxemia. S. N. Smitsyn. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 264-5 (1939) (in German); cf. *C. A.* **34**, 1958.—In all cases of extended heart and lung diseases and in many cases of polycythemia and anemia the C/N ratio of the urine is greater than 1, with the highest value obtained in 34 cases 1.10. In only 4 cases was the value below 1 (0.93-0.97), although still higher than the normal of 0.86. Destruction of the oxidative processes in these diseases, with an increase in incompletely oxidized products, results in an increase in the C of the urine, while little change in N elimination occurs. S. A. Karjala

The hemato-encephalic barrier and some physicochemical properties of the cerebrospinal fluid and the serum. V. V. Efimov and E. S. Lokshina. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 287-90 (1939) (in French).—The differences in the interfacial tension and the cond. between the cerebrospinal fluid and the blood in patients with schizophrenia, progressive paralysis, brain syphilis, epilepsy and arteriosclerosis of the brain show wide variations from the normal with no regularities and cannot be used for diagnostic purposes. These wide differences are attributed to variations in electrolyte concn. rather than concn. of capillary active substances at the interface. S. A. K.

Acid-base equilibrium in blood serum in cardiac insufficiency. L. M. Georgievskaya, E. A. Kozlova and N. A. Tolubeeva. *Klin. Med.* (U. S. S. R.) **17**, No. 11, 46-62 (1939). Cardiosclerosis without cardiac insufficiency is characterized by an increase in mineral salts in the blood. With cardiac insufficiency a decrease in CO_2 and an occasional decrease in protein are observed. In severe cases of cardiac insufficiency there is a decrease in pH, protein and CO_2, with an increase in P, K and Mg. S. A. Karjala

Acid-base equilibrium in blood serum in arteriosclerosis and essential hypertonia. L. M. Georgievskaya, E. A. Kozlova and N. A. Tolubeeva. *Klin. Med.* (U. S. S. R.) **17**, No. 11, 63-70 (1939).—Arteriosclerosis and essential hypertonia without cardiac insufficiency show no deviations from the normal in pH, CO_2, org. acids, P, K, Ca, Mg or protein. Slight increases in Na and Cl are sometimes observed. S. A. Karjala

Hippuric acid elimination in urine after loading with benzoic acid in surgical kidney ailments. Iso Suzuki. *Tôhoku J. Exptl. Med.* **37**, 346-59 (1939).—Patients were given 2.4 g. of Na benzoate (I) in 100 cc. of water. Hippuric acid (II) in the urine was detd. by Quick's method *Am. J. Med. Sci.* **185**, 630-5 (1933). In patients with bilateral kidney tuberculosis the excretion of II after loading with I was restricted, in contrast to those with sound kidneys. The procedure could be applied in the testing of kidney function, but it has no advantages over the conventional methods. T. Laanes

The fate of dry substance, ash and total nitrogen in liver injury. Tsi-Tsao Chen. *Tôhoku J. Exptl. Med.* **37**, 360-6 (1939).—After 4 daily injections of 0.5 cc. per kg. of body wt. of 0.4% soln. of P in olive oil, or ligature of bile ducts the liver of rabbits showed an increase in weight (water), a decrease in dry substance, ash and N in relation to normal fresh liver. The amt. fluctuates according to the stage of poisoning. **Nitrogen distribution in phosphorus liver.** *Ibid.* 367-72.—In hydrolyzates of rabbit liver tissue, poisoned by P injections, the amt. of total N and amino acid N is increased in relation to dried liver, and decreased in relation to the fresh liver of control animals. T. Laanes

Variations in the carbon dioxide content of the blood in epilepsy. E. L. Gibbs, W. G. Lennox and F. A. Gibbs. *Arch. Neurol. Psychiat.* **42**, 223-9 (1940).—The blood of epileptic individuals showed normal O_2, Na and K between seizures and in time relation to clinical and subclinical seizures. In patients subject to petit mal seizures CO_2 values in most cases were abnormally low, whereas in grand mal the CO_2 values were abnormally high. Spontaneous seizures were always preceded by abnormal fluctuations in the CO_2 content of arterial and internal jugular blood. There appears to be a causal linkage between the CO_2 content of the blood and seizures. G. H. W. Lucas

Adjustment of acid-base balance of patients with petit mal epilepsy to overventilation. L. F. Nims, E. L. Gibbs, W. G. Lennox, F. A. Gibbs and Denis Williams. *Arch. Neurol. Psychiat.* **42**, 262-9 (1940).—Overventilation usually produced a greater drop in the CO_2 content of internal jugular blood in patients with petit mal epilepsy than in control subjects. The low level reached also persists for a longer time than in normal subjects. The epileptic individual appears to have an acid-base loop of greater area than normal subjects. G. H. W. Lucas

Dental caries among Eskimos of the Kuskokwim area of Alaska. I. Clinical and bacteriologic findings. Theodor Rosebury and L. M. Waugh. *Am. J. Diseases Children* **57**, 871-93 (1939). II. **Biochemical characteristics of stimulated saliva correlated with dental caries and occurrence of salivary calculus.** Maxwell Karshan, Theodor Rosebury and L. M. Waugh. *Ibid.* 1026-34.—The total Ca and inorg. P contents and the CO_2 capacity of saliva were higher in a group free from caries than in a group with active caries. The percentage of Ca removed by shaking a specimen of saliva with $Ca_3(PO_4)_2$ was higher and that of P lower in the group free from caries. III. **A dietary study of three Eskimo settlements.** Theodor Rosebury and Maxwell Karshan. *Ibid.* 1343-62.—The use of pilot bread or ship biscuit appeared to be responsible for dental caries in the settlements. This bread was capable of replacing coarse raw rice or corn in exptl. diets which produce fissure caries in rats (cf. *C. A.* **28**, 7314²). Other dietary constituents, Ca, P, fat, protein, carbohydrate, vitamin D, and cereal and grain foods appeared to have no influence on the incidence of caries. E. R. M.

The interchangeability of the elements chlorine and iodine in culture media for human thyroid fibroblasts. Johannes P. M. Vogelaar and Eleanor Erlichman. *Am. J. Cancer* **37**, 242-51 (1939).—The replacement of approx. 80% of the chlorides of the culture media with an equiv. amt. of the corresponding iodides had little effect on the growth of explants of human thyroid fibroblasts. Good growth of the fibroblasts was obtained in media contg. 0.075 *M* NaI, while growth was normal or less than normal in media contg. 0.126 *M* NaI. The literature dealing with the effect of I and I compds. on growth of tissues *in vitro* is discussed. E. R. Main

Investigations on the serological specificity of experimental tumors. The serological specificity of benzopyrene tumors of rats. L. Dmochowski. *Am. J. Cancer* **37**, 252-64 (1939).—Serums from rabbits and rats which had been given intravenous injections of exts. of benzopyrene tumors, Jensen sarcomas and Walker carcinomas gave pos. complement-fixation reactions with heated saline exts. of the tumors and weaker pos. reactions with heated saline exts. of some normal rat tissues. The antigenic properties which distinguish tumor tissue from normal tissue are the same as those which characterize rapidly dying tissue. E. R. Main

Chemical carcinogenic agents. Geo. T. Caldwell. *J. Urol.* **42**, 651-68 (1939).—A lecture. E. R. Main

The effect of surgical operations on the level of cevitamic acid in the blood. Charles C. Lund. *New Engl. J. Med.* **221**, 123-7 (1939).—The cevitamic acid content of the plasma is often lowered after operations, the extent of the

reduction depending on the initial content. Reductions of 30–50% may be found when the preoperative level is 0.8 mg. % or more. E. R. Main

The chemical and clinical diagnosis of acute alcoholism. Walter W. Jetter. *New Engl. J. Med.* **221**, 1019-24 (1939); cf. *C. A.* **33**, 8763[8].—A discussion of the correlation of chem. data with acute alc. intoxication and of the advantages of the use of chem. methods. E. R. Main

Some observations on the plasmalipides in acute schizophrenia. Erkki Jokivartio and Tauro Kalaja. *Acta Psychiat. Neurol.* **13**, 667–75(1939).—The plasma total cholesterol and ether-sol. phosphatide P of 40 acute, relatively young male and female schizophrenic patients are compared with those of normal persons on the same diet. Residue of an ether ext. from a Bloor EtOH-ether residue is ashed with H_2SO_4 and HNO_3, neutralized and detd. by the Fiske-Subbarow method (*C. A.* **20**, 1092). An aliquot of Bloor ext., evapd. and taken up in chloroform, is used for Liebermann-Burchardt's reaction. The cholesterol of schizophrenic patients varies more than that of normal subjects, though the means are identical. Insulin and cardiazole treatment are followed by both fall and rise. Mean phosphatide P is lower in schizophrenic patients, and does not rise after cardiazole or insulin administration, even though the patients recover. J. McAfee

Ether-soluble plasma phosphatides in schizophrenia. Erkki Jokivartio. *Acta Psychiat. Neurol.*, Suppl. **21**, 98 pp. (1939) (in English).—P values of ether-sol. phosphatides of plasma are detd. photocolorimetrically by a modified Bloor method, with an error of ±2%. Patients are selected for similarity in age, phys. health, diet and typical psychic symptoms. Twenty-eight are women, 32 men. Ten nurses and 10 male attendants of the same age range and on the same diet are used as controls. No menstruating or pregnant women are included. Samples are taken after fasting 12 hrs., after a breakfast of gruel and unbuttered bread, at noon and the following morning. Fasting values do not differ from the others. Normal values vary from 8.72 to 12.87 mg. %, mean 10.22, women being slightly higher than men. Body build does not correlate with values. Of 40 acute cases (153 samples) 97.5% are below the normal av., 92.5% below the lower limit for normal. The av. equals 5.79 mg. %, range 2.72–12.87, women being higher. No definite connection is found between P values and duration of illness. Chronic cases showing change in state ("process") in 18 tests on 6 patients vary from 4.92 to 7.02 mg. %, av. 5.76. Changes at the end of a year are slight, with no relation to psychic state. Unchanging (defect-state) cases in 40 tests on 14 patients range from 6.86 to 9.69, av. 8.30. Women tend to show lower values. Psychotic daily curves may fluctuate more than normal. Though consistent relation between P values and changes in psychic condition as a result of insulin or cardiazole treatment is not apparent, prognosis for patients with lower values is better. No increase is seen in patients unimproved by shock treatment. J. McAfee

Endogenous carbon monoxide in the blood. M. Loeper and E. Gilbrin. *Presse méd.* **47**, 1649–50(1939); cf. *C. A.* **34**, 1493.—A relatively high CO content of the blood was observed in various types of anemia, gastric cancer, some polycythemias, alc. cirrhosis, intoxications and some metabolic diseases such as diabetes and oxalemia. The theory is presented that CO is a product of sugar metabolism. A. E. Meyer

Chemistry of the brain under the conditions of worm intoxication of animals. V. D. Semenov. *Bull. biol. méd. exptl. U. R. S. S.* **4**, 169–71(1937); *Chem. Zentr.* **1938, II**, 3420.—After subcutaneous injection of the body fluids of *Ascaris suum* the chem. compn. of the brain, especially its P metabolism, underwent essential changes. M. G. Moore

The action of worm poisons on the chemical composition of animal blood. Residual nitrogen in the blood of cats. V. D. Semenov. *Bull. biol. méd. exptl. U. R. S. S.* **4**, 172–5(1937); *Chem. Zentr.* **1938, II**, 3420.—The residual N content of the blood of cats decreased under the influence of alc. exts. of *Ascaris suum*, *Toxocara mystax*, *Dipilidium caninum* and *Hydatigera taeniaeformis*. M. G. Moore

Renal changes in alkalosis. B. M. Nicol. *Quart. J. Med.* **9**, 91–105(1940).—Renal damage was indicated by the presence of albumin and casts in the urine if dehydration was present. All of such cases showed alkalemia, hypochloremia and azotemia. Some were dehydrated, others not. Damaged renal tubules fail to secrete alk. radicals and hence aggravate an alkalemia. 29 references. John T. Myers

The serum cholinesterase in jaundice and diseases of the liver. Brian McArdle. *Quart. J. Med.* **9**, 107–27 (1940).—In 40 normal adults the cholinesterase ranged from 51 to 121 units with a mean of 78. For children (7–15 yrs.) the range was 71–166 with a mean of 105. In diseases of the liver the values were much lower, 76% of the cases studied being below 50. The range was 10–70 with a mean of 36 units. In 82 patients with miscellaneous diseases the values were between 13 and 138 with a mean of 71; of these cases 20 had values below 50, in many of which there was evidence of liver damage. In 21 cases of obstructive jaundice the value was 50 or above in 87% of the cases. In jaundice of hepatic origin it was below 50 in 87% of the cases. 45 references. J. T. Myers

Weltmann's serum-coagulation test. Simplified technique. Robert Teufl. *J. Med.* **21**, 27–30(1940).—The test is based on heat coagulation of serum in the presence of crystd. $CaCl_2$. J. Pinchack

Vi antigen of B. typhosum. I. Complement fixation test with Vi antigen and its resistance to heat and chemicals. Hiroshi Ogonuki. *Kitasato Arch. Exptl. Med.* **15**, 1–6(1938).—Vi antigen is not destroyed by heat (60 or 100° for 1 hr.) or phenol (0.5%), but only dissociated. This explains the discrepancy between the loss of Vi agglutinability of Vi bacilli and their effectiveness in active immunization of mice. However, some degree of modification in the nature of Vi antigen by heat or phenol is probable. J. Pinchack

A filtrable virus isolated from rabbit. S. Kasahara, K. Doi, M. Ueda, Y. Okamoto, R. Hamano, R. Yamada and S. Tubaki. *Kitasato Arch. Expt. Med.* **15**, 31–9(1938). Five strains of a filtrable virus ("rabbit virus") immunologically similar to variola vaccinia virus were isolated during virus passages through rabbit testicles. J. P

Complement-fixation reaction in Weil's disease. Mainly on the improvement of the antigen. Gakuzi Numata. *Kitasato Arch. Expt. Med.* **15**, 45–66(1938). The antigen for the suggested complement-fixation reaction is prepd. by centrifugal pptn. of *Spirocheta uterohemorrhagica* and addn. of 0.2–0.3 cc. (optimum amt.) of a 2% alc. ext. of guaiacum resin per 10 cc. of antigen. The guaiacum resin ext. markedly enhances antigenicity. The protein-free antigen, which is more simply prepd. from autolyzed spirochetes, is antigenically equal to the pptd. spirochetal antigen, and is likewise potentiated by guaiacum resin ext. It remains unchanged for at least 3 months. J. Pinchack

The role of histamine in hypersensitiveness to human placental extract and tryptic digest placental broth. Sigetugu Nisiyama. *Kitasato Arch. Exptl. Med.* **15**, 67–79(1938).—The human placenta contains approx. 1 mg. % histamine, to the crude fraction of which hypersensitive individuals are just as reactive as to the C. P. compd. Test materials added to the histamine fraction reduce or inhibit the local reaction in the decreasing order: arginine > histidine > cysteine > adrenaline; CH_2O is inactive. Tryptic digestion does not destroy placental histamine. Acetone, tannic acid, Pb subacetate, Pb acetate, $HgCl_2$, $(NH_4)_2SO_4$, phosphomolybdic acid and phosphotungstic acid ppt. it, but not alum, iron alum, uranyl acetate, CCl_3CO_2H, HPO_3 or AmOH. Histamine or histaminoid substances are best removed from placental broth by dialysis or alc. pptn.; alc. is preferable to acetone. J. Pinchack

The optimum pH and the action of some enzymes on epidemic encephalitis virus. Norimasa Hirano and Tiyo Koyama. *Kitasato Arch. Exptl. Med.* **16**, 306–13 (1939).—Encephalitis virus was unaffected by 5 hrs.' incubation at 37° with diastase (I), trypsin (II) or lipase

(III). The incubated mixt. of virus and I, even when dild. 50 times, was destroyed after 12–18 hrs. on ice. Virus + II was similarly destroyed, even when dild. 50-100 times, but virus + III was only partially inactivated when dild. 800 times and unaffected when dild. 400 times. J. Pinchack

An evaluation of the spirochete complement-fixation reaction in comparison with the Eagle flocculation and Wassermann procedures. Paul T. Erickson and Harry Eagle. *Venereal Disease Information* 21, 31-7(1940); cf. Gachtgens, *C. A.* 24, 5847.—Phenolized suspensions of the Reiter strain of cultured spirochetes (palligen) react with syphilitic serum to give pos. complement fixation. The results compare favorably in both sensitivity and specificity with standard Wassermann and flocculation procedures. J. Pinchack

Porphyrins and diseases of the blood. Cecil James Watson. *Symposium on the Blood and Blood-Forming Organs*, Univ. Wisconsin 1939, 14-30.—A review. Fifty-four references. Maurice M. Rath

Aplastic anemia. C. P. Rhoads. *Symposium on the Blood and Blood-Forming Organs*, Univ. Wisconsin 1939, 31-40. In 15 of 30 cases studied for bile metabolism, there was a distinct rise in the total amt. of pigment excreted, the daily amt. varying from 172 to 570 mg., the av. being 308 mg. There was no evidence that the increase in pigment excretion was due to any cause other than hemolysis. Pigment metabolism indicated toxic origin of the disorder. In 6 cases definite exacerbations followed exposure to sunlight. This may be due to the presence of type III porphyrin. Patients who had been exposed to benzene poisoning presented no clin. or pathol. difference from those in which the origin was unknown. In 3 patients given amidopyrine to test the power to conjugate that substance serious exacerbations followed. The Na benzoate conversion test of Quick (cf. *C. A.* 30, 3393[8]), the bilirubin retention test and the rate of urobilinogen excretion in the urine were used to study liver function. Only 4 cases showed evidence of hepatic dysfunction on all 3 tests and in 14 of 26 other patients, one or another of tests gave abnormal results. The value of these tests is considered doubtful. Marrow studies led to the supposition that the various types of refractory anemia of unknown etiology were manifestations of poisoning due either to an increased susceptibility to the effects of the exceedingly small amts. of benzene-like compds. to which nearly all individuals are exposed unknowingly in the course of their daily occupation, or to the effect of some improper formation or metabolism of compds. similar in chem. structure but formed endogenously, such as the sex hormones or the products of breakdown of the cyclic amino acids. Maurice M. Rath

Colloid-osmotic pressure of the plasma and composition of the blood after acute hemorrhage and after hemorrhage followed by intravenous injection of a 0.9% sodium chloride solution. A. W. J. H. Hoitink. *Arch. neerland. physiol.* 24, 169-93(1939)(in English).—The colloid-osmotic pressure (c. o. p.) changes and specific c. o. p. changes on dilu. of gum acacia-NaCl solns. and blood plasma *in vitro* were examd. On dilu. of plasma *in vitro* the specific c. o. p. (the c. o. p. per unit of protein per 100 cc. of plasma) generally becomes smaller. Changes in amt. of some blood constituents were detd. after acute hemorrhage and after acute hemorrhage followed by an intravenous injection of a 0.9% NaCl soln. The plasma proteins are restored more quickly than the hemoglobin, especially after hemorrhage and subsequent injection of a NaCl soln. The nonprotein N in the plasma shows in both cases a relative or an abs. increase. After a hemorrhage and subsequent injection of a 0.9% NaCl soln., the hemoglobin and plasma proteins show for some time a greater decrease than after hemorrhage without subsequent injection. After hemorrhage, with or without subsequent intravenous injection of a NaCl soln., there is a relative increase in c. o. p. of the plasma. The specific c. o. p. remains the same or sometimes increases in spite of a simultaneous decrease of plasma proteins. This relative increase is not due to changes in concn. of salt, lactic acid or nonprotein N of the plasma, nor to pH changes or changes in the albumin/globulin ratio. **Colloid-osmotic pressure of the plasma and composition of the blood after intravenous injection of gum-salt-solution in hemorrhage.** *Ibid.* 194-205.—The c. o. p. of a gum-salt-soln. the day after sterilization by heat is greater than the c. o. p. of a nonsterilized soln. Later the c. o. p. of the sterilized soln. decreases to the value of the nonsterilized soln. The value then remains const. *In vitro* the c. o. p. of a mixt. of equal parts of serum and gum-salt-soln. equals one-half the c. o. p. of the undild. serum plus one-half the c. o. p. of the undild. gum-salt-soln. After intravenous injection of a gum-salt-soln. the c. o. p. of the plasma is greater than would be expected from a mixt. of serum and gum-salt-soln. *in vitro*. The specific c. o. p. is considerably increased after the intravenous injection of a gum-salt-soln. The intravenous injection of a gum-salt-soln. has an unfavorable influence on the restoration of plasma proteins. **Colloid-osmotic pressure and lipoids of blood plasma in connection with the spleen after acute hemorrhage and after injection of saline in hemorrhage.** *Ibid.* 206-15.—Plasma lipoids have no significance for the magnitude of the specific c. o. p. and c. o. p. of the blood plasma. The spleen plays an important part in the development of the relative increase in c. o. p. after a hemorrhage with or without subsequent intravenous injection of saline soln. Felix Saunders

Carcinomas produced in the lung of the rat subjected to the gases of combustion of petroleum. A. H. Roffo. *Bol. inst. med. exptl. estud. cancer* 16, 77-87(1939).—Preliminary note. Felix Saunders

Masculinizing and nonmasculinizing carcinomata of the cortex of the adrenal glands. Thomas H. McGavack. *Endocrinology* 26, 396-408(1940).—A report of 6 cases. Estns. of estrin, gonadotropic factor of the pituitary and androgens in the urine of 18 patients is recorded. High estrin values were obtained only in carcinoma of the adrenal, and increased bitterling responses in hyperplasia of the adrenal cortex. Felix Saunders

Estrogen metabolism in cancerous and noncancerous women. Gregory Pincus and Mark Graubard. *Endocrinology* 26, 427-32(1940).—Urinary estrogen was detd. before and after the administration of estrone and estrone plus progesterone in 5 noncancerous women and in 7 women with cancer of the cervix or fundus. Two noncancerous women with normal functional ovaries and uterus convert injected estrone in part into estriol and this conversion is enhanced by progesterone injection. Two noncancerous women with nonfunctional uteri and a hysterectomized woman did not effect this conversion but did excrete more estrogen after estrone plus progesterone than after estrone alone. The cancerous women cannot effect the conversion of estrone to estriol even with progesterone injection and in spite of the fact that their total estrogen output before injection is higher than the control group. A possible estrogenic urinary pigment is described. Felix Saunders

Urinary gonadotropic extracts and anaphylaxis in vitro. M. Van den Ende. *J. Endocrinol.* 1, 356-65(1939).—Expts. in which antibodies were demonstrated by anaphylactic sensitization confirm those of precipitin tests on antigonadotropic serum. The isolated uteri of sensitized guinea pigs react specifically to contact with urinary exts. irrespective of their hormone content. Sensitivity to human serum is also induced but anaphylactic reaction to urinary ext. is present even after specific desensitization to serum. By active sensitization to urinary exts. a higher degree of sensitivity to species (serum) antigen is induced than by passive sensitization, probably because of the occurrence of traces of serum proteins in the urinary exts. The demonstrable antibodies evoked by urinary gonadotropin are not hormone-specific. Felix Saunders

Colloid structure of gallstones. L. Aschoff. *Kolloid-Z.* 89, 107-9(1939).—The Liesegang theory can be used to explain the formation of gallstones, urinary calculi and other concretions. Felix Saunders

Etiology of tumor formation and the nature of malignancy. B. Fischer-Wasels. *Kolloid-Z.* 89, 302-6(1939).

—Tumor formation and malignancy are chem. problems. Felix Saunders

Immunity to experimental pneumococcal infection with an artificial antigen containing a saccharide of synthetic origin. Walther F. Goebel. *Science* **91**, 20–1; *J. Bact.* **39**, 33(1940).—Passive immunity to types III and VIII pneumococcal infection can be conferred on mice by the serums of rabbits immunized with an artificial antigen contg. azobenzyl glycoside of cellobiuronic acid. It is possible to confer passive immunity to type II pneumococcal infection on mice with the serums of rabbits injected with artificial antigens contg. the corresponding gentiobiuronic acid. These effects are not produced by the disaccharides cellobiose and gentiobiose. The immunity appears to be attributable to an antibody directed toward glucuronic acid. If the mol configuration of but 1 of the C atoms of the hexuronic acid constituent of the antigen is altered, its capacity to evoke immunity to type II pneumococcal infection is lost. Felix Saunders

Particulate components of normal and tumor cells. Albert Claude. *Science* **91**, 77–8(1940). Particles with a diam. of 50–150 mμ were sepd. from embryonic and tumor tissues in the high-speed centrifuge. No differences were found in the solv. of materials from different sources. The purified substance forms opalescent solns. at pH 7. In slightly acid solns. a point of min. solv. is found near pH 3.5, whereas the normal opalescence of the soln. is appreciably decreased in solns. more alk. than pH 11. The material is not pptd. from neutral solns. by heating nor by 80% alc. There is an absorption max. at λ 2600. The substance has the general compn. of a phospholipide-ribonucleoprotein complex. It may represent isolated mitochondria or fragments of mitochondria. F. S.

Histamine release from blood cells in anaphylaxis in vitro. Gerhard Katz. *Science* **91**, 221(1940). Rabbits were sensitized by several intravenous injections of egg albumin. From 10 to 30 days after the last injection, blood was taken by heart puncture, heparinized and divided into 2 samples. To 1 sample egg albumin (in Locke soln.) was added so as to make it 1:1000 egg albumin in blood. The other sample served as an untreated control. Both samples were incubated at 37° for 10 min. The plasmas were sepd. by rapid centrifugation, filtered and their histamine was extd. (cf. Code, *C. A.* **31**, 4359[6]). The assay was carried out on isolated atropinized guinea-pig ileum. In all instances in which "sensitized" blood had thus undergone "shock" *in vitro*, its plasma contained more histamine than the control samples. The differences ranged from 100 to 600% in rabbits and were also very distinct but somewhat smaller in a few expts. on sensitized dogs and guinea pigs. No differences in plasma histamine were found when blood from unsensitized animals was incubated with egg albumin and compared with untreated samples, or when cell-free plasmas from sensitized animals were incubated with antigen and compared with controls. Conclusion: Blood cells from sensitized animals release histamine into the plasma when they are in contact with the antigen. Felix Saunders

Alcoholemia and glucemia in fatigue. Vittorio Mauro. *Rass. med. ind.* **10**, 712–24(1939).—The variation of the blood EtOH (I) of normal and diabetic persons was studied at rest and after exercising with an ergostat. Samples of blood were taken at intervals from the elbow vein, and analyzed for I by the method of Widmark modified by Baglioni, Bracalon and Galanini (cf. *C. A.* **21**, 2031). In normal persons the blood I increases and then falls back to its normal value of about 0.04%. In diabetic patients the curves are irregular, sometimes increasing as a result of exercise, and sometimes falling and then increasing in repose after the exercise. M. Schubert

3,4-Benzopyrene, paramecium and the production of tumors. J. C. Mottram. *Nature* **145**, 184–5(1940).—Long exposure of paramecium to the tumor-producing hydrocarbon 3,4-benzopyrene results in the production of a few abnormal individuals. If these are cultured in normal medium, populations of cells result, presenting wide morphological variation from normal through varying degrees of abnormality to multicellular monsters. These resemble the assemblage of cells forming a cancerous tumor. E. D. Walter

Influence of nitrogen retention upon the regeneration of plasma proteins. Russell L. Holman and J. Gilmer Mebane. *J. Exptl. Med.* **71**, 299–304(1940).—Because of the clinical observation that the capacity to form new plasma proteins is sometimes impaired in cases of nephritis, expts. were carried out to det. whether the impaired function in the nephritic person is related to N retention; the expts. consisted in producing renal injury by injecting $UO_2(NO_3)_2.6H_2O$ into standard hypoproteinemic dogs and comparing the rate of formation of blood-plasma protein under these conditions of N retention with that in the uninjured dog. Despite elevations in blood nonprotein N to more than 10 times normal, no interference with plasma protein formation was observed. These elevations in nonprotein N affected principally the urea and undetd. fractions. Neither elevation in nonprotein N nor proteinuria *per se* appears to have any effect on plasma protein production. Possibly the deficient production of plasma proteins in the nephritic person is related to a more general disturbance in metabolism in which the elevation in nonprotein N is secondary. C. J. West

Distinctive substance associated with the Brown-Pearce rabbit carcinoma. I. Presence and specificity of the substance as determined by serum reactions. John G. Kidd. *J. Exptl. Med.* **71**, 335–50(1940).—A substance is regularly present in saline exts. of the Brown-Pearce rabbit carcinoma growth that is capable of fixing complement specifically in mixts. with the serums of certain rabbits which bear the tumor or in which it has recently retrogressed. **II. Properties of the substance: Discussion.** *Ibid.* 351–71.—The serologically active substance of the Brown-Pearce tumor, a complement-fixing antigen, differs notably from certain other tissue antigens in the fact that it is not effective after EtOH extn. of the tissue contg. it. Like many of the proteins and viruses it is inactivated on heating to 65° for 30 min.; and like them as well, its activity is lost on treatment with acid (to pH 4.5 or lower) or alkali (to pH 11.5 or higher). Filtration and centrifugation expts. disclosed the fact that the antigen of the tumor passed readily through collodion membranes with av. pore diams. of 383 mμ and more but was retained completely by those with av. pore diams. of 348 mμ and less. It was thrown down completely or almost completely on centrifugation at 20,000 r. p. m. for 1 hr. The findings indicate that the tumor antigen has a large and nearly uniform particle size and wt. as large as that of many of the viruses. They differentiate it sharply from the generality of "sol. antigens." C. J. West

Some constituents of elementary bodies of vaccinia. Joseph E. Smadel, George I. Lavin and Rene J. Dubos. *J. Exptl. Med.* **71**, 373–89(1940).—Nucleoprotein and S antigen were recovered in soln. after extn. of prepns. of dry elementary bodies of vaccinia with dil. NaOH; the ext. amounted to about half of the dry wt. of the virus. Elementary bodies contained about 0.4% inorg. P, practically all of which occurred in the form of a nucleoprotein contg. thymus nucleic acid. It is thought that S antigen, as ordinarily encountered, is a protein which is not in combination with nucleic acid. Qual. reactions suggesting the presence of small amts. of glucosamine were obtained in all cases. C. J. West

Scudder, John: Shock: Blood Studies as a Guide to Therapy. Philadelphia: J. B. Lippincott. 315 pp. $5.50.

H—PHARMACOLOGY

CARL F. SCHMIDT

Ammonium bicarbonate secreted by surgical maggots stimulates healing in purulent wounds. Wm. Robinson. *Am. J. Surg.* **47**, 111–15(1940).—NH_4HCO_3 is present in comparatively large amts. in the secretions of the maggot of the blowfly, *Phormia regina*. Clinical tests have shown that NH_4HCO_3, applied to purulent wounds as a 1 or 2% sterile soln. or gauze packs, has marked healing properties similar to those of the 2 other maggot secretion

products, allantoin and urea. The occurrence of NH_4-HCO_3 in maggot secretions is assocd. with the presence of the enzyme urease in maggot tissues. C. R. A. 1

Histochemical study of gold diffusion in the skeleton. Natale Di Malfetta. *Arch. ist. biochim. ital.* **11**, 285–94(1939).—Gold thioglucose (20%) suspended in oil and contg. 50% Au was injected into rabbits. On necropsy gold was found in the skeleton. E. S. G. Barron

Toxicity of mercury vapors. Mario Adamo. *Rass. med. ind.* **10**, 684–90(1939). With guinea pigs subjected to inhalations of mercury vapor under a variety of conditions, the greatest toxic action was found when the degree of humidity and the CO_2 content of the air were high. Mercury mines must be kept thoroughly oxygenated and with low humidity. E. S. G. Barron 2

Thallium intoxication. José F. Marquez, Ismael Lami and Luis Krauss. *Rev. med. cienc. afines* (Buenos Aires) **1**, No. 8, 8–15(1939). Description of 3 cases of thallium intoxication. They were treated by intravenous injections of NaI (10 to 20% solns., 0.30 to 1 g. per day). E. S. G. Barron 3

Clinical experience in the treatment of Addison's disease with desoxycorticosterone acetate. G. A. K. von dem Borne and F. Lopes Cardozo. *Nederland. Tijdschr. Geneeskunde* **84**, 231–43(1940).— Desoxycorticosterone acetate, synthesized by T. Reichstein (*C. A.* **32**, 5778) and found to be very active in animal expts., was found to be a very potent drug in Addison's disease. On a diet low in K and 10 g. of NaCl, 2.5 mg. of the sterone a day was sufficient to maintain a clinically normal blood pressure and mineral balance. This dose had a stronger action than 10 cc. of "cortin." With 10 mg. of the sterone a day, it was possible to keep the patient in balance even with a low NaCl and a high KCl intake, but this was not possible on a diet high in NaCl and low in KCl. Retention of K on a diet high in K, was prevented by this sterone in spite of a low NaCl intake. Undesirable side effects of the sterone, such as high fever, or hypoglycemia, can be prevented. In view of the potent action overdosage is not without danger, particularly with a high salt intake. R. Beutner 4

Treatment of the disease of Heine-Medin by means of potassium chlorate. H. J. Kolk. *Nederland. Tijdschr. Geneeskunde* **84**, 3888–94(1940). Doses up to 6 g. of $KClO_3$ are given, in general 100 mg., per kg. of body wt. divided into 12 doses. K reports there was no case of poisoning in the 52 cases treated and reports a marked improvement in all the cases of acute anterior poliomyelitis treated. $KClO_3$ is supposed to act by oxidation. Methemoglobin is usually found in the urine. R. Beutner 5

Effects of continued feeding of diphenylene oxide. John O. Thomas, Robert H. Wilson and C. W. Eddy. *Food Research* **5**, 23–30(1940). Albino rats fed a balanced diet contg. from 0.025 to 0.4% diphenylene oxide for 200 days showed normal wt. gains and blood picture. Urine output was increased somewhat and tissue damage was evident in the kidney but not in the liver, spleen, heart or adrenals. The use of diphenylene oxide in spray materials is thought to be free from public health danger. C. R. Fellers 6

Toxic action of glycerol in healthy and tuberculous guinea pigs. J. S. Solomidès. *Compt. rend. soc. biol.* **132**, 359–61(1939); cf. *C. A.* **33**, 8209[9].—When injected intravenously or intraperitoneally the lethal dose of undild. glycerol is 2.5 g./kg. for guinea pigs and 1 g./kg. for rabbits. Preliminary dilu. with physiol. NaCl soln. greatly decreases the toxicity. The alleged activation of the tubercle bacillus *in vivo* by glycerol may be the result of lowering the resistance of the tuberculous guinea pig. L. E. Gilson 7

Pharmacological properties of certain saturated fluorocarbons. H. C. Struck and F. B. Plattner. *J. Pharmacol.* **68**, 217–19(1940).—Breathing air contg. high concns. of decafluorobutane, C_4F_{10}, b. −4.5° and decafluorocyclopentane, C_5F_{10}, b. 23°, profoundly depressed mice but did not produce true anesthesia, the mice responding to stimuli at all times. Death followed from congestion of the lungs due to irritation. L. E. Gilson 8

Pharmacology of certain furfuryl and tetrahydrofurfuryl ammonium iodides. Edwin J. Fellows and A. E. Livingston. *J. Pharmacol.* **68**, 231–46(1940).— In animals furfuryltrimethyl-, furfuryldimethylethyl-, tetrahydrofurfuryltrimethyl- and tetrahydrofurfuryldimethylethylammonium iodides were stable in the blood and produced a marked fall in blood pressure, cardiac inhibition and depression, an increased flow of saliva, an increased tone of intestine and bladder and sometimes catharsis. These effects were prevented by atropine. The effective doses of the 4 compds. varied greatly with the mode of administration and with the species of animal used. Satn. of the furan ring decreased the parasympathetic potency but not the toxicity. Furfuryldimethylisopropyl-, furfuryldimethylpropyl-, furfuryldimethylbutyl- and furfuryldimethylamylammonium iodides had a complex and variable vascular action. L. E. Gilson 9

Influence of adrenaline on shivering and on metabolism in the cold. V. E. Hall and P. B. Goldstone. *J. Pharmacol.* **68**, 247–51(1940).— In chilled pentobarbitalized cats, adrenaline, in doses just in excess of the physiol. rate of secretion, suppresses shivering and consequently reduces the total metabolism by decreasing the amt. of O consumed by this activity. The adrenaline depresses the central motor mechanism involved in shivering. L. E. Gilson 10

Administration of drugs in food for chemotherapy studies in mouse pneumococcus infections. Raymond N. Bieter, W. P. Larson, Elizabeth M. Cranston and Milton Levine. *J. Pharmacol.* **68**, 252–8(1940); cf. *C. A.* **33**, 8300[6].—The administration of sulfanilamide and related compds. by mixing them with the food is discussed. L. E. G. 11

Experimental studies in chemotherapy of pneumococcic infections, including hydroxyethylapocupreine, sulfapyridine and certain other related compounds. M. M. Bracken, John M. Johnston, George E. Crum, David R. Patrick, H. H. Permar and W. W. G. Maclachlan. *J. Pharmacol.* **68**, 259–66(1940); cf. *C. A.* **32**, 1785[2].—All of 61 quinine and quinoline derivs. related to hydroxyethylapocupreine (I) were inferior to I in the treatment of pneumococcic infections in mice. *In vitro*, I is bacteriostatic for pneumococcus in much greater dilu. than are sulfapyridine (II) and sulfanilamide. Equal doses of I and II had the same protective power in mice infected with virulent pneumococci. The effectiveness of either I or II was increased by use of homologous antipneumococcic serum, and I and II given together enhanced the effectiveness of each other. L. E. Gilson 12

Effects of digitoxin and potassium on striated muscle. S. A. Guttman and McKeen Cattell. *J. Pharmacol.* **68**, 267–77(1940); cf. *C. A.* **32**, 4658[8].—In *Rana pipiens* sartorius muscles maintained in O_2 or air after treatment with ouabain or digitoxin there is first an increase in twitch tension and then a loss in excitability. Recovery occurs within a few min. after returning to the glucoside soln. or to unmodified Ringer soln. These effects are indistinguishable from those following treatment with Ringer soln. contg. an excess of KCl, except that in the latter case recovery occurs only in Ringer soln. contg. the normal amt. of K. Ouabain and digitoxin are equally effective and in 1:1,000,000 concn. their effects are like that of Ringer soln. contg. 5 times the usual amt. of KCl. The fall in efficiency after treatment with the digitalis glucosides is not due to increased extracellular K. L. E. Gilson 13

The metabolic fate of *N*-substituted derivatives of barbital. Milton T. Bush and Thomas C. Butler. *J. Pharmacol.* **68**, 278–83(1940); cf. *C. A.* **33**, 2986[8].—A method and app. for extg. barbital from urine are described. By isolation of the barbital from the urine of dogs it was shown that *N*-dealkylation of the Et and Me derivs. is extensive, but that of the Pr, iso-Pr, allyl, Bu and Ph *N*-substituted derivs. is slight. The effects on mice of the above compds. and 2 new compds., the iso-Bu and sec-Bu derivs., are described. L. E. Gilson 14

Protecting action of procaine against ventricular fibrillation induced by adrenaline during cyclopropane anesthesia. Charles L. Burstein and Bruno A. Marangoni. *Proc.*

Soc. Exptl. Biol. Med. **43**, 210–12(1940).—In dogs anesthetized with cyclopropane 60% developed ventricular fibrillation after injection of one test dose of adrenaline. This was prevented by injection of 5 mg./kg. of procaine. L. E. Gilson

A biological assay method for strychnine in a case of parricidal poisoning. Romulo Guevara, Patrocinio Valenzuela and Guillermo Quibilan. *Rev. filipina med. farm.* **30**, 505–13(1939).—The amt. of strychnine in the contents of a human stomach was estd. by detg. the smallest quantity that would produce convulsions when injected into the ventral lymph sac of a Philippine frog (*Rana vittigera* Wiegmann). This dose corresponds to 0.001–0.0015 mg. strychnine sulfate per g. of frog. L. E. Gilson

Subacute yellow atrophy of the liver due to solvent. Leo E. Braunstein. *J. Am. Med. Assoc.* **114**, 136–8 (1940).—A case of liver damage due to continual exposure to a petroleum distillate, b. 152–78°, is reported. F. P. Griffiths

The use of 2-methyl-1,4-naphthoquinone (a synthetic vitamin K substitute). Jonathan E. Rhoads and Maurice T. Fliegelman. *J. Am. Med. Assoc.* **114**, 400–1(1940).—The use of 2-methyl-1,4-naphthoquinone in doses of 1–4 mg. daily was effective in the treatment of prothrombin deficiency. F. P. Griffiths

Ascorbic acid in experimental chronic poisoning with vanadium. Francesco Cavalli. *Arch. farmacol. sper.* **68**, 211–13(1939).—Ascorbic acid exerted no demonstrable antidotal effect in chronic vanadium poisoning in guinea pigs. Helen Lee Gruehl

Pharmacological studies on calcium guaiacolglycolate (guaiacolcalcium); therapeutic possibilities. Italo Simon. *Arch. farmacol. sper.* **68**, 214–34(1939).—The m. l. d. of Ca guaiacolglycolate, administered intravenously to rabbits, was 0.0060 g. equiv./kg. It was less toxic to the organism as a whole than guaiacol and about equiv. in toxicity, with respect to Ca salts, to Ca lactate. It was water-sol. and could be sterilized without alteration. The indications were that it was a safe therapeutic agent to replace Ca salts or guaiacol. Helen Lee Gruehl

Effect of zinc bromide on blood sugar of normal and diabetic persons with and without insulin. Antonio Delia and Edgardo Rucci. *Arch. studio fisiopatol. clin. ricambio* **7**, 317–30(1939).—$ZnBr_2$ caused hypoglucemia in diabetic but not in normal individuals. It caused a loss of the hypoglucemic power of insulin when injected into diabetic persons receiving insulin. It favorably influenced blood and urine sugar in diabetic persons on a const. diet. Helen Lee Gruehl

Succinic acid and work in diabetic persons. Carmine Antonio Vesce. *Arch. studio fisiopatol. clin. ricambio* **7**, 331–50(1939).—In 4 diabetic persons the administration of succinic acid during controlled work caused slight and insignificant changes in glucemia and glucosuria and a const. diminution of ketonemia and ketonuria. Helen Lee Gruehl

Some effects of nicotinic acid. G. Sotgiù and L. Romaro. *Atti soc. med. chir. Padova* **17**, 214–18(1939).—Nicotinic acid had no effect on blood sugar or glutathione and moderately increased oxalemia and oxaluria. It diminished chloremia and moderately increased chloruria, increased the alk. reserve and diuresis with practically no effect on porphyrinuria. It caused vasodilation, stimulated gastric secretion and in some instances produced gastric upsets and loss of appetite. Helen Lee Gruehl

Effects of eserine, acetylcholine and atropine on the electrocorticogram. Frederick R. Miller, G. W. Stavraky and G. A. Woonton. *J. Neurophysiol.* **3**, 131–8 (1940).—In the cat and rabbit, application to the cortex of min. amts. of 1% eserine (I) caused a reduction in amplitude of the slow waves and the large fast waves of the electrocorticogram; these changes indicated cortical stimulation, since they were assocd. with motor effects. Application to the cortex of $1:10^6$–1% acetylcholine (II) without previous I treatment evoked potential changes comparable with, though weaker than, those due to I. Application of 0.1–1% II after I evoked the I-II spikes; assocd. motor effects showed that the spikes indicated cortical stimulation; I after II was ineffective. Atropinization of the animal precluded induction of the I-II spikes and motor effects. Pilocarpine locally was inert toward the electrocorticogram; and did not sensitize the cortex to II. The drug effects were not due to pH changes. I and II are believed to stimulate or facilitate synapses; I is a synaptic sensitizer for II. The synaptic action of I may be partly direct and partly due to its inhibition of cholinesterase. Potential changes from I are believed due to unequal stimulation of synapses with consequent asynchronous firing of neurons. The I-II spikes are believed due to powerful synaptic stimulation with synchronization of many neurons. It is postulated that, in consequence of stimulation of synapses by I and II, repetitive impulses are initiated or accelerated across these junctions. Marion Horn

The evolution of the vascular system. IV. I. Hel'man and S. Braun. *Arch. sci. biol.* (U. S. S. R.) **44**, No. 3, 87–102(in English, 102)(1936).—The effect of the inhalation of amyl nitrite was studied in children (4–15 yrs.), adults (22–35 yrs.) and old people (61–93 yrs.) with the aid of an electrocardiograph. In the 1st 2 cases an increase in the amplitude of the P waves was found in 37 and 50% (resp.) of the cases, a decrease and a smoothing out of the *T* wave in 86 and 92%, and changes in the direction of the *ST* interval (which falls below the base line) in 52 and 43%. In the 3rd group these changes were less frequent and considerably less pronounced. The changes were of extremely short duration. Histamine in doses of 0.5 cc. of 1 mg. % solns. given subcutaneously to children and old people caused hyperemia of identical intensity, but in the latter group it began somewhat later and lasted longer. S. A. K.

The influence of capillary-active substances on the effect of vagus stimulation. G. I. Tsobkallo. *Arch. sci. biol.* (U. S. S. R.) **46**, No. 1, 88–105(in English, 105)(1937). Some correlation was observed between the effect of vagus stimulation and the capacity to lower the interfacial tension of paraffin oil-aq. solns. No correlation was found in the case of the surface tension of the solns. The ability of vagomimetic drugs to lower the tension of the paraffin oil-aq. soln. interface increases in the order acetylcholine (I), arecoline, pilocarpine, scopolamine, atropine and physostigmine. Choline and I do not change the surface tension at the air-aq. soln. interface, while the other drugs have only a slight lowering effect. S. A. Karjala

The effect of procaine blockade on the biochemical indexes in ulcerous patients. S. V. Zakharov. *Arch. sci. biol.* (U. S. S. R.) **53**, No. 2–3, 23–31(in English, 31)(1939).—The glutathione content of the blood of patients with stomach and duodenal ulcers increases by 2–7 mg. % in 1–3 days after novocaine blockade. Catalase activity is increased, and the amt. of incompletely oxidized org. substances (detd. by titration of the urine with $KMnO_4$) excreted with urea decreases by 2–3 times. S. A. K.

The effect of intravenous injections of arginine on urea formation. L. S. Shvarts and M. I. Krynskiĭ. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 44–9(in English, 49)(1939).—The intravenous injection of 1 g. of arginine or glycine into acute or chronic hepatitis patients causes an increase in blood urea that is slight compared with that seen in subjects with normal livers and this may be used as a diagnostic measure. S. A. Karjala

The distribution of bromine in the organism after the administration of bromides. I. The distribution of bromine between the brain and blood in the quiescent organism and after excitation with camphor. Ya. A. Epshteĭn. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 2, 50–6 (in English, 56)(1939).—The ratio of blood Cl to brain Cl in white mice is 2.33. The injection of 136 mg./kg. body wt. of NaBr yielded a blood Br to brain Br ratio of 3.91 within 1.5 hrs. This remained almost const. for 10 days, during which 4 addnl. doses of NaBr were given. Brain excitation by the hypodermal injection of 0.2 cc. of 20% camphor/25 g. body wt. simultaneously with NaBr did not change this ratio. **II. Changes in the chemical**

composition of the gastric juice caused by the administration of bromides. *Ibid.* **56**, No. 1, 59–68(in English, 68).—The administration of 5 g./day of NaBr to dogs for 8–9 days caused an increase in gastric juice secretion, and an increase in the free and total acidity, total halogen and liberated K. The concn. of liberated K was higher in the more acid juices. The results suggest that gastric juice secretion is a phenomenon of membrane equil., and that the increases observed are due to the lower hydration and greater mobility of Br^- and K^+. S. A. Karjala 1

Toxic enteritis (changes in the intestinal mucosa caused by arsenic poisoning). T. A. Sinitsina. *Arch. sci. biol.* (U. S. S. R.) **56**, No. 1, 34–42(in English, 42) (1939).—The disintegration of the cells of the intestinal mucosa as a result of As poisoning shows no relation to the lesion of the epithelium. An appreciable disintegration of the lymphoid elements of the intestinal mucosa is not accompanied by appreciable emergence of leucocytes from the vessels. S. A. Karjala 2

The biochemistry of the adrenal system and of adrenaline. I. The "binding" of adrenaline by substances with aldehyde and ketone functions and by biocolloids. A. M. Utevskiĭ and N. S. Levantseva. *Bull. biol. méd. exptl. U. S. S. R.* **5**, 75–8(1938)(in English).—To a $1\cdot10^{-4}$ soln. of adrenaline (I) at 37° were added varying proportions of HCHO, AcH, pyruvic acid and Me_2CO at pH 7.0. After 60 min. the presence of free I was detd. by the Bailly and Vulpian (colorimetric) reactions. HCHO in concns. of $1\cdot10^{-2}$ to $1\cdot10^{-4}$ "bound" I completely, but in $1\cdot10^{-5}$ no binding occurred. All the others as well as glyceraldehyde failed to show a binding action at any concn. There is no direct action of lactic acid (II) on I, but II favors the binding of I by proteins to some extent. **II. Restitution of the "tissue concentration" of adrenaline in adrenal glands poisoned by cyanides and monoiodoacetate.** A. M. Utevskiĭ and V. O. Osinskaya. *Ibid.* 78–81. The "tissue concns." of I (the amt. in 1 g. of adrenal medullary substance) in the right and left glands of a single animal are almost identical as detd. by colorimetric methods. With 1 of a pair of glands as a control, the other was isolated and allowed to "work" (perfusion) for 3 hrs., during which it liberated 0.64–2.32 mg. of I into the perfusion soln. and left a tissue concn. in the gland of −0.42 to +1.41 mg. as compared with the control. The generation of I then was 0.42–2.38 mg. The addn. of cyanides to the perfusion liquid causes an increase in secreted I to 1.12–4.39 mg., but with a considerably decreased tissue concn., yielding 0.94–2.40 mg. of generated I. The addn. of CH_2ICOOH (III) causes an increase in secreted I to 1.56–5.28 mg. with practically complete restitution of the tissue concn., resulting in 2.26–4.72 mg. of generated I. It is suggested that the action of III results in a decrease in the concn. of II in the glands, thus facilitating the liberation of I bound to protein. The addn. of II (as Na salt) to the perfusion liquid leads to a diminution of I secretion by the gland and to a simultaneous decrease in the tissue concn. of I in the gland itself. No check on the colorimetric analysis of I by physiological analyses was made. S. A. Karjala 3

The influence of external temperature, diet and emotion on the pharmacological action of thallium. L. I. Levkovich. *Bull. biol. méd. exptl. U. S. S. R.* **5**, 271–3(1938) (in English).—Sheep and Angora rabbits were given sublethal doses of TlOAc and $TlAl(SO_4)_2.12H_2O$. Variations of temp. as well as local warming and cooling of sep. parts of the skin did not affect the process of exptl. moulting induced by Tl compds. In animals kept at −3° mortality was reduced, no toxic diarrhea was observed and the progress of the toxic process was much slower than at 11 or 24°, but the loss in wt. was greater. A hunger diet begun 1 day after administration of Tl and continued for 5 days caused loss of hair in 46.7%, diarrhea in 96.7 and death in 10.0% of the cases, as contrasted with loss of hair in 3.3% of the cases, with no diarrhea or deaths occurring in the controls on a normal diet. Confinement in pens with dry food led to loss of hair in 66.7%, with strong toxic effects and 15.1% av. loss in wt. Under pasture conditions on the same Tl dosage no loss of hair or deaths were observed in sheep and the wt. loss was only 1.7%. Sheep kept in larger stalls with freedom of movement showed greater resistance to Tl. S. A. Karjala 4

The oxidation-reduction potential of biological fluids under the influence of various gases. V. V. Efimov and L. B. Utevskaya. *Bull. biol. méd. exptl. U. S. S. R.* **5**, 222–5(1938)(in French).—The decrease of E_H, from the value obtained under aerobic conditions, of the blood, serum and cerebrospinal fluid under the influence of N_2, H_2, NH_3 and illuminating gas is 27, 23 and 60; 275, 235 and 110; 88, 35 and 43; and 151, 29 and 34 mv., resp. Thus the O concn. is of importance in studying the deviations of E_H from the normal. S. A. Karjala 5

The treatment of acute hydrogen sulfide poisoning. I. D. Meshenin. *Bull. biol. méd. exptl. U. S. S. R.* **6**, 439–41(1938)(in English).—The injection of a soln. of 0.50% H_2O_2 and 1% $NaHCO_3$ in physiol. saline into dogs in a paralytic state as a result of the injection of lethal doses of Na_2S soln. (4.0–4.6 mg. H_2S/kg. body wt.) led to complete recovery in all 9 cases in which it was tried. S. A. Karjala 6

The mechanism of hydrogen sulfide action. II. Catalase changes in acute hydrogen sulfide intoxication. I. D. Meshenin. *Bull. biol. méd. exptl. U. S. S. R.* **6**, 442–4(1938)(in English); cf. *C. A.* **33**, 2991⁹. —The intravenous injection of H_2S solns. (1.5–3.2 mg./kg. body wt.) into dogs caused cessation of respiration for 1–2 min. with recovery; there was a reduction of the catalase index in the blood and organs in 2, and an increase in 3, cases. Subcutaneous injection caused a decrease in all 5 cases of 9.1–35.5%. Expts. with rats indicated that acute H_2S intoxication is accompanied by a reversible inhibition of blood and tissue catalase. S. A. Karjala 7

The effect of curare on the chemical processes involved in muscular activity. O. I. Fainshmidt and M. T. Dmitrenko. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 157–9 (1939)(in English).—The intraperitoneal injection of 0.5–1.0 cc./kg. body wt. of 1% curare into rabbits causes little variation from the normal in glycogen (I), creatinephosphoric acid (II) and adenosinephosphoric acid (III) in the muscles of resting rabbits. Fatigue in normal muscles causes a decrease in I, II and III to 30, 39 and 70%, resp., of the value before fatigue, with large increases in lactic acid (IV) and H_3PO_4, while in the case of curarized muscles fatigue causes a decrease in I, II and III to 84, 31 and 95%, resp., of the value before fatigue, with smaller increases in IV and H_3PO_4 than in the controls. The working capacity of the curarized muscle is not reduced. The introduction of curare seems to inhibit the energy-producing processes now known by blocking the breakdown of I, II and III. It is suggested that the work of the curarized muscle involves the transformation of other compds. S. A. Karjala 8

The urinary ratio during aniline poisoning (carbon, nitrogen and the carbon-nitrogen ratio). S. N. Sinitsyn. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 160–3(1939)(in German); cf. *C. A.* **34**, 4958.—The C/N ratio of the urine of normal dogs is 0.78, while that of the urine of dogs receiving 0.03–0.14 g./kg. body wt. of $PhNH_2$ was 0.80–1.06. In healthy human beings the av. C/N ratio of the urine is 0.86, but in cases of $PhNH_2$ poisoning it reaches 1 or over. S. A. Karjala 9

The action of adrenaline and morphine on gastric secretion in hogs. F. S. Medyakov. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 170–1(1939)(in German).—The injection of 1–2 mg. of adrenaline into hogs results in a strong inhibition of gastric secretion during the 1st hr., with slightly less inhibition during the 2nd hr. after injection. The injection of 0.06 g. of morphine (I) completely inhibits secretion for 1–2 hrs., while 0.01–0.02 g. causes strong but not complete inhibition. After injection of I the juice has an alk. reaction and has a digestive power (Mett) of 0. S. A. Karjala 10

The effect of atropine, adrenaline and morphine on the activity of the parotid glands of the pig. F. S. Medyakov and S. B. Gurak. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 172–4(1939)(in English).—Hypodermal injection of 1 cc. of 1% atropine into pigs caused inhibition of parotid

secretion for 4–4.5 hrs. Adrenaline in doses of 1–3 mg. had no effect. Morphine in doses of 6 cc. of 1% soln. caused a diminution in salivary secretion, possibly as a result of the over-excitation of the central nervous system. S. A. Karjala

The effect of tetrahydro-β-naphthylamine on the salivary glands. I. I. S. Aleksandrov. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 255-7(1939)(in English).—The injection of 5 mg./kg. body wt. of tetrahydro-β-naphthylamine (I) in 0.05% soln. in vegetable oil caused an immediate increase in salivary secretion from the submaxillary and sublingual glands which reached a max. in 70 min. No increase in the secretion of the parotid gland was observed, although the feeding of meal and biscuit powder after I injection caused normal secretion by this gland. The injection of pilocarpine (II) caused approx. equal salivation from all 3 glands. Simultaneous injection of I and II gave less total secretion than I alone. II. *Ibid.* 258-63(in English).—The *per rectum* administration of 0.2 g./kg. body wt. of chloral hydrate to dogs causes a marked reduction in salivary secretion. Severance of the superior cervical ganglion after injection of I does not decrease secretion, but a marked decrease was observed after severance of the tympanic cords. I seems to affect the central part of the secretory app. of the submaxillary and sublingual glands, the impulses being transmitted through the chorda tympani. The percentages of solid, inorg. and org. residues in the saliva before, and 60, 120 and 180 min. after I injection were 1.003, 0.737 and 0.271; 1.124, 0.914 and 0.201; 1.231, 0.966 and 0.265; and 0.774, 0.571 and 0.203%, resp. S. A. Karjala

The rate of penetration and diffusion of acetylcholine in the tissues. I. A. Edel'shtein. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 266–8(1939)(in English). -The application of 1:1000 solns. of acetylcholine (I) to the exposed bifurcation of the common carotid artery and to its trunk at the clavicular level causes a drop in blood pressure within 12 sec. Upon application of I to the fascia lata and the fascia propria of the anterior femoral muscles the reaction is observed in 21 sec. These periods are taken as the time necessary for I to penetrate and diffuse through the tissues. S. A. Karjala

The sensitivity of the heart to cardiac glucosides in anoxemia. A. I. Cherkes and E. S. Rosovskaya. *J. Physiol.* (U. S. S. R.) **25**, 556–68(in English, 568)(1938). -Anoxia in dogs results in an increased sensitivity to strophanthin G (I) and a considerably less marked sensitivity to digitoxin (II), when administered intravenously. The elimination of I is delayed, its curve resembling that of II, the elimination of which is unaltered as compared with normal animals. S. A. Karjala

The control of respiratory movements. II. Alterations in respiration through the action of calcium, potassium, pilocarpine, atropine and morphine. M. Sergievskiĭ, N. Ostroumov and A. Golovin. *J. Physiol.* (U. S. S. R.) **25**, 685–94(in English, 694)(1938). -The suboccipital injection of KCl into cats increases pulmonary ventilation and reduces the inhibitory effect of stimulation of the centripetal superior laryngeal and vagal fibers, while $CaCl_2$, atropine and morphine by the same method of injection have the reverse effect in each case. S. A. Karjala

Distribution of alcohol in the organs. F. Kunkele. *Deut. Z. ges. gerichtl. Med.* **31**, 253–5(1939).—Studies on blood, cerebrospinal fluid, urine, bile and prostate, seminal vesicle and testes secretions showed generally that the alc. content varied directly with the amt. of liquid in the tissue. Frances Krasnow

Relation of blood alcohol, degree of drunkenness, and age. W. Deckert. *Deut. Z. ges. gerichtl. Med.* **32**, 51–62(1939).—People below 30 years of age possess a greater tolerance than older individuals. Blood alc., which is usually low in the younger group, increases as the age of the subject increases. Frances Krasnow

Herpes simplex encephalitis in rabbits. I. The therapeutic effect of vitamin C, sulfanilamide and pitressin. James Flexner, Maurice Chassin and Irving S. Wright. *J. Infectious Diseases* **66**, 30–2(1940).—The data obtained point to the inefficacy of vitamin C, pitressin and sulfanilamide as therapeutic agents in herpes simplex encephalitis in rabbits. The incidence of paralysis in these rabbits was not decreased by these agents. J. H. Lewis

On the expectorant action of resyl and other guaiacols. W. Ford Connell, Grant M. Johnston and Eldon M. Boyd. *Can. Med. Assoc. J.* **42**, 220–3(1940). -A review. G. H. W. Lucas

Reaction of mouse skin to various reduced and partially oxidized sulfur compounds. Stanley P. Reimann and Gerrit Toennies. *Arch. Path.* **29**, 175–81(1940).—Normal cell proliferation and differentiation are notably stimulated (cf. *C. A.* **26**, 1349, 1657; **28**, 5874[9]) in mouse skin rubbed with thiocresol; cystine disulfoxide and cysteine sulfinic acid act similarly though to a less extent. *dl*-Methionine, methionine sulfoxide and cystine are ineffective (cf. *C. A.* **30**, 3842[3], Toennies and Kolb, *C. A.* **33**, 5350[9]). This is interpreted on the basis of —SH liberation. Cystine being ineffective it is believed methionine is not converted to the effective (cf. Brunsting and Simonsen, *J. Am. Med. Assoc.* **101**, 1937(1933)) cysteine by skin. Failure of cystine disulfoxide, cysteine sulfinic acid and methionine sulfoxide to inhibit proliferation (cf. *C. A.* **25**, 977) is laid to their reaction with sulfhydryl groups already present to form —SS—. J. McAfee

Effect of *dl*-methionine and *l*-cysteine on the cleavage rate of mammalian eggs. Bernard J. Miller and Stanley P. Reimann. *Arch. Path.* **29**, 181–8(1940). -As detd. by measurement of the diam. of the cell mass and by the no. of blastomeres of rabbit ova *dl*-methionine and *l*-cysteine stimulate proliferative growth. 0.25 mg./ml. cysteine is more effective than 0.5 mg./ml. J. McAfee

The use of acaprin in the treatment of splenomegaly in chronic malaria. I. Radvan. *Presse méd.* **47**, 1143–6(1939). -Acaprin is a deriv. of 6-aminoquinoline. It is used in solns. of 5 and 0.5% and in doses of 1 and 5 cc. The max. dose is 1 mg. per kg. given subcutaneously; 2–5 injections are given with 2 to 3 days intervals. Beneficial effects in man are limited to cases of splenomegaly. By-effects are feeling of cold, sweating, salivation, inability to retain urine and feces, contraction of the pupils, increase of arterial pressure and hyperglycemia, but all these symptoms are of benign character. The therapeutic effects are rapid reduction of the spleen, subsidence of pain and anemia and increase in wt. A. E. Meyer

Bee venom. Leon Binet and M. Burstein. *Presse méd.* **47**, 1177–8(1939). -Bee venom is hemolytic, delays blood coagulation and causes an increase in blood sugar. It reduces the arterial pressure. In the guinea pig it causes bronchial spasm. Glutathione and Na thiolactate decrease the toxicity of the venom at pH values higher than 7. A. E. Meyer

Treatment of carbon monoxide poisoning. Leon Binet. *Presse méd.* **47**, 1500–1(1939). Inhalation of O_2 is the most efficacious method. Methylene blue is a valuable adjuvant. Glutathione is without effect. $Na_2S_2O_4$ proved to be of some value in the intoxication of fishes with illuminating gas, but it seemed that the HCN contained in the gas was the chief toxic agent. A. E. Meyer

Parenteral sulfapyridine; the intravenous use of sodium sulfapyridine and report of clinical and laboratory observations on the use of glucose-sulfapyridine solutions. Maxwell Finland, Francis C. Lowell, Wm. Spring, Jr., and F. H. Laskey Taylor. *Ann. Internal Med.* **13**, 1105–20(1940). -A highly concd. soln. of sulfapyridine in 50% glucose was nontoxic when given parenterally, but was practically inert. When given orally such a soln. behaved like sulfapyridine except that its absorption was delayed. Na sulfapyridine given intravenously has therapeutic value but may produce serious toxic reactions. 12 references. John T. Myers

The treatment of lobar pneumonia with sulfapyridine and sodium sulfapyridine, with observations on effective blood levels. Theodore J. Abernethy, Harry F. Dowling and Clarence R. Hartman. *Ann. Internal Med.* **13**, 1121–37(1940).—Patients in whom a blood level of 6 mg. % or more was maintained gave a better clinical response. Intravenous injection of Na sulfapyridine is

useful in severe cases, as the blood level can be raised quickly. The mortality in 135 cases was 11.1%. 18 references. John T. Myers

Thromboangiitis obliterans. Treatment with sodium tetrathionate and sodium thiosulfate. Frank V. Theis and M. R. Freeland. *Arch. Surg.* **40**, 190–207(1940); cf. *C. A.* **33**, 2976⁶. Intravenous injections of $Na_2S_4O_6$ and $Na_2S_2O_3$ were usually followed by increased peripheral temps., decreased pulse rate and reduction in blood pressure. These responses were assocd. with changes in O satn. of the arterial and venous bloods. 27 references. John T. Myers

Hexamine insulin. Juvenile type of diabetes treated with hexamethylenetetramine-insulin compound giving rapid and sustained action. Henry M. Feinblatt, Edgar A. Ferguson and Barnett Alpert. *Endocrinology* **26**, 137–43(1940). A new clear insulin compd. with both immediate and sustained effects is described. A single dose can be substituted for 2–4 divided doses of standard insulin. One dose of this new insulin compd. produces a curve similar to the one produced by 4 divided doses of standard insulin but with a decided constriction in the range fluctuation of blood sugar. The shock experienced with this prepn. is comparable with that of standard insulin and responds promptly to the ingestion of carbohydrates. Felix Saunders

Increased duration of insulin action by the use of protamine zinc insulin in pellet form. Jerome Mark and Gerson R. Biskind. *Endocrinology* **26**, 444–8(1940).—Pellets prepd. by compressing a mixt. of 4 parts of cryst. Zn insulin and 1 part of protamine, contg. the equiv. of 13.88 units of insulin, were administered subcutaneously to depancreatized dogs. These pellets produced a marked lowering of blood sugar for from 11 to 100 hrs. Two larger pellets of this mixt., contg. 261 and 1012 units, resp., caused a rapid fall in blood sugar and hypoglucemic shock within 24 hrs. Pellets of cryst. Zn insulin did not show a prolongation of hypoglucemic action. Pellets prepd. from a mixt. of equal parts of cryst. Zn insulin and protamine were not as effective in lowering blood sugar as the pellets prepd. from the 4:1 mixt. The ppt. from com. protamine Zn insulin was centrifuged, dried and compressed into a pellet, which was inactive. When this type of pellet was redissolved, the soln. showed hypoglucemic activity. The active pellets of the 4:1 mixt. produced a marked local edema at the site of implantation. The 2 larger pellets fragmented as they were absorbed. Felix Saunders

Work performance of adrenalectomized rats treated with corticosterone and chemically related compounds. D. J. Ingle. *Endocrinology* **26**, 172–7(1940). Corticosterone, desoxycorticosterone, 17-hydroxy-11-dehydrocorticosterone, 11-dehydrocorticosterone and 17-hydroxycorticosterone will maintain the work capacity of adrenalectomized rats. Little or no effect is obtained by the administration of desoxycorticosterone. A wide discrepancy was noted between the apparent activities of these compds. as judged by the effect on work and the maintenance of life in adrenalectomized animals. This discrepancy may be due either to a qual. difference in the biol. effects or to differences in their rates of utilization. Reduction of the ethylene bond ($C_{1,2}$) in 17-hydroxy-11-dehydrocorticosterone destroys its activity. The property of maintaining the work capacity of adrenalectomized rats is not shown by progesterone, ethinyltestosterone, testosterone, testosterone propionate, estradiol benzoate and stilbestrol. Felix Saunders

Pharmacodynamic effects of testosterone propionate on tubal contractions (oviduct of rabbit) determined by carbon dioxide insufflation. I. C. Rubin and A. M. Davids. *Endocrinology* **26**, 523–5(1940). Testosterone propionate has an inhibitory effect on the tubal muscle, diminishing its general tonicity and the amplitude of the contractions. Felix Saunders

Mechanism and treatment of premenstrual distress with ammonium chloride. J. P. Greenhill and S. C. Freed. *Endocrinology* **26**, 529–31(1940). It is postulated that the symptoms which occur in many women premenstrually result from the increase in extracellular fluid following Na retention in the various tissues of the body. Therapy with NH_4Cl for the purpose of removing extracellular fluid thus formed is effective in relieving the premenstrual distress or tension. Felix Saunders

"Degree of saturation" as a factor affecting the inhibition of cell respiration by cyanide or carbon monoxide. Kenneth C. Fisher. *J. Cellular Comp. Physiol.* **15**, 122–4 (1940).—F. discusses the fallacy in certain math. equations used in detg. the effect of inhibitors on cell respiration. Felix Saunders

Effect of subcutaneous implantation of adrenaline tablets on blood sugar and milk composition in lactating ruminants. A. C. Bottomley, S. J. Folley, F. H. A. Walker and H. M. Scott Watson. *J. Endocrinol.* **1**, 287–99(1939).—Subcutaneous implantation of adrenaline tablets into goats and a cow maintains hyperglucemia for several hrs. (at least 42 in 2 cases). Blood lactic acid and lactose increase during the same period. In no case was the milk yield increased, while in 3 expts. it fell, evidently because of trauma assocd. with the implantation. No uniform effects on milk fat were found. The arterial blood lactic acid in the normal lactating goat ranges from 5.4 to 15.0 mg. %. Felix Saunders

Silver and the organism. Wolfgang Heubner. *Kolloid-Z.* **89**, 110–15(1939).—Metallic Ag was implanted in the epidermis or subcutaneous tissue of the ear of rabbits. After several weeks or months 2 kinds of crystals could be observed on the surface of the metal, AgCl and Ag_2S. In the course of time (several years) Ag_2S was found distributed in the tissues around the site of implantation. Felix Saunders

Theory of the potential action of poisons in pharmacology. W. Laubender. *Kolloid-Z.* **89**, 287–90(1939). A discussion. Felix Saunders

The basal radioactivity of human blood and its significance in the problem of radium poisoning. Adolf Krebs. *Kolloid-Z.* **89**, 309–10(1939).—Radioactive material is taken into the body in air, water and food so that the blood has a const. radioactivity equiv. to 10^{-12}–10^{-14} g Ra per cc. This const. amt. should be taken into consideration in Ra therapy and Ra poisoning. F. Saunders

Cortin-like effects of steroid glucosides on potassium. Raymund L. Zwemer and Bertrand E. Lowenstein. *Science* **91**, 75–6(1940).—Cardiac glucosides protect normal animals against K poisoning and lower plasma K level, and prolong life in adrenalectomized animals. Felix Saunders

The effect of glutathione on selenium toxicity. Kenneth P. DuBois, Morris Rhian and Alvin L. Moxon. *Proc. S. Dakota Acad. Sci.* **19**, 71–4(1939). -SH-glutathione protected rats against death from a min. lethal dose of Se given as Na selenite. Walter H. Seegers

A comparative study of liver glycogen values of control, selenium and selenium-arsenic rats. Richard L. Potter, Kenneth P. DuBois and Alvin L. Moxon. *Proc. S. Dakota Acad. Sci.* **19**, 99–106(1939). The livers of rats fed Se contain less glycogen than those of control animals. The effect of Se is abolished by As. Walter H. Seegers

Effect of yeast on the incidence of cirrhosis produced by lead arsenate. Wm. C. Von Glahn and Frederick B. Flinn. *Am. J. Path.* **15**, 771–81(1939).—The incidence in rabbits of hepatic cirrhosis produced by the ingestion of $PbHAsO_4$ was reduced when powd. brewer's yeast was added to the diet. There was no apparent relation between the amt. of hepatic glycogen and the quantity of As in the liver or the incidence of cirrhosis. F. B. S.

Allergy and the photographer. H. W. Greenwood. *Brit. J. Phot.* **86**, 578–80(1939).—"Metol poisoning" is caused by impurities in the metol, of which sym. *N,N*-dimethyl-*p*-phenylenediamine is most usual. The commonest symptoms are those of a weeping eczema, and treatment consists in the application of an ointment contg. ichthyol and H_3BO_3, and the wearing of gloves day and night. *p*-Phenylenediamine and its derivs. are known, by the experience of the fur and hair-dyeing trades, to be toxic to many persons. Chrome sores are due to the

handling of Cr compds. and take the form of ulcers around the finger nails and on the knuckles. C. H. Smith

The influence of prontosil injection on the blood sugar and the morphological changes of liver, spleen, kidney and suprarenal gland of rabbits. Nitizen In and Syobun Kin. *J. Chosen Med. Assoc.* **29**, 2437–42(English abstr. 151)(1939).—Intravenous injections of 0.2–0.8 cc. per kg. body wt. of prontosil decreased the blood sugar of rabbits and the extent and duration of hypoglucemia depending on the amt. of the injection. Daily injections for 6 days produce marked degenerative changes in liver and lesser changes in the other organs. S. Tashiro

The sympathomimetic action of local anesthetics. Jean Tripod. *J. Physiol.* **97**, 289–300(1940). The local anesthetics, butyn, percaine and stovaine, have the following direct sympathomimetic effects: (1) They inhibit the isolated intestine of the rabbit. (2) They inhibit the isolated uterus of the cat. (3) They augment the contractions of the isolated auricles of the rabbit. In addn. they either augment or depress the action of adrenaline on the isolated heart of the cat, on the blood pressure of the spinal cat, on the nictitating membrane of the cat or on the spleen vol. of the cat. E. D. W.

The inhibition of adrenaline oxidation by local anesthetics. Flora J. Philpot. *J. Physiol.* **97**, 301–7(1940); cf. preceding abstr.—Cocaine, procaine, stovaine, butyn and percaine inhibit the amine oxidase of rat and guinea-pig liver by 60–100%. Cocaine, procaine, percaine and ephedrine inhibit cytochrome oxidase and catechol oxidase by 10–25%. Cocaine and procaine do not inhibit xanthine oxidase or the malic and succinic dehydrogenases of heart muscle. Adrenochrome has no physiol. activity on the blood pressure of the spinal cat, the nictitating membrane, virgin cat uterus or isolated cat heart. E. D. Walter

The action in the perfused liver of acetylcholine, sympathomimetic substances and local anesthetics. M. Chakravarti and J. Tripod. *J. Physiol.* **97**, 316–29 (1940). In the perfused liver of the dog evidence was found for 3 effects of adrenaline: (1) opening of the hepatic veins with increased portal inflow and diminished liver vol.; (2) increase of resistance due to constriction of the small vessels from the hepatic artery and portal vein; (3) in the presence of preexisting adrenaline, an increased resistance on the outflow side. When adrenaline is present in the blood, acetylcholine injected into the hepatic artery causes an expansion of liver vol., probably because of increased arterial inflow. Expansion of the liver diminishes the portal flow and the net effect on outflow is a diminution. Tyramine, ephedrine, veritol, synephrine and benzedrine all act like adrenaline, though their effects are more prolonged. Stovaine and cocaine both have a typical adrenaline-like action. Butyn, percaine and procaine have little or no direct action of their own, but all of them enhance the action of adrenaline. E. D. Walter

Effect of acetylcholine, prostigmine, potassium and fatigue on the crossed extensor reflex and on its reflex inhibition in the toad. Clara Torda. *J. Physiol.* **97**, 357–62(1940). E. D. Walter

The influence of diuretics on the osmotic work done and on the efficiency of the isolated kidney of the dog. M. Grace Eggleton, J. R. Pappenheimer and F. R. Winton. *J. Physiol.* **97**, 363–82(1940). E. D. Walter

The production of exophthalmos in the dog by acetylcholine. Charles E. Brunton. *J. Physiol.* **97**, 383–93 (1940).—The main action of acetylcholine in the intact animal is a relaxation of blood vessels. The relaxed vessels are then distended with blood and push the eyeball forwards. E. D. Walter

The disappearance from the blood of intravenously injected insulin. H. K. Goadby and J. S. Richardson. *J. Physiol.* **97**, 417–28(1940).—After the intravenous injection of 40 units of insulin into rabbits, it is possible to show that the circulating blood has a blood sugar-depressing action. By transfusing it into other fasted rabbits, this action is shown to be due to the injected insulin. This action gradually diminishes and disappears at the end of about 90 min. The rate of disappearance is not affected by excluding the liver from the circulation, or by the previous injection of glycotropic hormone of the pituitary gland. Exclusion of the kidneys from the circulation results in a persistence of the insulin action. The liver, therefore, is not responsible for the inactivation or removal of large doses of exogenous insulin from the blood stream; the kidneys are concerned in such a mechanism. E. D. Walter

Chemistry and toxicology of vapors of solvents (Flury) 13 Urea mandelate [renders urine bactericidal] (Mossini) 10.

F. A. GORTNER

Presence of phenoloxidases in certain mucous glands of Nereis irrorata and Nereis pelagica. R. Defretin. *Compt. rend. soc. biol.* **132**, 501–3(1939). L. B. Gilson

Effect of phytohormones on Euglena in relation to light. Alfred M. Elliott. *Trans. Am. Microscop. Soc.* **58**, 385–90(1939); cf. *C. A.* **32**, 5515[1]. A bacteria-free strain of *Euglena gracilis* was treated with the following plant hormones (Merck): γ-3-*N*-indolebutyric acid, 3-indoleacetic acid and α-naphthaleneacetic acid. The cryst. phytohormones were dissolved in glass-distd. H_2O shortly before use to insure max. activity. Two media were employed, (I) a 0.5% soln. of Difco "tryptone" in glass-distd. H_2O, and (II) the same % of org. matter in artificial tap H_2O contg. the following substances: NaCl 0.003, KNO_3 0.002, $CaSO_4$ 0.020, $MgSO_4$ 0.005 g., $FeSO_4$ trace and distd. H_2O 1.0 l. NaOAc (0.2% soln.) was added to increase the available C for more rapid growth. The basic medium was tubed (8.0 cc. to each tube) and sterilized in an autoclave at 15 lbs. pressure for 20 min. The indole compds. were sterilized at 12 lbs. for 30 min. and then added to the exptl. cultures. Control tubes received 1.0 cc. each of sterile distd. water. Both exptl. and control tubes were then inoculated with a well-washed, actively growing suspension of *E. gracilis*. Initial and final pH detns. were made colorimetrically. The numbers of organisms initially present were estd. with a Sedgwick-Rafter counting chamber and a Whipple ocular micrometer. The final count in cultures from I was made with a counting chamber while that from II, where growth was abundant, was made with the protozoöcrit (*C. A.* **32**, 5515[3]). Half the tubes were illuminated by a 100-watt lamp placed 14 in. from the tubes in a const. temp. bath (temp. not given). The other tubes were protected from light by placing them in a light-proof metal container immersed in the same bath. One-third of the tubes were incubated for 3–5 days, 1/3 for 6–10 days and 1/3 for 9–15 days. All were fixed by adding 0.5 cc. of a satd. soln. of trinitrophenol in *N* HCl to each tube. Growth in I exposed to light was not abundant but was sufficient to show moderate acceleration caused by the hormones. Very little growth occurred in the dark. In II there was a pronounced acceleration in growth resulting from hormone addition, the acceleration being particularly marked in the tubes contg. indolebutyric acid and naphthaleneacetic acid. There was a complete absence of stimulating effect of the hormones in the dark. There appears to be a relationship between the presence of *chlorophyll* and phytohormone stimulation of growth in this organism. L. Wilson Greene

The change of proteolytic activity during the embryogeny of Bombyx mori L. N. V. Bromlei. *Uchenye Zap-*

iski Fakul'teta Estestvoznaniya, Moskov. Gosudarst. Pedagogicheskiĭ Inst., Lab. Org. i Biol. Khim. **1938**, No. 3, 3–15; *Khim. Referat. Zhur.* **2**, No. 5, 50(1939).—From the first days of incubation to the moment of the final formation of the embryo the egg contained only proteinase of the cathepsin type which was activated by cysteine with a max. pH of 3.4–4.0. Several days before the breaking of the shell the embryo contained tryptic proteinase, which functions in the intestines of the larva. A comparison of the curves of the hydrolytic activity of cathepsin in the presence of SH groups and of the curves without the SH groups showed that the total amt. of cathepsin did not change during the time of development of the embryo. However, the ability to split the proteins (connected with the activation by the sulfhydryl compds.) was lower in the initial and the final moments of incubation than in the remaining days of the development. W. R. Henn

Changes in histidine taking place in Bombyx mori L. N. S. Demyanovskaya. *Uchenye Zapiski Fakul'teta Estestvoznaniya, Moskov. Gosudarst. Pedagogicheskiĭ Inst., Lab. Org. i Biol. Khim.* **1938**, No. 3, 41–51; *Khim. Referat. Zhur.* **2**, No. 5, 50(1939). A review of literature with references in regard to the biol. transformations of histidine and the enzyme histidase as of 1937. W. R Henn

Tryptophan in Bombyx mori L. S. Ya. Demyanovskiĭ. *Uchenye Zapiski Fakul'teta Estestvoznaniya, Moskov. Gosudarst. Pedagogicheskiĭ Inst., Lab. Org. i Biol. Khim.* **1938**, No. 3, 89–112; *Khim. Referat Zhur.* **2**, No. 5, 50 (1939).—D. detd. the amt. of tryptophan in *Bombyx mori* L. in all stages of development as well as in proteins obtained from it. Tryptophan was detd. colorimetrically according to Furth (*C. A.* **15**, 377) and to May and Rose (*C. A.* **17**, 116), and was sepd. and identified according to Dakin. Tryptophan was present in *Bombyx mori* L. in all stages of development. About 0.3 g. of tryptophan was found in 100 g. of the worms. The amt. present in female *Bombyx mori* L. was always greater than in male, in the body as a whole as well as in the proteins. W. R. Henn

Copper in the organisms and its content in silk worms. M. F. Liozin. *Uchenye Zapiski Fakul'teta Estestvoznaniya, Moskov. Gosudarst. Pedagogicheskiĭ Inst., Lab. Org. i Biol. Khim.* **1938**, No. 3, 131–51; *Khim. Referat. Zhur.* **2**, No. 5, 50(1939). A continuation of the investigations of L. on the mineral compn. of *Bombyx mori* L. and *Morus alba*. The Cu content in silk worms of different ages, in their excretions and in the leaves was detd. by the sulfide colorimetric method. The worms contained 0.0013–0.0022% and the leaves 0.0022–0.0029% of Cu. The constancy of the Cu content in the larvae was due to its continuous supply from the leaves and to the removal of the excess with the excrements. The relative amts. of Cu in the excrements increased with the growth of the larvae. When the larvae were ready to spin the cocoons this increase of Cu was at a max. (increased from 0.0015 to 0.0081%). The amt. of Cu in the summer silk worms was greater than in the autumn silk worms. W. R. H.

The effect of additional feeding with carbohydrates and proteins on the vitality of silk worms. V. A. Rozhdestvenskaya. *Uchenye Zapiski Fakul'teta Estestvoznaniya, Moskov. Gosudarst. Pedagogicheskiĭ Inst., Lab. Org. i Biol. Khim.* **1938**, No. 3, 153–81; *Khim. Referat. Zhur.* **2**, No. 5, 49–50(1939).—Glucose, sucrose and flour from sprouting peas were added in the investigation of the influence of addnl. feeding with carbohydrates and proteins on the vitality of silk worms and on the quality of the silk thread. The addn. of sprouting pea flour in amts. of 1% of the wt. of the fresh leaves consumed daily increased the amt. of the eggs but did not influence the yield of silk. An addn. of 2% of powdered sucrose lowered the vitality of the larvae and increased the wt. of the raw silk cocoon. Powd. glucose gave neg. results in both cases. W. R. Henn

Fate of 3,6-diketoallocholanic acid and of β-3-hydroxy-6-ketoallocholanic acid in the turtle organism. Morihisa Tukamoto. *J. Biochem.* (Japan) **30**, 377–83(1939); cf. *C. A.* **33**, 8747[8].—About 15.5 g. of 3,6-diketoallocholanic acid was administered subcutaneously to turtles and 0.25 g. β-3-hydroxy-6-ketoallocholanic acid (I) was obtained from the urine. When 9.8 g. of I was administered subcutaneously only 0.12 g. of this acid was obtained from the urines. It is concluded that in the turtle a change of the allocholanic to the cholanic acid series does not occur and that there is no transformation of the *trans*-decalin into the *cis*-decalin form. S. Morgulis

Chemistry of snakes. I. The nitrogenous extractives of the snake muscles. Hiroyuki Imamura. *J. Biochem.* (Japan) **30**, 479–90(1939).—The distribution is recorded of taurine, creatinine, methylguanidine, cadaverine, trimethylamine, carnosine, etc. in muscle extractives from 3 different species of snakes. S. Morgulis

Electrolytes in Thyone muscles. H. Burr Steinbach. *J. Cellular Comp. Physiol.* **15**, 1–9(1940).—By using the chloride space as a measure of the extracellular fraction of the tissue, it is shown that Na of *Thyone* muscles is largely extracellular, K is concd. about 17 times, mostly in the cells, and Ca is present in the cells in concn. lower than that of the normal medium. K can be further concd. in cells as the concn. of the medium is increased up to a satn. point when both cells and medium contain about 35 milliequiv. % K. No more K enters the cells if the concn. in the medium is increased above this point. If concns. are calcd. on the basis of water instead of total wt. the cell water concn. is always higher than that of the medium, being 58 milliequiv. % at the satn. point. Ca can leave the cells and can be taken up by them in spite of the fact that the concn. of cell Ca is always lower than that of the medium. At high external concns. there is less Ca in the cells than there is when the medium contains less Ca. The calcd. cell space is remarkably const. even though the tissues are treated with very toxic concns. of Ca or K and even though the chloride space can undergo marked changes, particularly a decrease when the tissue is treated with excess Ca. Felix Saunders

The effect of adrenaline and choline on the heart rate in Daphnia pulex Geer Paavo Suomalainen. *Ann. Zool. Soc. Zool.-Botan. Fennicae Vanamo* **7**, No. 3, 6 pp. (1939).—Adrenaline stimulated the heart rate of the water flea, *Daphnia pulex* Geer. Choline had a contrary effect. The same results are observed in vertebrates. E. W. S.

The effect of adrenaline on the blood-sugar content in Helix pomatia L. Paavo Suomalainen. *Ann. Zool. Soc. Zool.-Botan. Fennicae Vanamo* **7**, No. 4, 1–3(1939).—Adrenaline increased the blood sugar content in *Helix pomatia* as in vertebrates. E. W. Scott

Contraction and action current of toad heart. I. The effect of calcium chloride and potassium chloride in the perfusion fluid. Sei Syuei. *J. Chosen Med. Assoc.* **29**, 2489–500(German abstr. 154–5)(1939).—The effect of variation in $CaCl_2$ and KCl concns. of the perfusion fluid on the contraction and action currents of the toad heart shows that there is no perfect relationship between the two, although when the former stops, the latter disappears. In the cardiogram, the *T* curve suffers more pronounced changes than the *R*. S. Tashiro

The cholinergic nature of the nervous supply to the electrical organ of the torpedo (Torpedo marmorata). W. Feldberg, A. Fessard and D. Nachmansohn. *J. Physiol.* **97**, 3–5P(1940). E. D. Walter

New experiments with the plankton tower. Helga Schulz and Fritz Koczy. *Naturwissenschaften* **27**, 819 (1939).—Expts. are described with a "plankton tower," 12 m. deep, 2 m. diam. Sterilized sea water (quartz lamp) is fed into this as well as culture medium. By use of Biscaya and Goteborg water mixed with 15 l. soil ext. and addn. of 90 g. $NaH_2PO_4 + 12\ H_2O$, 500 g. $NaNO_3$, 100 g. Na_2SiO_3 all sterilized at a 600 l. per hr. rate, a 2.80-m. high culture layer was established, carried on a 30-cm. high fresh-water layer and this in turn floating on a layer of high salt content. The temp. was maintained at 9°. A *Calamydomonas* culture multiplied from 62 cells per cc. to 10.5 times this value, mostly in the upper layers of the culture. The pH was continuously 8.6. The silicate content decreased, mostly because of pptn. of Fe. No trend in phosphate or nitrate fluctuations was found. The

Chlamydomonas culture was preceded by an unsuccessful *Skeletonema* culture which became overgrown by flagellates in 2 weeks time. B. J. C. van der Hoeven

Distribution of free and total ascorbic acid in liver and muscle of Bengal fresh-water fish (Saha) **12**. Proximate analysis of Brit. Columbia herring (Hart, *et al.*) **12**.

12—FOODS

H. A. LEPPER

In memory of Adolf Juckenack. E. Bames, B. Bleyer and J. Grossfeld. *Z. Untersuch. Beythien. *Ibid.* 13-18. **Juckenack's service for food investigation.** J. Grossfeld. *Ibid.* 18-23.—Juckenack's contributions to food investigation are reviewed and discussed under the above titles. M. M. Piskur

"Unsaponifiable matter" in food analysis. J. Grossfeld. *Chem.-Ztg.* **63**, 749-52(1939); cf. *C. A.* **33**, 3012⁴. —G. describes a new method for examn. of unsaponifiable substances, a method which is very quick and requires small quantities of the fat examd. and of the solvent (benzine). Besides the total unsaponifiable matter, this method also gives the content of hydrocarbons. The new procedure is based on treatment of the alc.-aq. soap solns., obtained from the fat or oil, with a small quantity of benzine on one hand, and with a larger quantity of this solvent on the other; on the basis of the yields thereby obtained, the total unsaponifiable matter of the examd. product is calcd. By dissolving the above-mentioned soaps in dil. alc., such mixts. acquire a greatly increased dissolving capacity for sterols and fatty alcs., a capacity which can greatly exceed even that of benzine; at the same time the hydrocarbons go over into the benzine layer. This difference permits the detn. of sterols and fatty alcs. by a simple calcn. G. also discusses the application of the method to detection of addns. of paraffin to fats, detection of olive oil on the basis of the content of squalene, detection of extn.-cocoa-fat and the distinguishing of unsaponifiable substances. 15 references. Edward A. Ackermann

An oxidimetric method for the determination of the calorific content of meals and of foods. D. I. Nandus. *Voprosy Pitaniya* **5**, No. 2, 117-24(1936); *Chem. Zentr* **1938, I**, 4246.—The basis of the method is the detn. of the amt. of O required for the oxidation of the total product investigated and the calcn. from this value of the calorific value with the use of certain coeffs. These coeffs. are 3.52 for carbohydrates, 3.14 for proteins and 3.28 for fats. After the removal of nonedible portions, the food is ground and 2 g. in the case of homogeneous material or 10 g. in the case of nonhomogeneous material is boiled 10-15 min. with 25 cc. 20% KOH. This is then dild. with water to 100 cc. (for the 2-g. sample) or 500 cc. (for the 10-g.). Ten cc. of the mixt. is boiled 10 min. with 50 cc. $KMnO_4$ and H_2SO_4, cooled to 70°, treated with 50 cc. K oxalate and titrated with $KMnO_4$. When the wt. of food is 850 g. and the $KMnO_4$ consumption 6 cc. then the calorific content is calcd. as $6 \times 850 \times 0.01 \times 3.4/0.2 = 867$ cal.
W. A. Moore

Combined ascorbic acid in plant foodstuffs. I. Jatindra Chandra Pal and B. C. Guha. *J. Indian Chem. Soc.* **16**, 481-95(1939).—A 10-g. sample of finely minced cabbage (I) was ground up with sand under 20% Cl_3CCO_2H, dild., centrifuged, made up to 100 cc. and its ascorbic acid (II) content was estd. by titration with indophenol. Another 10-g. sample was boiled in H_2O in air for 5 min. previous to extn. and estn. A similar estn. was made on a sample boiled in H_2O in N for 5 min. The av. percentage increases in II are 26.5 in air and 40.6 in N. Similar samples were estd. by titration, by titration after addn. of 1 cc. of *M* HCHO to the dye, and by titration after treating the ext. with $Hg(OAc)_2$. Samples were then heated in H_2O in N for 4 min. prior to making up and estg. by the 3 methods indicated. The av. percentage increases on heating for 4 min. in N are 201.4, 204.1 and 153.9, showing that, whatever method of estn. is employed, there is a remarkable increase in the II value after boiling in an atm. of N. The II content of a Cl_3CCO_2H ext. of I does not increase on heating in N; this indicates that the acid does not extract much of the bound II of that it destroys it. A mixt. of 50 g. I and 200 g. Na_2SO_4 was ground and shaken out with abs. alc. Samples were titrated before and after heating for different periods, at different temps., in air and in N. The av. percentage increases, on heating at 100° for 4 min. in air, 4 min. in N, and 10 min. in N (at 40°) are 48.6, 83.3 and 35.0. A mixt of 50 g. I and 200 g. Na_2SO_4 was ground and extd. with ether. The evapd. ext. gave a cream-like residue which was taken up in H_2O and filtered. Aliquot parts were titrated before and after heating in N. No II is extd. from I by ether but the ext. contains *ascorbigen* (III) which invariably produced free II on heating in N at 100° and occasionally on heating at 40°. The ether ext. is free from *ascorbic acid oxidase* (IV) which is present in the aq. ext. Similar expts. with alc. and ether exts. of *Phaseolus mungo* and *Aegle marmelos* demonstrate that the increase of II value which these exts. show on heating is not due to the destruction of IV but is to be ascribed to the presence of II in a combined form, III, sol. in ether, which cleaves in 0.2% HCl at room temp. Ripe and green mangoes are free from III. II Pratul Nath Sen-Gupta and B. C. Guha *Ibid.* 496-504.—Attempts were made to find the most suitable solvent for the extn. of III from dried I. Samples (10 g.) of I were ground with sand, dried at 40° and extd. with ether and benzene, benzene and acetone, benzene and $CHCl_3$ and with $CHCl_3$ and petr. ether. The exts. were evapd. down, taken up in H_2O and heated for 10 min. at 100° in an atm. of N. The reducing substances were estd. by titration with 2,6-dichlorophenol-indophenol. $CHCl_3$ seems to be the best solvent though it does not ext. III completely. It does not dissolve free II. The $CHCl_3$ ext., when heated in N, gives a dye-reducing value, of which 60-70% disappears on treatment with IV. Thus although III is present in the ext., other nonspecific reducing substances are also present in the combined state. The fact that treatment of the $CHCl_3$ ext. with H_2S in the cold does not produce any dye-reducing value shows the absence of dehydroascorbic acid. Biol. estns., in which the curative technique with guinea pigs was used and in which equiv. amts. of an ascorbigen prepn. and pure II were fed, gave comparable results. By extg. I with $CHCl_3$, evapg. and extg. with H_2O, some concn. of II can be effected. C. R. Addinall

Concentration of ascorbigen from cabbage. Baidya Nath Ghosh and B. C. Guha. *J. Indian Chem. Soc.* **16**, 505-10(1939); cf. preceding abstr.—Improved methods for the concn. of ascorbigen (I), combined ascorbic acid, have been devised. Minced cabbage (1 kg.) was pressed and the press juice (II) (600 cc.) was centrifuged and treated with glacial metaphosphoric acid. Only a fraction of the total I was pptd. and the main bulk remained in the filtrate. Other protein-pptg. agents such as CCl_3CO_2H, $(NH_4)_2SO_4$, 50% alc. and 5% HCl were employed without success. $Pb(OAc)_2$ and $Pb(OH)OAc$ were also ineffective. Norit and active charcoal ("carboactive" Schering Kahlbaum) adsorbed 60% of I from fresh II and the main part of I was eluted with alc. $CHCl_3$. The crude I from 1 kg. of fresh cabbage contained 7.43 mg. of reducing substances in a combined state of which 3 mg. consisted of nonsp. reducing material. The crude III gave a strong Molisch reaction and reduced Fehling soln. It contains N and S but no P. It gives glyoxylic acid and Pauly reactions but no xanthoproteic, biuret or Millon's tests. Treatment of crude III with 5% Na_2WO_4 and H_2SO_4 pptd. inert material and all the III originally present appeared in the filtrate. Evapn. *in vacuo* gave a highly hygroscopic brown mass. C. R. A.

Distribution of free and total ascorbic acid in the liver and muscle of Bengal fresh-water fish. K. C. Saha. *J. Indian Chem. Soc.* **16**, 511–14(1939).—Of the edible parts of an animal, the liver is the richest and the muscle the poorest in ascorbic acid (I) (Rudra, *C. A.* **30**, 5313[8]). Guha *et al.* (cf. preceding abstrs.) showed the presence of ascorbigen (II) in many plant foodstuffs. The total I contents of the liver and muscle tissues of 34 kinds of Bengal fish were detd. by hot H_2S treatment followed by oxidation with ascorbic acid oxidase (III). These values were compared with those obtained by the usual CCl_3CO_2H treatment. Samples (10 g.) were minced, suspended in 50 cc. H_2O, satd. with H_2S under reflux for 15 min. and freed from H_2S by a current of CO_2. The suspension (IV) was treated with 2.5 cc. of 20% CCl_3CO_2H, centrifuged and made up to 100 cc. The soln. was titrated against 0.5 cc. of 0.1 *M* 2,6-dichlorophenol-indophenol contg. 1 cc. of glacial AcOH. To est. reducing substances other than I, IV was centrifuged and made up to 100 cc. Aliquots (10 cc.) were incubated with 10 cc. of III (prepd. from 400 g. of white gourd and dissolved in 250 cc. H_2O) for 30 min. at pH 5.6 (2 cc. of acetate buffer). The soln. was then titrated and the total I was estd. from the difference of the 2 readings (with and without oxidase action). From the tabulated results *Anabas testudineus* has the highest I content (30 mg. %) in the muscle, followed by *Pangasius pangasius* and *Labeo rohita*. The concn. of I is highest in the livers of *L. rohita* and *Silonia silundia* (171.1 and 127.4 mg. %, resp.). The difference between total and free I is greater in liver than in muscle. In both tissues the concn. of I decreases as the size of the fish increases. C. R. Addinall

Estimation of vitamin C in foodstuffs. Pratul Nath Sen-Gupta and B. C. Guha. *J. Indian Chem. Soc.* **16**, 549–55(1939); cf. *C. A.* **31**, 5051[4]. The estn. of total ascorbic acid in foodstuffs should include the free ascorbic acid (I), the dehydroascorbic acid (II), which may be formed by the action of ascorbic acid oxidase (III), and ascorbigen (IV), if any. A 10-g. sample of disintegrated plant foodstuff (cabbage, patol (*Trichosanthes dioica*) and onion) was suspended in 50 cc. H_2O, treated with H_2S for 15 min. in the cold and then heated for 15 min. in H_2S on the steam bath. After removal of H_2S by a current of CO_2 or N, the mixt. was treated with 2.5 cc. of 20% CCl_3CO_2H, centrifuged and made up to 100 cc. Aliquots were titrated with 2,6-dichlorophenol-indophenol before and after oxidase treatment at pH 5.6 at 40° for 30 min. with cucumber or white-gourd III. The total ascorbic acid values obtained were higher than those given by the usual method of CCl_3CO_2H extn. Since III progressively deteriorates, dry and aq. prepns. should not be used after 7 and 3 days, resp. Storage in colored bottles does not check deterioration. C. R. Addinall

Effect of cooking on the thiamine content of foods. Elizabeth Aughey and Esther Peterson Daniel. *J. Nutrition* **19**, 285–96(1940).—Thiamine destruction amounted to as much as 22% in some vegetables boiled in water and addnl. amts. up to 15% dissolved in the cooking water. In cases where the cooking water is discarded the total thiamine losses in vegetables may run 20–35%. The addn. of $NaHCO_3$ materially increases the cooking losses. Roasting causes a 43% loss of the thiamine in pork loin, nearly 3 times the loss occasioned by braising. Double-boiler cooking of whole-grain cereals did not destroy thiamine; baking bread caused a 15% loss. The relative values of the different cooked foods in meeting the daily human requirements for thiamine are discussed. C. R. Fellers

Electrolytic determination of tin in food products. N. D. Podobed and F. A. Chigirinskaya. *Voprosy Pitaniya* **7**, No. 6, 142–7(1938); *Khim. Referat. Zhur.* **2**, No. 5, 67(1939).—Destroy org. matter by heating with a mixt. of H_2SO_4 (1:1) and H_2O_2. Det. Sn by electrolysis in a H_2SO_4 soln. in the presence of $H_2C_2O_4$ and NH_4OH with a current strength of 3–4 amp. at 70°. The presence of Cu interferes with the Sn detn. About 3–5 hrs. is required for the complete analysis. The error of the detn. is about ±0.1 mg. W. R. Henn

Effects of naringin and hesperidin on albino rats. Robert H. Wilson and Floyd DeEds. *Food Research* **5**, 89–92(1940).—The continued feeding for 200 days in concns. as high as 1% by wt. in standard diets, gave no evidence of cumulative injury as judged by growth curves, blood-sugar levels, wts. of important viscera and histol. examn. of these tissues. C. R. Fellers

Ripening processes of bread cereals (wheat). Karl Schmorl. *Naturwissenschaften* **27**, 834–7(1939).—A review of the phys. development stages of the wheat grain, including the chem. changes taking place, such as starch formation and protein conversion. B. J. C. v. d. H.

Flour illnesses. H. A. E. v. Hishoeck and D. J. Roux. *Acta Otolaryngol.* **27**, 680–90(1939) (in English).—The incidence of sensitivity to pure proteins obtained from grains is shown by the skin-scratch method to be high in bakers or millers suffering from rhinitis vasomotoria, asthma and eczema. One hundred and fifty normal subjects, 35 allergic patients and 20 eczema patients showed a 1-pos. reaction to flour. Some flour workers are sensitive to proteins from flours with which they do not come in contact. Of 199 persons (50 normal, 50 allergic, 10 eczema cases, 89 flour workers) only 11 (bakers with active eczema) were sensitive by the skin-patch method to NH_4 persulfate improver. The latter sensitivity probably does not persist after healing the eczema, and passive transference tests indicated it to be a toxic reaction distinct from flour sensitization. Conditions resulting from flour illness can be prevented by change of trade or improved working conditions (ventilation, masks, avoidance of contact). Desensitization procedures with active flour proteoses are being investigated and some amelioration has been noted with passage of time. J. McAfee

The antioxidative action of finely milled oat flour on milk. O. F. Garrett. *Milk Plant Monthly* **29**, No. 2, 41–2, 80(1940).—Oat flour exhibited definite antioxidative properties in retarding the development of oxidized flavor in milk induced by contamination with Cu or by exposure to sunlight. The presence of oat flour on the paper from which milk containers were made had an inhibiting effect on the development of sunlight flavor in the milk. Treatment of the paper with oat flour prior to fabricating and paraffining seemed to be the most satisfactory and feasible method of obtaining results. A. H. Johnson

Information on and determination of the antioxidant of oat flour. W. Diemair, R. Strohecker and K. Reuland. *Z. Untersuch. Lebensm.* **79**, 23–42(1940).—Reactions of Strohecker, *et al.* (*C. A.* **32**, 816[9]), v. Fellenberg (*C. A.* **18**, 3731), Kreis (cf. Taufel, *et al.*, *C. A.* **26**, 863) and the peroxide value were used as criteria for progress of oxidation. Addn. of 10 g. of oat flour yielded some protection to olive oil. Distinct protection to peanut, corn, olive, sesame, almond, poppy-seed, soybean and hardened train oils was obtained on addn. of 1–2.25% solvent-extd. oat oil; no retarding of rancidity was obtained on linseed, train-liver and certain soybean-oil samples. Partly rancid oils were not perceptibly influenced. In chromatographic adsorption investigations, with animal charcoal, Spanish earth and clarite as adsorbents and petr. ether and C_6H_6 as solvents, no characteristic zone formation was observed. The active constituent was not adsorbed from the oil. A high P content of the oat oil extd. with petr. ether at first suggested that the antioxidant may be a phosphatide-like material, but tests did not bear this out. Boiling the oil with acid yielded a ppt. and destroyed the antioxidant. Treatment of the petr. ether or the alc.-C_6H_6 ext. of oat flour with EtOH or MeOH or ice-cooled acetone yielded a ppt. contg. an antioxidant substance. The ppt. from this petr. ether ext. gave a much greater antioxidant effect than that from the alc.-C_6H_6 ext. The former contained a 1:17.5 and the latter 1:1.5 P:N ratio. Such a high N content in the most active ppt. suggested the presence of a protein. It gave pos. protein reactions and reduced Fehling soln. The vacuum-dried ppt. was insol. in C_6H_6, ether, $CHCl_3$, MeOH, EtOH, BuOH, AmOH, PrOH, $C_6H_5CH_3$, pentane, H_2O and dil. acids. It was sol. in pyridine and alk. water of pH 12.2. Pepsin

digestion destroyed the antioxidant capacity and split off a fatty material. M. M. Piskur

Colloid chemistry and dietetics. W. Heupke. *Kolloid-Z.* **89**, 291–3(1939).—The colloid chemistry of baking is discussed. Fresh bread is often unsuitable for use for persons with digestive disturbances because it is much more elastic than stale bread and cannot be broken into such fine particles. Fresh bread is therefore more resistant to digestion. In zwiebach the starch is much more broken down to sugars than is the starch in ordinary bread. Felix Saunders

Biochemical transformation of gluten in bread dough. Ugo Pratolongo and Luigi Salto. *Ricerca sci.* **10**, 941–7 (1939).—Preliminary results are given of investigation of the biochem. transformation of gluten in the "ripening" of dough in relation to different chemical, enzymic and technological effects. F. C. Nachod

Microscopic examination of dairy products and their calculations. Hans Edel. *Milk Dealer* **29**, No. 5, 34–5 (1940). A. H. Johnson

Flavors and odors of milk. C. J. Babcock. *13th Ann. Rept. N. Y. State Assoc. Dairy & Milk Inspectors* **1939**, 239–50.—A review. A. H. Johnson

Goat milk and its supervision. J. C. Marquardt. *13th Ann. Rept. N. Y. State Assoc. Dairy & Milk Inspectors* **1939**, 153–66.—Mixed goat milk contains 3 to 5% of fat and 12.7% of solids. The av. lactose content is 3.8%. The chloride content averages 0.21%. This accounts for its salty flavor. The feed requirements to produce a pound of goat milk or cow milk are comparable. A. H. Johnson

Vitamin A in sterilized and irradiated milk. A. Fleisch and A. Schmeper. *Z. Vitaminforsch.* **9**, 330–8(1939). Vitamin A was detd. by means of a spectrophotometer. The vitamin A content of milk was not affected by its antirachitic irradiation. Sweetened condensed milk and milk powder contained more vitamin A than sterile evapd. milk. Sterilization in the presence of the residual air in the can or in an atm. of N had no effect on the content of vitamins A and C in the milk. 13 references. J. S. H.

Preliminary report on the deaeration of market milk. Paul F. Sharp, David B. Hand and E. S. Guthrie. *13th Ann. Rept. N. Y. State Assoc. Dairy & Milk Inspectors* **1939**, 95–104.—A method of detg. the O_2 content of milk is described. It consists in adding an excess of ascorbic acid to the milk and detg. by titration with 2,6-dichlorophenol-indophenol the decrease in ascorbic acid when the rate of oxidation of ascorbic acid is accelerated in the dark and cold by the action of 1 mg. of Cu per l. or by agitating the sample in a closed full tube exposed to Hg-vapor light. It appears that market milk can be deaerated cheaply and easily by a continuous process. Deaerated milk has greatly increased resistance to the development of oxidized flavor and the ascorbic acid remains stable. A. H. J.

Examination of lactose content of normal milk. I. Analytical-chemical examinations. H. C. Jørgensen. *Kgl. Veterinær- og Landbohøjskole, Aarsskr.* **1939**, 130–3 (in English). **II. Statistical treatment of the data.** P. S. Østergaard. *Ibid.* 133–8. The lactose content of 48 samples of milk taken at intervals throughout the year 1938 from the mixed milk of a large number of herds was detd. by Gohr's $K_4Fe(CN)_6$ titration method and by Scheibe's polarimetric method. Two detns. were made by each method, the mean lactose hydrate content by Gohr's method was 4.969% and by Scheibe's method 4.943, the difference being significant. No definite seasonal trend was found. The titration method gave better agreement between duplicates than the polarimetric method, the standard errors being 0.0109 and 0.0185, resp. By combining the results of the two methods the following figures were obtained: lactose hydrate content 4.96%, standard deviation 0.0769, standard error of the mean 0.0111, and coeff. of variation 1.6. Through *Dairy Sci. Abstracts* **1**, No. 1, 86(1939). C. L. B.

Oxygen in milk and its relation to destruction of vitamin C and the development of oxidized flavor. E. S. Guthrie, David B. Hand and Paul F. Sharp. *12th Ann. Rept. N. Y. State Assoc. Dairy & Milk Inspectors* **1938**, 101–5; cf. *C. A.* **33**, 4334[6]. A. H. Johnson

The digestibility of processed milks. Leslie Chambers. *13th Ann. Rept. N. Y. State Dairy & Milk Inspectors* **1939**, 179–94.—Methods of measuring the probable digestibility of milks are discussed. Among such methods are curd tension, curd size and rate of digestion *in vitro*. Data are not yet available by which the true digestibility in the human digestive systems can be detd. by phys., chem. or biol. methods. A. H. Johnson

Losses on boiling milk. Mary Andross. *J. Soc. Chem. Ind.* **58**, 252–4(1939).—By discarding the insol. curd from boiled milk about 10% of the nourishment and 13.29% of the solids are lost. This loss includes 5.75% of the ash; Ca, 13.73%; P, 5.4%; protein, 13.5%; fat, 23.5%; lactose, 1.9%; albumin, 74.13%. R. E. R.

Electrodialysis of skim milk. I. Manufacture of casein. Zirō Katō. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 376(1939). Fresh skim milk (600–650 g.) was electrodialyzed in the middle chamber of a 3-compartment cell, sepd. by thick parchment-paper membranes (0.12 mm.), with Pt electrodes (5 × 10 sq. cm.) suspended in water contained in the outer chambers. Best working conditions were: current, 1 amp./70 sq. cm. of membrane; temp., 30–40°; pptn. at pH 4.3–4.6; and mech. stirring. During electrodialysis the pH falls; when the pH was approx. 5.6–5.7, the particles migrated toward the anode and deposited on the anodic membrane, then when it fell below 4.9–5.0, they migrated toward the cathode and deposited on the cathodic membrane. Approx. 4 hrs. are required for complete pptn. of the casein, the product (yield, 15–17 g.; power consumption, 300 w.-hrs. per kg. skim milk) having 1.8% ash (dry basis) and greater joint strength than most com. caseins. From the results of examn. of 10 different types of membranes, it was found that membranes with neg. charge, such as parchment paper or cellophane, are most suitable. Electrodialysis of 28 g. lactose and 5 g. KCl in 700 cc. of water results in decrease of pH value even with chrome-gelatin-silk as anodic membrane, a result opposite to that obtained with skim milk. **II. Manufacture of lactose.** *Ibid.* 376–7.—The whey remaining after removal of the casein was heated nearly to boiling and filtered to remove a part of the remaining protein. The clear filtrate (600–650 cc.) was electrodialyzed as above, with thick parchment paper or cellophane (0.06 mm.) as the membrane. After 2–3 hrs. the pH was approx. 9; the mixt. was filtered and the clear filtrate concd. under reduced pressure to a solid content of 30–40%. The yield of lactose, which was pptd. from the concd. filtrate by alc., was 22–25 g. (power consumption, 150 w.-hrs. per 600–650 cc. of acidic whey). A sample of lactose obtained on the other hand by addn. of $Ca(OH)_2$ or NaOH soln. to the whey, filtration concn., and pptn. with alc. was yellowish and of poor quality. George Ayers

Phosphatase test for controlling pasteurization of milk. A. Alessandri. *Ann. igiene (sper.)* **48**, 405–17(1938); *Dairy Sci. Abstracts* **1**, No. 1, 107(1939). A. describes various methods of pasteurization adopted in Italy and certain advantages of the Stassano method as used in Rome and Parma and the results of an application of the Kay and Graham qual. test (cf. *C. A.* **29**, 6657[6]) for control of holder pasteurization. Three series of expts. were made with 20 samples each of pasteurized, raw and mixed pasteurized and raw milk. With the first, the test made it possible to see that effective pasteurization had been carried out at 63° for 30 min. With the second the test was satisfactory, but in 6 samples there was a slight blue coloring and lower phosphatase content. With the third, the test showed whether more than 5% of raw milk had been added to pasteurized milk. The method is considered to be rapid, simple and economical and useful also for small farms, and the results important if not yet sensitive enough. C. L. B.

Precision in reading the results of the phosphatase test. F. W. Gilcreas and W. S. Davis. *13th Ann. Rept. N. Y. State Assoc. Dairy & Milk Inspectors* **1939**, 67–78; cf. *C. A.* **34**, 1405[9].—The various methods for making the colorimetric detn. required by the phosphatase test were

studied. The use of permanent standards prepd. from inorg. colored soln. yielded accurate results when the essential conditions of the depth of color soln. and a blue glass plate for reading the colors were observed. Variations from these conditions and lack of sensitivity of the eye to detect color differences led to errors in the results. The use of a photoelec. colorimeter for reading the results eliminated error due to the human element and to fading and other changes in color standards. A simple photoelec. colorimeter known as the "Luximeter" has been developed in which calibration has been made in terms of mg. of phenol per 0.5 ml. of milk and also in terms of enzyme units and for reporting the results of the phosphatase test modified by the New York City Department of Health. This instrument has been found to give results with the official and modified tests that agree closely with those obtained with the permanent color standards.
A. H. Johnson

The effect of pasteurization on the vitamin C content of winter milk. Carl G. Holmberg. *Kgl. Fysiograf. Sallskap. Lund, Forh.* **7**, 105–10(1937)(Pub., 1938); cf. *C. A.* **31**, 5048⁴.—Ascorbic acid (I) in cow milk was detd. by the method of Martini and Bonsignore (*C. A.* **29**, 1121⁶); dehydroascorbic acid (II) in the milk was estd. by subtracting the amt. of I from the value obtained by titration with methylene blue of milk treated with H_2S. In 4 samples of milk kept in black-lacquered bottles the I content about 1 hr. after milking varied from 10.3 to 15.6 mg./l. and the II content from 0.2 to 2.7 mg./l. In 5 samples of milk kept in dark-green bottles the I content varied from 3.4 to 14.4 mg./l. and the II content from 3.0 to 8.4 mg./l. Apparently milk must be completely protected from all light in order to prevent the conversion of I into II. If milk is heated to 70° in total darkness either in air or in light in the absence of O, I remains nearly unchanged while II is almost completely destroyed. Milk should be protected from light during pasteurization to avoid the destruction of vitamin C. Ruth Berggren

The discoloration of methylene blue by Streptococcus thermophilus and Bacterium coli in sterilized milk. T. Matuszewski. *Polish Agr. Forest. Ann.* **39**, 191–218(in English, 218–20)(1937).—The procedure in this study consisted in inoculating definite vols. of sterilized milk with known vols. of active bacterial cultures, adding the dye in the ratio 1:200,000 and detg. the initial and final no. of cells for a definite time of discoloration at a const. temp. of 37–39°. Previous studies in this series include the math. relationship involved in this study (cf. *C. A.* **29**, 6620⁹; **30**, 2273¹, 3105⁸). Two strains of *S. thermophilus* and *B. coli*, resp., were analyzed. It was observed in both species that the moment of discoloration took place at a phase later than the logarithmic one, i. e., at that near the max. stationary phase. This finding was supported both by a high acidity and a distinct decrease of the rate of growth at the end of the discoloration period. The rate of discoloration of methylene blue in the case of *B. coli* proved to be very susceptible to the access of O_2 in such a way that the discoloration only took place when the surface of milk was covered with a layer of paraffin oil. In the tests without the oil the discoloration occurred only in the lowest parts of the milk. Otherwise the O_2 demand of *B. coli* was illustrated by the fact that the organisms gathered in preponderance in the upper parts of the unprotected milk (their motility permitting such migration), and also by a gradual decrease of the rate of activating H, so that the greater the content of O_2 in milk the easier was it activated by the microorganisms. Math. analysis of the data gave curves of *B. coli* with steeper slopes than those of streptococci; this indicates that with greater initial nos. of cells the discoloration is caused sooner by the streptococci, while with smaller initial nos. of cells *B. coli* effects decolorization sooner than streptococci. Av. characteristics of one cell, as computed on the basis of the initial and final no. of cells, times of discoloration, O_2 content in the milk and the increases of lactic acid, have shown that there is a pos. correlation between the particular functions of one cell, i. e., that a greater rate of growth is always followed by more intensive activation of H_2 and a stronger acidification of milk. Especially peculiar was the fact that in the earlier phases of bacterial growth the ratio of the intensity of the H_2 activation to the rate of development of cells was always higher than in the later phase of growth of the bacteria in question. C. T. Ichniowski

The Bacterium coli test in the routine analysis of raw milk. Jan Smit, B. M. Krol and A. J. van Wijk. *A. van Leeuwenhoek J. Microbiol. Serol.* **6**, 1–10(1939–40).—It is important that the test for *Esch. coli* in the routine examn. of milk should be completed in 24 hrs. A large no. of the coliforms found are true *Esch. coli* which have lost their power to form indole. The broth recommended is prepd. from 10 g. peptone (Witte or Difco), 10 g. glutamic acid, 10 g. lactose, 5 g. NaCl, 1 g. K_2HPO_4, 4 g. Na_2CO_3 (anhyd.), 0.26 g. fuchsin and 1.9 g. $Na_2SO_3.7H_2O$ made up to 1 l. with distd. H_2O. Rachel Brown

Mastitis. VII. Relation of bovine mastitis to milk production. G. J. Hucker, Marion S. Reed and E. S. Savage. *N. Y. Agr. Expt. Sta., Tech. Bull.* **244**, 3–97 (1937); cf. *C. A.* **32**, 3840⁴.—The percentage of milk fat was not affected independently of the total production. Total and milk-fat production trends responded similarly to the effects of infection. Conclusion: Streptococcic infections of the udder must be sufficiently advanced that the milk be alk. to bromothymol blue or show evidences of infection by changes in its phys. appearance before a material effect can be noted on production. C. R. Fellers

Infectious bovine mastitis. VII. Characteristics of udder staphylococci. W. N. Plastridge, E. O. Anderson, L. F. Williams and F. J. Weirether. *Conn. (Storrs) Agr. Expt. Sta., Bull.* **231**, 5–60(1939); cf. *C. A.* **31**, 8592⁵.—Av. leucocyte count of 2135 normal samples of milk was 73,000 per cc. with an av. chloride content of 0.121%; comparative figures for 398 samples yielding hemolytic staphylococci are 1,361,000 and 0.151%, resp. While 99.6% of the hemolytic cultures produced acid, or acid and coagulation in litmus milk, 67.7% of the nonhemolytic cultures also possessed this property. The ability of recently isolated udder staphylococci to coagulate human plasma (or rabbit) was more closely related to irritating ability than any other property. 84 references. C. R. Fellers

The hygienic control of acid fermented milk. J. Pisu and M. Guarnacci. *Igiene mod.* **8**, 337–50(1938); *Dairy Sci. Abstracts* **1**, No. 1, 69(1939).—For the hygienic control of yoghurt it is sufficient to test organoleptically, to examine chemically for fixing acidity, to make a direct microscopical examn. with Gram-stained specimens for controlling the acidying flora, and to examine the culture for *B. coli* and possible pathogenic intestinal bacteria. Yoghurt should be a white compact mass, of homogenous appearance, gelatinous consistency, aromatic smell and acid flavor. Its lactic acid content may vary from 0.40 to 1.50% with a normal range of 0.80 to 1.0%.
C. L. B.

Adulteration and constants of ghee. N. S. Doctor and B. N. Banerjee. *J. Univ. Bombay* **8**, Pt. 3, 247–54(1939).—To det. the quality and the purity of ghee, a clarified Indian butter fat, it is necessary to take into consideration the cumulative effect of the phys., chem. and physiol. consts. and the history of the origin of the sample. A no. of these consts. for various kinds of ghee are given in 4 tables. F. E. Brauns

A rapid multiple-color test for the approximation of available chlorine. Harry Scharer. *13th Ann. Rept. N. Y. State Assoc. Dairy & Milk Inspectors* **1939**, 55–66.—A colorimetric test for the approximation of available Cl is presented based on the formation of a meriquinone and a holoquinone of *o*-tolidine dihydrochloride and their intermediate products. Depending on the level of Cl concn., the method yields 4 distinct colors which can be readily distinguished. The method is simple and inexpensive and will distinguish between a hypochlorite and a chloramine.
A. H. Johnson

Factors influencing the physical characteristics of chocolate milk. J. G. Brereton, W. B. Combs and H. Macy. *Milk Dealer* **29**, No. 5, 38, 62–8(1940).—With com. nonsettling chocolate milk prepns. the temp. of the milk at

the time of adding the powder or sirup does not affect the stability provided the agitation is satisfactory and the product does not contain alginate stabilizers. Increasing the temp. of pasteurization decreases the amt. of stabilizer needed to produce a stable chocolate milk. The phys. state of certain stabilizers in water suspension is greatly affected by the presence of relatively low concn. of certain salts. The addn. of small amts. of $CaCl_2$ to milk causes the gelation of purified alginate stabilizers in that milk. Chocolate milks contg. alginate stabilizers tend to thicken on holding at 40°F. When stabilizers are used in the prepn. of chocolate milk, the cacao fat content and the relative fineness of the av. com. cacao did not appear to have any appreciable effect on the stability of the product. A. H. Johnson

Examinations of cream ripening. Søncke Knudsen, S. Nielsen and H. V. Knudsen. *Kgl. Veterinaer- og Landbohøjskole, Aarsskr.* **1939**, 7 20(in Danish with English summary); *Dairy Sci. Abstracts* **1**, No. 1, 61.—The progressive change in pH value during the ripening of cream by starters and the prepn. of starters, under normal conditions of practice in Danish creameries is shown. The effect of variations in ripening temps., the proportion of starter used and the age of the starter are given. Starters show max. activity about 1 hr. after coagulation but the loss in activity after 19 hrs. is not great. The pH values of creams just before churning and their corresponding buttermilks are identical; but titratable acidities, based on creams less fat, show varying and marked falls in the buttermilk owing to loss of CO_2 in churning. Rates of ripening in creams, based on creams less fat, are slightly slower than in the corresponding buttermilks. In starter ripening, bacterial increase and fall in pH value accompany one another fairly closely, but the titratable acidity continues to rise after the bacterial count and pH value have both become stationary. C. L. B.

Thiocyanogen numbers of Danish butter fat. A. Sørensen. *Kgl. Veterinaer- og Landbohøjskole, Aarsskr.* **1939**, 1-6(in German); *Dairy Sci. Abstracts* **1**, No. 1, 94.—Av. figures for 20 samples of Danish butter produced in September, 1937, were thiocyanogen no. 35.7, I no. 39.3, satd. acids 58.6%, oleic acid 37.3% and linoleic 4.2%. Corresponding figures for 10 samples produced in January, 1938, were 26.6, 30.6, 69.2, 26.2 and 4.6, resp. Oiliness and tallowiness induced by storage did not markedly affect these values. C. L. B.

The manufacture of ice cream. Arthur Henry White. *Can. Dept. Agr., Tech. Bull.* **26**, 31 pp (1940).—Review, including compn. and tests. G. G.

Influence of some mix components on the texture of ice cream. W. C. Cole and J. H. Boulware. *J. Dairy Sci.* **23**, 149-57(1940).—The organoleptic test, the microscopic examn., ice-crystal size and dilatometer measurements of the rate of freezing were used as a basis for evaluating the factors contributing to ice-cream texture. An increase in the percentage of milk solids as a result of increasing either the fat or the milk-solids-not-fat improved the smoothness of ice-cream texture, as judged organoleptically, and tended to decrease the size of the ice crystals formed in ice cream. When the milk-solids contents of the samples were maintained essentially the same but the ratio of fat to milk-solid-not-fat varied significantly, the milk-solids-not-fat were more effective than the milk fat in causing the formation of small ice crystals. Under the same conditions the dilatometer data show that the milk-solids-not-fat had a greater influence than did fat in retarding freezing. It is suggested that smaller ice crystals formed in samples with a higher proportion of milk-solids-not-fat may be due to a retarding action of the latter in the growth of ice crystals. An increase in the proportion of fat in ice cream was found to have a greater effect on texture judged organoleptically than it did in reducing the ice-crystal size judged microscopically or in retarding the growth of ice crystals as measured by the dilatometer. When variations in compn. are not too great, in a series of samples, one can expect good correlation between ice-crystal size measured microscopically and smoothness of ice cream judged organoleptically. This relation does not necessarily hold, however, if the proportion of fat to milk-solids-not-fat is very high or very low, possibly because fat in ice cream has a lubricating effect in the mouth, whereas its effect is not nearly so pronounced with milk-solids-not-fat. A. H. J.

The study of methods of application of pH determination in butter sera. C. H. Parsons. *Rept. Res. Comm. Am. Butter Inst.*, **1938**, 1; *Dairy Sci. Abstracts* **1**, No. 1, 95.—The quinhydrone electrode is stated to be more satisfactory than the glass electrode for detg. the pH of butter serum owing to the fragility of the glass electrode and the difficulty of keeping it free from fat. 5000 samples of butter kept at 70°F. for 8 days lost an average of 1 point in score when the pH of the fresh butter was 6.6 to 7.0, and 0.5 point when the pH was 6.7. Salt contents greater than 2% tended to increase the loss of score. C. L. B.

Borated butter. L. Delavelle. *Presse méd.* **47**, 1201 (1939).—The use of boric acid as a preservative of butter is not free from possible danger. The daily consumption of 40 g. of butter would lead to the ingestion of 0.2 g. of boric acid, which approaches the max. dose used in reducing cures. A. E. Meyer

Relationship of acid-number variations to the qualities and flavor defects of commercial butter. E. L. Fouts. *J. Dairy Sci.* **23**, 173-9(1940).—Most samples of unsalted butter increased in acid no. of the fat during holding for 6 days at 21°. When samples of com. unsalted butter were held at 21°, approx. 25% became rancid within 6 days. No close correlation existed between the acid no. of the fat and the quality of com. unsalted butter; butter of good quality often had relatively high acid no., while some rancid samples had relatively low acid no. When samples of com. salted butter were held at 21°, comparatively few samples became rancid in 6 days. A. H. J.

Changes in biacetyl and acetylmethylcarbinol contents of butter at various temperatures. E. A. Prill and B. W. Hammer. *J. Dairy Sci.* **23**, 159-68(1940); cf. *C. A.* **33**, 3905. In general, salted butter contg. about 2.25% salt made with different manufg. procedures showed only relatively slight changes in biacetyl and acetylmethylcarbinol plus biacetyl contents when held frozen or at 36 to 45°F. Even at 70° F. at which temp. chem. deterioration is especially rapid in butter, the contents of these substances were largely retained for considerable periods. With unsalted butter the changes at −10 to 0° F. were relatively slight, but at 36 to 45° F. significant changes occurred, both increases and decreases being involved A. H. Johnson

The blowing of cheese. G. Schwarz, O. Fischer, A. Lembke and H. Jensen. *Vorratspflege u. Lebensmittelforsch* **1**, 399-412(1938); *Dairy Sci. Abstracts* **1**, No. 1, 67(1939). KNO_3 inhibits gas production by coli-aerogenes bacteria in cheese but methylene blue, metol, hydroquinone, and milk-fat globule "membrane substances" increase it. Data are given for the effect of specific substances on the production of CO_2 and H_2 by coli-aerogenes strains in various media, and the results discussed in relation to the fermentation scheme of Tikka. Lactoflavin appears to increase the production of H by aerogenes strains and to decrease that by true coli types. Among other factors favoring H production are the amino acids in a casein digest. C. L. B.

The production of lactic acid from substances other than sugar by Lactobacillus casei. C. C. Thiel. *Proc. Soc. Agr. Bact.* (Nat. Inst. Research Dairying, Shinfield, Reading) **1938**, 38-40; *Dairy Sci. Abstracts* **1**, No. 1, 54.—A strain of *Lactobacillus casei* isolated from Cheddar cheese in New Zealand produced more lactic acid in peptic milk digest and pancreatic and peptic casein digest mediums than could be accounted for by the sugar utilized. Appreciable amts. of lactic acid were produced in casein digest mediums free from sugar. C. L. B.

Removal of markings on eggs. Guglielmo DeSalvo. *Ann. chim. applicata* **29**, 481-4(1939).—Dates, country of origin and other markings stamped on eggs to meet requirements of the laws of various countries are often fraudulently removed. HCl or NaClO solns. remove stamping inks without leaving telltale marks. To detect this fraud a drop of 0.001 *N* soln. of picric acid is allowed

to stand on the eggshell for 10–20 seconds and then washed off with water. A yellow stain remains on unwashed eggs, but no stain is left on eggs treated as above, as the acid or hypochlorite removes the protein film from the surface of the egg. A. W. Contieri

Change in nitrite during storage of nitrite pickle salts. Georg Stamm. *Z. Untersuch. Lebensm.* **78**, 464–70(1939).—Tabulated data show the loss of nitrite occurring in (meat) pickel salts on storage. The losses occurred during dry storage, humid storage and storage in glass bottles, but to a different degree. Results of detns. of nitrite and total N show that the loss could not be attributed to oxidation of nitrite to nitrate by atm. O. S. suggests that the loss is due to volatilization of N oxides and that this may be influenced by impurities in the NaCl used in the mixt. $MgCl_2$ may react with moisture to yield MgO and HCl and N_2O_3 may develop as follows: $2NaNO_2 + 2HCl = 2NaCl + H_2O + N_2O_3$. M. M. Piskur

Fresh fish. I. The role of pH in the preservation of fish. Aristide Nadeau. *J. Fisheries Research Board Can.* **4**, 355–62(1939)(in French).—The effect of pH on the rate of increase of microorganisms in fish was studied in expts. designed to lengthen the period of time during which fresh fish can be stored. The amt. of Me_3N present was used as an index of decompn. (cf. Beatty and Gibbons, *C. A.* **31**, 3581[9]). Fresh fish were cut into fillets, ground and the juice was expressed. Equal amts. of this expressed juice were mixed with lactate, citrate and phosphate buffers and stored at 0° for periods up to 60 days. At intervals during this storage period, Me_3N was detd. in the buffered expressed juice. With lactate buffer, the formation of Me_3N was very rapid above pH 6.6; at pH 6.0 the formation of Me_3N was decreased, and was practically stopped in the range 5.2 to 3.7. Expressed juice buffered in this range developed no disagreeable odor during the 60-day storage period. With phosphate and citrate buffers the pH must be below 5.0 to preserve the expressed juice. Whole fillets cut from fresh fish were also preserved, by immersing the fillets in the buffer solns. until test samples showed that the flesh had attained the desired pH. The fillets were then removed from the buffered solns., placed in parchment paper and stored at 0°. At suitable intervals, samples of the flesh were ground and centrifuged to obtain muscle juice for the Me_3N detn. Phosphate buffers in the pH range 6.2 to 6.4 promoted the decompn. of the fillet. With citrate buffer at pH 4.6 there was but little decompn. during 40 days. Lactate buffers gave the best preservation of the fish fillets; at pH 4.7 there was slightly less decompn. than with a citrate buffer at pH 4.6. From the practical standpoint, however, it is easier to use citrate buffers, since the lactate buffers require longer immersion to bring the fillets to the desired pH. W. Gordon Rose

Proximate analysis of British Columbia herring in relation to season and condition factor. John L. Hart, Albert L. Tester, Desmond Beall and John P. Tully. *J. Fisheries Research Board Can.* **4**, 478–90(1940); cf. *C. A.* **33**, 764[7]. —Analysis of samples of *Clupea pallasii* from different seasons showed the following compn: H_2O 64.2 to 80.2, oil 4.1 to 19.1, protein 10.1 to 16.8% and ash 1.9 to 2.8%. The contents of cans contg. random samples of herring were ground, thoroughly mixed and sampled. Dry wt. was detd. as the residue after 24 hrs. at 98°. The dried samples were ground, redried, and the fat was detd. as the loss of wt. after 4 hrs. of extn. in a Soxhlet app. with CCl_4. The extd. sample was ground to pass an 80-mesh sieve, re-dried, and total N detd. by the Kjeldahl-Gunning-Arnold method. Oil content was highest in the summer, declined during the fall and winter, and fell to a min. after spawning time in early spring. Calorific value of herring varied between 0.94 and 2.41 Cal. per g. From analytical data, the authors conclude that 50% of the energy in lean fish is available when the herring are used on the table and 80% when reduced and used for feeding stock. In fat fish, 59% of the energy is used when fish are eaten fresh or canned and 84% as food for stock. In fish reduced and used for fertilizer, it is likely that all the nitrogenous matter is ultimately in a condition to be used as plant food, i. e., 100%. There was a reciprocal relationship between oil and H_2O content but this is considered due to the method of calcn. A pos. relationship exists between condition factors and oil content, but is considered too loose to be of value for calcg. oil yields. Analysis show that yields of less than 7.4 U. S. gal. per ton are rare and may reach 30 gal. per ton. Maurice M. Rath

Penetrometers for fruit. G. M. Dreosti and P. Wissing. *Union S. Africa Dept. Agr. Forestry, Rept. Low-Temp. Research Lab.* **1937 38**, 271–5(1939).—A preliminary investigation of the limitations of this type of instrument was made. The readings are not proportional to the cross-sectional area of the plunger and the force is not uniformly distributed over the face of the plunger. The exact shape of the plunger face does not affect the readings to any appreciable extent. K. D. Jacob

Control of rots of apples. F. D. Heald. *Wash. Agr. Expt. Sta., Popular Bull.* **158**, 3–8(1939).—The spraying of apple boxes with a NaOCl soln. contg. at least 0.4% available Cl effectively prevents spread of blue mold from the containers. Steam sterilization is also effective. Cleaning solns. to remove Pb and As residues are likewise effective in removing mold spores from the fruit and thus lessening the likelihood of later spoilage. Of these cleansers, Na silicate is most toxic to mold spores, followed by 1% HCl and Na_2CO_3. Apparently field sprays have no effect on the incidence of storage rots in apples. C. R. Fellers

Effects of calcium salts in canning tomatoes. Maurice Siegel. *Canner* **90**, No. 2, 12–13(1939).—The firming action of certain Ca salts on canned tomatoes previously reported by Kertesz (*C. A.* **33**, 9472[7]) is confirmed. Ca lactate and $Ca(OAc)_2$ do not produce a satisfactory firming effect. The presence of NaCl has no effect on the action of sol. Ca salts such as $CaCl_2$. C. R. Fellers

Hydrogen swells in canned fruits. T. P. Hoar. *Canner* **90**, No. 3, 18(1939); cf. *C. A.* **33**, 8549[1], 9245[3].—With the types of steel base tested and fruits packed, the use of Sn plate with a relatively high Cu and low P content will ordinarily double the usual life of the canned foods. The comparative tendency of a can to form H swells may be assessed roughly by a corrosion test of the steel base with a pure citric acid soln. Steel base with high Cu content, up to 0.2%, and also with less than 0.045% P, gave the lowest rate of H swell formation in lacquered-can packs of black currants, gooseberries, loganberries, pluums, raspberries and strawberries. S content within the limits investigated (0.02–0.09%) was without influence. The pack of white cherries was not influenced by the Cu, P or S content of the steel base. C. R. Fellers

Standards for frozen-pack fruits. Paul M. Williams. *Canner* **90**, No. 9, 16–18(1940). C. R. Fellers

Stainless steel in the freezing plant. Claudia Gavrilova. *Canner* **90**, No. 6, 22–3, 26(1940). C. R. Fellers

Application of calcium in the commercial canning of whole tomatoes. Z. I. Kertesz, T. G. Tolman, J. D. Loconti and E. H. Ruyle. *Canner* **90**, No. 12, Pt. 2, 52(1940); cf. *C. A.* **33**, 9472[7].—Peeled tomatoes are dipped in a soln. contg. 2% $CaCl_2$ for 2 min. for obtaining greater firmness. Such tomatoes absorb 150–200 p. p. m. of Ca, with a min. of 76 p. p. m. for best results. The av. Ca content of tomatoes canned under com. conditions with added Ca was 62.2 p. p. m. C. R. Fellers

Effect of added calcium on tomatoes. D. Godfrey. *Canner* **90**, No. 12, Pt. 2, 52–8(1940).—The addn. of Ca to whole canned tomatoes increases their firmness, improves their texture and decreases the loss between put-in to drained wt. NaCl has little effect on the Ca effectiveness. $CaCl_2$ gives good results but cannot be made up readily into tablets because of its hygroscopic nature. The $CaCl_2$ should be added directly to tomato juice used for filling the cans. C. R. Fellers

Application of calcium to canned tomatoes. E. H. Ruyle. *Canner* **90**, No. 12, Pt. 2, 58(1940).—Commercially, the use of NaCl tablets contg. Ca salts is the most convenient procedure for adding Ca compds. to canned tomatoes for the purpose of firming the flesh. C. R. Fellers

Heat penetration in canned tomato juice. H. P.

Stevens. *Canner* **90**, No. 12, Pt. 2, 45–6(1940).—Viscosity of the juice markedly affected heat transfer. Agitation of cans during thermal treatment materially decreased the time required to sterilize tomato juice. Use was made of a Stormer viscometer for viscosity detns. C. R. Fellers

Rate of heat penetration in canned tomato juice. L. J. Frost. *Canner* **90**, No. 12, Pt. 2, 46 8(1940).—Tomato juice is a much slower-heating product than was formerly believed. The Stormer viscometer readings did not correlate well with heat-penetration data on canned tomato juice. Heat-penetration data for different-sized cans are given. C. R. Fellers

Chemical constituents of some fruits grown in British Columbia. F. E. Atkinson and C. C. Strachan. *Sci. Agr.* **20**, 321–8(1940).—The percentages of total sugars were: in apples 10.7–14.7, apricots 9.0, peaches 7 11, Royal Ann, Bing, Lambert and Deacon cherries 14.5, 14.5, 15.0 and 12, resp., prunes 10.0 27.5, grapes 12 25, black, white and red currants 5.3–6, strawberries 5.5 8.5 and red raspberries 9.4 14.2. Data are given on acidity, reducing sugar, sucrose, ash, pectin, pH, tannin and insol. solids. Flotation in brines of different strengths proved an effective means of sepg. the dried fruit on the basis of sugar content. Prunes left on the tree to ripen showed a progressive decrease in acid for several weeks after they had attained max. sugar content. Black currants contained about 1.6% pectin as compared to 0.61% for red or white currants. The sol.-solids content of cherries can be used as a means of detg. the suitability of the fruit for glacéing. Good-quality medium-sweet wines were produced by the following grape varieties: Burgunder, Campbell Early, Muscat Ferdinand de Lesseps, Muscat Ottonel, Portland, Rauschling, Reisling-Sylvaner, Seiber 2838 and Seibel 5279. C. R. Fellers

Prevention of curd in grapefruit juice. Clarence T. Parks. *Canner* **90**, No. 12, Pt. 2, 71–2(1940).—Fruit variety, maturity and sweetening agents had no effect on curd formation. Methods of juice extn. and inclusion of pulp in the juice were likewise without effect. Curd formation and abnormal sepn. of the insol. solids were prevented by adequate heat treatment in canning. Such treatments were (1) flash pasteurization at 190°F., (2) heating to a min. of 185°F. in a kettle and (3) vacuum sterilization by heating to 180°F. for 15 min. The pH values of the grapefruit juice varied from 3.2 to 3.4, with total acidities (citric) of 1.3–1.5%. Time is an essential factor in the development of curd in inadequately pasteurized juice; hence short storage samples may give deceptive results. C. R. Fellers

Physiological studies of lemons in storage. Erston V. Miller and Harold A. Schomer. *J. Agr. Research* **59**, 601–7(1939).—See *C. A.* **33**, 8842[9]. W. H. Ross

Diplodia stem-end rot of lemons controlled with sodium ethyl mercurithiosalicylate. G. H. Godfrey and W. H. Friend. *Science* **91**, 94–5(1940).—Merthiolate in the regular 1:1000 tincture applied as a local stem-end treatment on lemons gives practically perfect stem-end rot control after 2 weeks incubation. During this time the controls rotted to the extent of 60 72%. F. S.

The ascorbic acid (vitamin C) content of six varieties of cantaloupes. M. A. Moseley, Jr., and G. Howard Satterfield. *J. Home Econ.* **32**, 104–7(1940).—Titration expts. on the ascorbic acid content of cantaloupes showed that it decreases with ripeness but has no relation to size. Though there are wide variations in the content of each variety, one variety averaged 49% higher than another. All varieties contained from 20 to more than 30 mg. per 100 g. sample. Amy LeVesconte

Investigation of the vitamin C content of Florida fruits and vegetables. I. Effects of maturation and of cold storage on the vitamin C potency of oranges and grapefruit. R. B. French and O. D. Abbott. *J. Nutrition* **19**, 223–32(1940).—Individual trees produce citrus fruits of fairly uniform ascorbic acid content. However, there is a wide variation in ascorbic acid content among varieties and even in the same variety. There is but little effect on ascorbic acid content due to maturation of oranges. Variations in ascorbic acid content among oranges did not correlate with the different geographical locations in which they were grown. There may be an increase in ascorbic acid during the 1st few weeks of cold storage; after this, the concn. slowly decreases. C. R. Fellers

Color changes in green vegetables—frozen-pack peas and string beans. G. Mackinney and C. A. Weast. *Ind. Eng. Chem.* **32**, 392–5(1940)—Much of the chlorophyll in frozen vegetables changes to pheophytin. This is detd. by the spectroscope and by the sapon. products. Blanching reduces the amt. of color change by removing air and volatile and water-sol. constituents that would react with the chlorophyll. The effect of blanching is less with beans than with peas. Amy LeVesconte

Treatment of corn-canning wastes. H. O. Halvorson, Dale W. Johnson and Henry Tsuchiya. *Canner* **90**, No. 7, 12–24; No. 8, 12–14(1940).—A lagoon, together with a trickling filter, will provide an economical and effective treatment for canning-corn wastes. The B. O. D. of corn-canning wastes ranges from 1200 to 4000 p. p. m., the total solids from 1500 to 8000 p. p. m., total volatile solids from 1400 to 7000 p. p. m. and suspended solids from 300 to 4000 p. p. m. Fresh corn wastes are neutral but they rapidly become acid on standing, developing a pH as low as 3.5. Various expts. are described. C. R. Fellers

Cooking quality of the potato as measured by specific gravity. C. F. Clark, P. M. Lombard and Elizabeth F. Whiteman. *Am. Potato J.* **17**, 38 45(1940).—The use of salt solns. of known densities was found to be a practical method for detg. the d. of potatoes for the purpose of making a preliminary selection for mealiness and cooking quality. Tests on potatoes grown in a single season did not give a sufficiently adequate basis for rating the mealiness of a variety. The mealiness of potatoes depends to a considerable extent on their starch content. K. D. Jacob

Potato growing in Ireland with particular reference to production for industrial purposes. J. P. Drew and D. Deasy. *J. Éire Dept. Agr.* **36**, 205–29(1939).—Data are given on the starch contents of numerous varieties of potatoes grown in Ireland in different yrs. The results indicate that where potatoes are grown for human consumption as well as for industrial purposes the Arran Banner, Arran Consul, Kerr's Pink and Up-to-Date varieties are the most suitable, but when grown solely for industrial purposes the Hellena and the 1934 strain of Parnassia are the best. K. D. Jacob

Methods of canning pumpkin. H. R. Smith. *Canner* **90**, No. 12, Pt. 2, 72–5(1940).—Starch contents are for Conn. field pumpkin 0.5, Boston Marrow squash 1.5 and Golden Delicious squash 6.5%. These variations in starch content greatly influence consistency in the canned product. Penetrometer methods for detg. consistency of canned squash or pumpkin are described. Details of the recommended canning process are given. C. R. F.

The storage of pecans. F. R. Brison. *Texas Pecan Growers' Assoc., Proc. Ann. Meeting* **17**, 21–4(1937).—A discussion of the chem. changes occurring in pecans during storage. K. D. Jacob

Deterioration of catsup and its prevention. C. C. Fowler. *Glass Packer* **19**, 30–2(1940). –Advantages of deaeration are improved color, elimination of "black neck" and greater retention of vitamins. Deaeration equipment is described. C. R. Fellers

Dextrose in the preserving industry. E. H. Wiegand. *Canner* **90**, No. 11, 26–7, 32(1940).—The substitution of 20–35% dextrose in the sugar added to preserves and jams normally improved the natural fruit flavor and decreased the final sweetness of the product. The texture, color and shelf life of the fruits are likewise improved by using about 20% dextrose in the preserves. About 20% of the sugar can be used in frozen-pack fruits to be used later by preservers. C. R. Fellers

A study of the chemistry of coffee. Oscar Ribeiro. *Rev. alimentar* **3**, 193–5(1939).—Fifteen analyses are reported. The figures show nothing that can explain differences in "cup yield" or flavor. O. W. Willcox

Vitamin A and its source, carotene, as a vitally im-

portant factor in artificially dried feeds. Max Nitzsche. *Deut. Zuckerind.* **65**, 59–63(1940).—The carotene loss of artificially dried green fodder is 10–30%. These dried materials are valuable as a vitamin food even after long periods of storage. Carotene losses are much greater by other processes. W. W. Binkley 1

The comparative feeding value for pigs of cereals prepared in the flaked and ground forms. E. J. Sheehy and B. J. Senior. *J. Eire Dept. Agr.* **36**, 230–45(1939).—The digestibility coeffs. for dry matter, org. matter, crude protein and N-free ext. were practically the same in flaked barley as in barley meal. The coeffs. for ash and fat were of little significance and the coeffs. for crude fiber were unexplainably inconsistent. K. D. Jacob 2

Production of firm pork from peanut-fed pigs. Earl H. Hostetler, J. O. Halverson and F. W. Sherwood. *N. Carolina Agr. Expt. Sta., Tech. Bull.* **61**, 44 pp.(1939).—The degree of firmness of fat in pork can be reliably estd. by the I no. of the back or leaf fat. The m. p. of the back fat is also a reliable index of firmness. Both m. p. and I no. are better correlated with fat grade than n of the fat. The addn. of cottonseed meal to the ration results in an increase in fat firmness in the carcass. There is a high correlation between the degree of firmness of the carcass and the amt. of peanut or other softening oil eaten by the pig. As little as 10 lb. of peanut oil may produce soft pork. Rations high in starch and low in oil produce firm carcasses. Brewers' rice produces firmer carcasses than corn. The highly unsatd. oil in corn exerts an appreciable softening effect. Milo and corn are about equal in hardening effect. Pigs weighing as much as 100 lb. should not be fed peanuts if firm carcasses are desired. There is no particular advantage in adding cottonseed meal to peanuts for the purpose of producing firm carcasses. C. R. F. 3

The nutritive values of Indian cattle foods and the feeding of animals. K. C. Sen. *Imp. Council Agr. Research, Bull.* No. **25**, 39 pp.(1938).—Analyses are recorded of 150 native grasses and other green feeds, 108 hays, 11 legume hays, 30 straws and 41 concentrates. Digestibility coeffs are given for the constituents of 105 feeds and nutritive values are calcd. for 152. E. O. Whittier 4

Drying hay in the barn and testing its feeding value. J. W. Weaver, Jr., and C. E. Wylie. *Tenn. Agr. Expt. Sta., Bull.* **170**, 5–24(1939). In order to operate barn driers economically, about 75% of the water should be removed in the field and the hay then dried to about 20% moisture in the barn drier. The barn-dried hay averaged 2.3% more leaves and 19% more carotene than field-cured hay. Feeding trials indicate a superior feeding quality in the barn-cured hay. Mech. driers are described. C. R. Fellers 5

Nutritional deficiencies in southern livestock production. R. H. Lush. *Proc. Assoc. Southern Agr. Workers* **40**, 75–6(1939). P and Ca deficiencies are rather widespread in Louisiana pastures except those on alluvial or other good land. Grass hay cut from fertilized plots of flatwoods land averaged 0.573% CaO and 0.311% P_2O_5, 6.9% and 29.6% more, resp., than hay cut from unfertilized plots. Spring-cut hays averaged 76% more Ca and 24.4% more P than fall-cut hays. Samples collected from farms where no pasture improvement had been made averaged much less Ca and P. Early pasture hays cut from alluvial lands averaged 0.986% CaO and 0.891% P_2O_5, while summer composites from the same plots averaged 0.576% CaO and 0.764% P_2O_5. When differences in fertility and yield per acre are considered, the best Louisiana pastures are producing more than 5 times as much Ca and 12 times as much P as untreated flat-woods pasture. K. D. Jacob 6

Time and rate of seeding soybeans and effect of time of harvesting on composition and acre yield. S. V. Stacy, O. E. Sell and S. J. Hadden. *Proc. Assoc. Southern Agr. Workers* **40**, 62–3(1939).—Detns. of crude fiber, crude protein, ether-ext. and N-free ext. on 4 varieties of soybean plants cut at various stages of growth in 3 successive yrs., indicated that in yrs. of normal or above normal rainfall the highest yields of feed nutrients are obtained when harvesting is delayed until the beans are well-filled but not ripe and not many leaves have fallen. In dry yrs. leaves are lost in such quantities that harvesting should not be delayed much beyond the full-blossom stage. K. D. J. 7

Eleven years of soybean investigations. W. L. Burlison, C. A. Van Doren and J. C. Hackleman. *Illinois Agr. Expt. Sta., Bull.* **462**, 123–67(1940).—Soybean plants of 16 varieties in the best stage of growth for hay averaged after drying 1/3 each of leaves, stems and pods. During the process of field curing and harvesting 24 varieties for hay, approx. 74% of the oven-dry wt. of the leaves, 77% of the stems and 89% of the pods were saved. Straw yields per acre averaged about 1.15 tons. Moisture content of the crib-dried beans varied from 10 to 15%., being most variable at the surface. Germination was low in seeds which had been subjected to variations in moisture content. Greater acidity was also found in the beans at the surface or upper levels after 3 years' storage. I no., n, oil content, total N, sol. N and carbohydrate content were not affected by depth of storage in the bins. C. R. F. 8

The phytic acid content of some poultry feeding stuffs. R. H. Common. *Analyst* **65**, 79–83(1940); cf. *C. A.* **33**, 4651[1].—The method used for the analysis was essentially that of Young (*C. A.* **30**, 3362[2]). The analysis of about 30 cereals that are likely to be present in the feeding stuff shows that about 3/4 of the P present derived from cereals will be in the form of phytic acid. The phytic acid is probably of significance with respect to the Ca-P metabolism of the fowl. W. T. H. 9

Partition of the less easily digested carbohydrate complex of forages. Russell E. Davis and Charles O. Miller. *Ind. Eng. Chem., Anal. Ed.* **11**, 651–2(1939).—A method is described for the detn. of lignin in grasses and legumes ground to pass through a 0.5-mm. screen and treated with enzymes to remove N. Directions: Ext. a 1-g. sample for 16 hrs. with anhyd. ether, dry and place in a 100-ml., wide-mouth, glass-stoppered bottle and moisten with distd. H_2O. Autoclave 1 hr. at 18 lb. to prevent mold growth. Cool, add 50 ml. 0.1 N HCl and 0.1 g. pepsin (1–3000) and incubate 48 hrs. at 40° with occasional shaking. Neutralize with NaOH and adjust to pH 4.5 with HCl. Add 0.1 g. clarase and incubate 48 hrs. Filter and wash residue with H_2O. Return it to the bottle and add 60 ml. of an aq. ext. of trypsin powder. Make alk. with NaOH and incubate 96 hrs. Filter and wash the residue with H_2O, alc. and ether. Dry at 110° and weigh. Report as undigested residue. Make all filtrations through 200-mesh bolting silk. Transfer the residue to Al moisture dishes for drying and weighing. Hydrolyze the undigested residue with 5% (by wt.) H_2SO_4 for 1 hr., filter and wash residue with hot H_2O and alc. Dry, transfer to a 100-ml. beaker, place in a freezing bath and add slowly 20 ml. of 72% (by wt.) H_2SO_4. Remove from bath after 15 min. and allow the reaction to continue for 45–60 min. at room temp. Stir during the entire reaction period. Transfer to a 1-l. Erlenmeyer flask, dil. to 3% acid by wt. and reflux for 2 hrs. Filter within 30 min. and wash the residue with hot H_2O. Dry at 110°, weigh and reweigh. The loss is lignin. The sum of lignin and cellulose is usually considerably less than the undigested residue obtained by enzymic digestion. Excess formaldehyde used in the Crampton and Maynard method (*C. A.* **32**, 7527[5]) resulted in a quicker soln. of the sample, improved the rate of filtration and increased the yield of lignin. The increase in the apparent lignin content of grass is probably due to the formation of a resin by the action of formaldehyde on some compd. in the grass. F. W. Marsh 10

Pasture studies. XV. The intraseasonal changes in the nutritive value of pasture herbage. E. W. Crampton and R. P. Forshaw. *Sci. Agr.* **19**, 701–11(1939); cf. *C. A.* **33**, 8850[2]; **34**, 2093[1].—The limitations of the standard feeding-stuffs analysis as an indication of the feeding value of pasture herbage as measured by the growth of rabbits are shown. The modified feeding-stuffs analysis of Crampton and Maynard (*C. A.* **32**, 7527[5]) is used in an attempt to explain the observed seasonal changes in nutritive value. A progressive decline in growth-promoting value and digestibility of herbage from spring to midsummer and a complete recovery in both respects in the

fall grown herbage was shown. The nutritive value of herbage may change appreciably in a 10-day period in summer. Both amt. and mode of deposition of the lignin affect digestibility and nutritive value of herbage.
C. R. Fellers

Determination of fat in fish meal. G. B. van Kampen and L. Westenberg. *Verslag. Landb. Onderzoek.* No. **45**, E, 419-25(1939).—As a result of their expts. with several brands of fish meal using a no. of fat solvents, the authors recommend the plain petr. ether extn. instead of the Berntrop method. J. C. Jurrjens

The analysis of the fibrous and carbohydrate constituents of feeding stuffs. I. The furfuraldehyde-yielding constituents. E. G. Hallsworth. *J. Soc. Chem. Ind.* **58**, 357-63(1939).—The rate of evolution and the quantities of furfuraldehyde (I) obtained by digesting various mixts. of plant materials and pentose sugars were studied (cf. Marshall and Norris, *C. A.* **31**, 7941[5]). To ascertain whether the standard distn. procedure insured distn. of all the I, a variety of substances, from xylose to the indigestible residue from cow excreta, was used. I in each fraction was detd. by adding a known excess of bromide-bromate soln. (3 g. $KBrO_3$ and 50 g. KBr per l.) and setting aside for 1 hr. The excess Br not absorbed by I was then detd. by an excess of solid finely divided powd. KI, and detg. the I released by titration with thiosulfate. The iodide was added immediately before detn. to prevent errors from oxidation of the KI by the air. Results showed a distinct difference between the rates of formation of I from xylose and from arabinose. The standard method of collecting 360 cc. distd. at the rate of 30 cc. in 10 min. was found to be considerably in error for arabinose if more than 0.03 g. of the sugar was present. To investigate whether the admixt. of other materials with the pentose sugar adversely affects the recovery of the sugar as I, known amts. of pentose sugar in HCl soln. were added to relatively much greater wts. of plant materials, such as dried grass, pectin, etc., and I-yield of the mixt. was detd. The excess Br-iodometric titration was satisfactory for the detn. of small quantities of I-yielding material even in the presence of relatively large amts. of extraneous org. matter. Factors are suggested for the use of this method with xylose, arabinose and material of uncertain compn. Expts. showed that the factors to convert I to the appropriate sugar are: xylose = I × 1.71; arabinose = I × 1.96. With materials which may contain both arabinose and xylose, to convert I to pentosan the average of the 2 figures should be used, i. e., pentosan = I × 1.835 which will introduce a max. error of 6% if the pentosan consists entirely of either xylan or araban. Fourteen references. **II. The determination of cellulose.** *Ibid.* **59**, 9-17(1940). —The cellulose content of alfalfa meal, bran and decorticated cotton cake was detd. by 7 different methods for comparison purposes. The methods used were those of Simon and Lohrisch (cf. *Z. physiol. Chem.* **42**, 55(1904)), Waksman and Stevens (cf. *C. A.* **24**, 2965), Norman and Jenkins (cf. *C. A.* **28**, 3157), Hoffmeister (cf. *Landw. Jahr.* **17**, 239(1888)), Konig (cf. *Landw. Vers.-Sta.* **65**, 55(1907)), Honig (cf. *Chem. Ztg.* **14**, 868(1890)) and Williams and Olmstead (cf. *C. A.* **29**, 3700[7]). The cellulose obtained by any one method varied widely in compn. with the material from which it is obtained. Thus, although the pentosan was highest in the case of Norman cellulose, it varied from 26.24% in alfalfa to 51.17% in cotton cake. Variation in the compn. obtained by different methods on the same material, however, was much greater. The variation in the amt. and compn. by the different methods supports, according to H., the conclusion that the most satisfactory method to use in animal-feeding studies is that which gives the greatest recovery 1 of nonstarchy hexosan. To det. nonstarchy hexosan, the most satisfactory procedure is as follows: The fiber is first freed as completely as possible from the starch, protein and fat by the enzymic digestion of Williams and Olmstead. On the resulting fiber, the lignin, protein, pentosan and ash must be detd., after which "true cellulose" or more correctly "nonstarchy hexosan" can be detd. by difference. However, very labile nonstarch 2 hexosan may escape detn. by this method. M. M. R.

Seasonal variation in Co content of North Island pastures (McNaught, Paul) **15**. Absorption of nutritive elements by lupines [use of plants as fodder] (Wojtysiak) **11D** Luximeter [for detn. of degree of pasteurization of milk] (Carson) **1**. Apparatus for mixing a current of air with a volatile substance evolved from a liquid as a result of the continual addition thereto of definite quantities of a reagent. Adrianus Kleijn. Brit. 508,773, July 5, 1939. The app., of use for the *bleaching of flour* and *milling products* with halogenated N compds., especially NCl_3, consists of a container, a cover thereon, a partition extending from the cover to a certain distance from the bottom of the container and dividing it into 2 parts which, when liquid is contained therein at the normal level, are completely sepd., an aperture in the cover above 1 of these parts, a 6 charging device for adding the agent to the liquid connected with this part, an air conduit connected with another aperture in the cover of this part of the container, a blower having its suction side connected with the air conduit, a conduit connected with the blowing side of the blower and extending through the cover of the other part of the container to below the normal level of the liquid therein and there provided with distributing apertures, and a discharge air conduit connected with an aperture in 7 the cover of this other part of the container.

Reconstitution of dried egg material. Leon D. Mink (to Industrial Patents Corp.). U. S. 2,183,515, Dec. 12. Dried egg material is mixed with water in the proportion normally found in fresh egg material, and with a "surface-active" agent such as Na stearyl sulfate or Na lauryl sulfate, and the mixt. is whipped. U. S. 2,183,516 relates to drying egg material after the addn. of a "surface-active" 8 agent of like character, such as 0.1-0.3% of Na lauryl, palmityl or stearyl sulfate.

Coloring fruits such as oranges. Kenneth H. Klipstein (to American Cyanamid Co.). U. S. 2,184,237, Dec. 19. The whole fruit is subjected to the coloring action of an aq. soap dispersion of a xylene azo β-naphthol dye contg. less than 30% of the meta isomer (suitably at a temp. of about 38-52°).

Preserving juices of fruits, vegetables, etc. Felix 9 Trzoska. Brit. 508,333, June 29, 1939. See Fr. 836,661 (*C. A.* **33**, 5537[3]).

War gases. Lucien Dautrebande. *Presse méd.* **47**, 1489–90(1939). A. E. Meyer

War gases and other toxic substances. Louis Diserens. *Teintex* **5**, 2 9(1940).—The importance of the following factors in war gases and related materials is reported: stability, d., volatility, height of vaporization, m. p., ease of atomization, soly., action on metals, odor, color and toxicity. A list of some gases is given, classified as asphyxiants, vesicants, respiratory irritants, lachrymators and general poisons. The specific use, phys. and chem. properties, prepn., and physiol. action of the following gases are discussed: Cl_2, $COCl_2$, $ClCOOCH_3$, $ClCOOCH_2Cl$, $ClCOOCHCl_2$, $ClCOOCCl_3$, CCl_3NO_2, $S(CH_2CH_2Cl)_2$, $ClCH.CHAsCl_2$, $(ClCH\ CH)_2AsCl$, $(ClCH\ CH)_3As$. Saverio Zuffanti

Antigas preparations and war-time antiseptics. F. V. Wells. *Soap, Perfumery & Cosmetics* **12**, 830–4, 854 (1939).—A review. M. M. Piskur 6

Use of mercurochrome for mustard gas burns. Anon. *Pharm. Weekblad* **77**, 22 8(1940).—Mercurochrome is not effective in the treatment of mustard gas burns. Felix Saunders

The reaction between 2,2′-dichlorodiethyl sulfide (mustard gas) and bleaching powder. A. G. Lipscomb. *Analyst* **65**, 100(1940).—The reaction between mustard gas and bleaching powder is violently exothermic and the mixt. often takes fire. Sometimes, however, a given sample will inflame with one sample of bleaching powder and will not with another. Thus a sample of specially good bleaching powder from a freshly opened tin gave no sign of reaction with mustard gas. When a few drops of water was added, however, the whole mass burst into flame. This would seem to indicate that lack of reactivity between mustard gas and bleaching powder may be caused by the dryness of the latter. W. T. H. 7

The fundamental properties of poisonous substances when applied to water supply. E. A. Dianov. *Vodosnabzhenie Sanit. Tekh.* **1939**, No. 2, 32–6; *Khim. Referat. Zhur.* **2**, No. 5, 96(1939).—Open water reservoirs are most vulnerable to contamination by poisonous substances from airplanes. The usual contaminants are stable poisons (yperite, lewisite). The properties of poisonous substances, their behavior in water and methods for decontaminating the poisoned water are described briefly. Methods for detection of poisons are given. The water reservoirs can also be poisoned by strophanthin, capsaicin, etc. Data on the penetration depth of the poisons into building materials are also given. W. R. Heun 9

Methods of recovery of volatile solvents and its importance in national economy. A. P. Okatov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 424–30(1939).—A discussion of the Soviet and foreign practices. Twenty-five references. Chas. Blanc

Chemistry and toxicology of [vapors of] solvents. F. Flury. *Chem. Fabrik* **12**, 3 6(1939).—Narcotic action, which is often related to the phys. properties of the solvent, is not parallel with toxicity, which depends rather on chem reactivity. Such specific poisons may be classified according to the organs which they mainly attack. The risk of injury depends partly on the volatility of the solvent. B. C. P. A.

Water spray as a means of fighting respiratory poisons. Möbius. *Feuerschutz* **20**, 2–4(1940).—A spray of water made with a nozzle can be used to decrease the hazard to life from industrially used toxic gases that have escaped from their containers (Cl, NH_3, SO_2, HCl, H_2S, etc.) and to counteract the effects from war gases. The efficiency of this "atomized" water depends on the soly. of the chemicals, adsorption, increased reactivity, etc. The application of the method is described. Leopold Scheflan

A unified presentation of results from grain size and falling-velocity determinations in dust studies. Torsten Widell. *Iva* **1939**, 163–70.—Mostly math. W. J. Peterson

Antimony in professional pathology. André Feil. *Presse méd.* **47**, 1133–4(1939).—The symptoms of industrial poisoning with Sb are described. A. E. Meyer

Occupational arsenic poisoning and its detection by chemical methods. F. Kunkele. *Chem.-Ztg.* **64**, 29–32, 37–8(1940).—The chief causes of occupational As poisoning are reviewed and the colorimetric method for the detn. of As in the human body is described. The effects of occupational (chronic) As poisoning are discussed on the basis of clin. cases both of agricultural (vineyard) and industrial workers. Arsenic contents higher than 10 γ per 100 cc. of urine and 3 γ per g. of the hair of the head indicate As poisoning. Pubic hair may contain 3–8 times as much As as hair of the head. As much as 150 γ per 100 cc. of urine and 120 γ per g. of hair of the head have been observed. A. H. Krappe 5

Further studies on the absorption, mobilization and excretion of lead. S. L. Tompsett. *Brit. J. Exptl. Path.* **20**, 512–16(1939); cf. *C. A.* **34**, 1055³.—The addn. of HCl to the diet increases the absorption of Pb from the alimentary tract. NH_4Cl, $NaHCO_3$ and KI produce mobilization of Pb on both a low and a high Ca intake. Recently absorbed Pb may be excreted very rapidly after removal from exposure. In all the expts. in which mice were used, the administration of relatively large amts. of Pb appeared to have little effect upon the general bodily health of the animals. Harriet F. Holmes

A.* **33**, 8854².—The inferior qualities (discoloration, swelling and permeability to water) of pressed articles from soybean casein and resinol were traced to the presence of decompn.

products of albumins. The phys. and mech. properties of the moldings can be greatly improved by the use of casein or press cake freed from the decompn. products by preliminary washing with dil. NaOH and neutralizing with 4% HCl. Chas. Blanc

Cellulose acetate plastics. B. Righi. *Atti X° congr. intern. chim.* **4**, 186–9(1939).—A historical outline of the development of cellulose acetate, with brief mention of all recent improvements, leading to the production of a substitute for glass, and to other applications. A. H. Krappe

Behavior of polyvinyl chloride plastics under stress. J. J. Russell. *Ind. Eng. Chem.* **32**, 509–12(1940).—Tensile stress-strain diagrams at −50° to 80° are given for various polyvinyl chloride plastics contg. 40% plasticizer. The stress-strain curves change in shape as the temp. is lowered, ultimately reducing to a "brittle point" characteristic of the compn. Heats of activation for these plastics are 4.8–6.2 kg.-cal., similar to those of pure metals; Poisson's ratio is about 0.5 A. F. Shepard

Esters of cativic acid. Nicholas L. Kalman. *Paint Manuf.* **10**, 33(1940).—Cativic acid has the formula $C_{20}H_{34}O_2$ and is a monobasic acid obtained from the exudate of the semitropical tree *Prioria copaifera*, Griseb. The formula closely resembles the formula of abietic acid. Constitutional dissimilarity is evidenced by the fact that cativic acid esterifies with great ease and, it and its derivs., are very stable to ultraviolet light. Suitably treated, cativic acid decarboxylates easily, forming a hydrocarbon "cativene" which boils at about 160° at 3 mm. The esters of cativic acid are practically tasteless, colorless and odorless and are sol. in all the ordinary org. solvents, but not in water The esters may be used as *plasticizers*, as modifiers in conjunction with various resins with which they may be compatible, with adhesive compns. of several kinds and as agents to improve water resistance of many materials. Cativic acid or certain of its esters may be used as an agent for modifying, plasticizing or otherwise affecting the properties of various synthetic resins. Al cativate forms a clean, transparent film which is brittle and relatively inflexible. By the use of suitable esters of cativic acid the film may be plasticized as desired. W. H Boynton

Properties of products obtained from mixtures of natural and synthetic high-molecular compounds. Z A. Rogovin and L. A. Zaplina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 455–6(1939).—A preliminary communication. The addn. of 5–20% Novolac to 10% cellulose acetate in Me_2CO resulted in 35–50% increase of the mech. strength of films dried at 65–140° for 5 hrs The elasticity, elongation and hygroscopicity decreased. The intense coloring of the films limits their use in com. practice. Chas. Blanc

Relation between the degree of fineness of molding powders and the mechanical strength of the resulting pressed articles. M. I. Gurter and E. N. Freidberg. *Org. Chem. Ind.* (U. S. S. R.) **6**, 456–7(1939).—Comparative tests showed that the mech. and phys. properties of pressed articles considerably improve with greater fineness and uniformity of powd. molding compds. For com. use sifting to 35 mesh/sq. cm. is recommended. C. B.

Colored molding materials. E. M. Efimova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 498 500(1939); cf. *C. A.* **34**, 2096⁷.—Some addnl. expt. data are given. C. B.

Phenol-formaldehyde resins. VII. A note on viscosity and density of solutions in organic solvents. O. Sugita and S. Turuta. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 327–8(1939); cf. *C. A.* **33**, 3021².—Based on solns. (25 g./100 cc. of solvent) of resin, prepd. from 1 mol. PhOH, 1 mol. CH_2O and NH_3, in solvents such as MeOH, EtOH, PrOH, Me_2CO, McCOEt, MeOAc, AcOH, C_5H_5N or $ClCH_2.CH_2OH$, no relation exists between the relative viscosities of solns. and abs. viscosities of solvents. AcOH and C_5H_5N gave solns. having higher viscosity for the same resin concn. than did the other solvents. The formula, $\log \eta_r = KC^a$, applies to AcOH and Me_2CO solns. of resin at 25°, where η_r = relative viscosity of the soln., $K = 244 \times 10^{-4}$ (AcOH) or 116.5×10^{-4} (Me_2CO), C = g. resin per 100 cc. of soln., and a = 1 (AcOH) or 1.18 (Me_2CO). A straight-line relation exists between concn. and d. of resin solns., whereby $d = d_o + mc$, and $m = [1 - (d_o/d_s)]/100$, d_o = d. of solvent, d = d. of soln., c = concn., and d_s = d. of the solute. Values of d_o, d_s and $m \times 10^5$ for resin solns. in the solvents mentioned are (25°): AcOH, 1.053, 1.26, 167; PhOH-formalin-EtOH mixt. (1:1:0.5 mol.), 1.015, 1.22, 170; C_5H_5N, 0.9810, 1.17, 216; Me_2CO, 0.7826, 1.30, 397; 0.5 *N* NaOH, 1.019, 1.17, 132; 1 *N* NaOH, 1.039, 1.17, 115; 1.5 *N* NaOH, 1.060, 1.18, 101; 2 *N* NaOH, 1.079, 1.20, 88. George Ayers

Kinetics of the formation of phenol-aldehyde resins. Z. V. Veldenbaum and E. S. Medvedkov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 437–41(1939).—In the preliminary communication the proposed methods of lab. control in the condensation of PhOH and CH_2O are critically discussed. More satisfactory results were obtained by vacuum distn. with steam of the reaction mixt., dissolving the residue in alc. to give a 20% soln. of resin and detg. the degree of polymerization from its viscosity. C Blanc

Phenol-formaldehyde rods and tubes for electrical purposes. E. E. Halls. *Plastics* (Brit.) **4**, 13–14(1940). Heat loss and H_2O-absorption values are given for various grades and sizes. A. S. Shepard

The composition and formation of technical coumarone resins. Richard S. Hilpert and Seigfried Osborg. *Brennstoff-Chem.* **20**, 81–3(1939).—Resins obtained in H_2SO_4 treatment of crude benzene from the Ruhr and Upper Silesian districts were examd. in a comparative study of coumarone and indene resins and their reaction products. The O contents varied from 2 to 3% in comparison with 13% for the polymerized coumarone and were unrelated to color and consistency. One was nearly pure hydrocarbon. Hygroscopic compds. contg. 3.76, 2.30 and 1.58% S were obtained by treating a coumarone resin distg. 171–72° (picrate m. 101–2°) with 90, 80 and 70% H_2SO_4 in the cold, several days being required with the last concn. to obtain the solid mass from the suspension. Not quite all of the acid was removable in the regeneration of the resin with H_2O treatment of the acid products. Acid treatment of indene, b. 181° (picrate m. 97–98.5°), was accompanied by SO_2 liberation; products contg. 1.18 and 0.23% S were obtained readily with 90 and 80% acid and were similar in compn. and m. p. (79–84°) to tech. resins. Distns. of coumarone resins from a metal bath at 300°, repeated until distillates were colorless, gave material which reacted only slowly with concd. H_2SO_4. Color reactions with H_2SO_4 in Ac_2O of a no. of related resins show the predominance of the red-violet coloration. F. W. Jung

Synthetic materials as mill bearings. Successful application to steelworks practice. C. D. Phillipe. *Iron & Coal Trades Rev.* **139**, 797–8(1939).—The manuf. and constitution of thermoplastic and thermo-hardening plastics of the phenol-formaldehyde resin group is discussed and their main properties, advantages and disadvantages in rolling-mill and other steel-mill applications are described. I. Hartmann

Hydrocolloidal [dental] impression materials: physical properties and a specification. George C. Paffenbarger. *J. Am. Dental Assoc.* **27**, 373–88(1940).—The essential and important ingredient usually is agar-agar. Detailed specifications are proposed. Joseph S. Hepburn

Soybean-protein dispersions in formaldehyde solutions. Preparation and application. Allan K. Smith and Herbert J. Max. *Ind. Eng. Chem.* **32**, 411–15(1940).—Dispersions of soybean protein in concns. as high as 10% were prepd. in the presence of 2–10% CH_2O. The dispersions were most stable at the neutral point but can be prepd. with pH values as low as 5.7. Salts, such as borax and Na_3PO_4, and low temp. delayed gelation. Higher concns. of the protein-CH_2O dispersions were made possible by a mild hydrolysis with dil. alkali or by the action of souring bacteria or yeast on the water dispersion of the protein. Com. applications were found in the fields of *surface-sizing glassine paper, laminated plastics* and *leather dressing.* David B. Sabine

Manufacture of uniform casein. W. E. Stringer. *Paper Trade J.* **110**, No. 11, 46–8(1940).—A description of progress made in the manuf. of casein, showing how the elimination of various technical and mech. difficulties has resulted in a continuous process of casein manuf. 1
A. Papineau-Couture

Glass as an electrical insulator. C. J. Phillips. *J. Applied Phys.* **11**, 173-81(1940).—A review of the phys. properties of different types of glasses, including those of fiberglass. 2
S. L. Gerhard

Experimental investigation of Australian-made dielectrics. Arthur W. Martin. *Trans. Inst. Engrs., Australia* **20**, 411–16(1939).—A detailed study of the mechanism of dielec. failure of bakelized paper bushings and bakelized canvas bushings. It was found that the capacity of a given sample and hence its dielec. const. increase with temp. at const. frequency. The loss angle and power factor of the material increase with temp. at const. frequency. At const. temp. the dielec. const. and loss angle decrease with increasing frequency over the range 100 to 10,000 cycles and between the temp. 15° and 40°. 3
C. G. F.

Paste for cellophane. I. R. Morozov and G. P Petrov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 462–3(1939).—Analysis of an imported paste for cellophane showed that it contains erythrodextrin + glycerol 36, PrOH 15, H_2O 47 and ash 2%. An equally good product was obtained from 33 g. dextrin in 45 ml. H_2O contg. 15 ml. alc. and 5 g. glycerol. The filtrate is decolorized with 2 ml. of 2% $Ca(OH)_2$. 4
Chas. Blanc

Glue-top on zinc. Addison G. Brooks. *Process Engraver's Monthly* **46**, 221, 223(1939).—The use of the conventional "ink-top" etching resist, i. e., albumin reinforced with etching ink, has been improved by the addn. of glue to the albumin and the properties of the resist can be still further improved by leaving out albumin entirely. The resulting "glue-ink-top" or "glue-cold-top" keeps longer in soln., prints a little faster, develops more easily, has a fine etching resist and is less affected by atm. conditions. A 1% soln. of CrO_3 is recommended to increase the HNO_3 resistance of the glue, but care must be taken not to overharden. 5
R. F. W. Selman

The stability of emulsions. I. Soap-stabilized emulsions. A. King and L. N. Mukherjee. *J. Soc. Chem. Ind.* **58**, 243–9(1939).—By means of the size-frequency technique the total area of interface per g. of emulsified oil has been detd. for kerosene-water and olive oil-water emulsions stabilized by various soaps. The rate of change of interfacial area is the best measure of unstability of an emulsion. Na and K soaps are better emulsifying agents than NH_3 soaps; the fatty acids in order of increasing efficiency are palmitic, stearic, and oleic. The mech. method of emulsification influences both degree of dispersion and stability. $CaCl_2$, HCl and heat increase globule size and decrease the stability. 6
R. E. R.

(Testing methods for) emulsion floor waxes. Melvin Fuld. *Soap (Sanitary Products Sect.)* **16**, No. 1, 111, 113, 123(1940); cf. *C. A.* **33**, 7430⁹.—A uniform film for testing purposes was obtained by use of a highly polished metal roller which was undercut from its shoulders 0.001″ The wax should be reduced to approx. 10–12% nonvolatile solids for the test. Tests for detg. nonvolatile solids must be run very carefully by essentially the method described in Federal Specification PW-151. A desiccated balance must be used. Other aspects of the method are described. 7
Henry H. Richardson

Shear markings in asbestos fibers. A. Frey-Wyssling. *Z. wiss. Mikroskop.* **56**, 309–16(1939).—"Nodes" analogous to those in some cellulose fibers, are formed by working, with an opening-up of the structure, yielding microscopic fibrillae and lower strength. 8
C. W. Mason

Basebond Litho Sheet. A. V. Mackenzie. *Process Engraver's Monthly* **46**, 231(1939).—A new type of lithographic printing plate, the Basebond Litho Sheet (developed in Canada), uses a sheet steel base on which Zn and a relatively small amt. of Al are deposited electrolytically. It is claimed to be less susceptible to oxidation and to be stronger than Zn or Al. 9
R. F. W. Selman

The use of boron carbide in the cutting of semiprecious stones. W. Dawihl and O. Fritsch. *Schlief- u. Poliertech.*, **15**, 175–6(1938); *Chem. Zentr.* **1938, II**, 3441–2.—Grinding and polishing tests showed B_4C to be about 70% as effective as diamond powder in the cutting of semiprecious stones (rubies). It can be used as a substitute for diamond in these operations. Further tests led to the conclusion that the greater attack of the abrasive on multicryst. Al_2O_3 is conditioned by the attack along the boundaries of the grains. 10
W. A. Mobre

Lithographing the tin can. George E. Monroe, Jr. *Products Finishing* **4**, No. 6, 9–10, 12(1940).—A description of chem. and mech. treatments at the American Can Company's Englewood plant in Chicago. 11
L. S.

Use of protective films of insecticide in control of indoor insects, especially Plodia interpunctella and Ephestia elutella. C. Potter. *Ann. Applied Biol.* **25**, 836–54 (1938).—Provided stored goods are sterilized, spraying the interior of warehouses and the packing cases repeatedly with a soln. of 0.8% of pyrethrins in white oil gives protection against infestation. The oil has little part in the toxic action, β′-Thiocyano-β-butoxydiethyl ether, used similarly, gave promising results. 12
B. C. P. A.

Comparison of mosquito repellency tests under laboratory and field conditions. Philip Granett. *New Jersey Mosquito Extermination Assoc., Proc. Ann. Meeting* **25**, 51–7(1938).—Caged mosquitoes (*Aedes aegypti*) were shown to be more easily repelled by various chemicals (not specified) than were field (salt-marsh) mosquitoes principally *A. sollicitans* and *A. cantator*. The better repellents were approx. 70% as effective outdoors as in the cage, whereas the poorer repellents (those repellent for less than 0.5 hr.) were only about 25% as effective. 13
K. D. Jacob

Progress in mosquito control in Delaware County, Pennsylvania. R. L. Mentzer. *New Jersey Mosquito Extermination Assoc., Proc. Ann. Meeting* **26**, 148–51 (1939).—Addn. of 10 drops of a stock soln. of *pyrethrum larvicide* to the water consumed by a cow in 24 hrs. produced no unusual taste in the milk. The cow refused to drink water that contained larger quantities of the larvicide. 14
K. D. Jacob

Mosquito-suppression work in Canada in 1937. Arthur Gibson. *New Jersey Mosquito Extermination Assoc., Proc. Ann. Meeting* **25**, 176–85(1938); cf *C. A.* **32**, 1354⁴.—In practical expts. under different conditions a mixt. of equal parts of olive oil and pyrethrum ext. (Penick's Pyrefume Super 30) gave effective protection against blackflies and mosquitoes for periods of 1.5–4.0 hrs. In tests on carriers of pyrethrum ext., castor oil was the most lasting, followed in order by glycerol, olive oil and petrolatum. Various forms of essences of thyme and geranium had definite promise as repellents. Cinnamaldehyde and cresol were comparatively effective but were too severe on the skin. Phenyl salicylate, bay laurel, pine oil, clove and citronella had definite repellent properties. Citral, oil of cedar, bitter orange and geranyl acetate gave protection over somewhat shorter periods of time. The distn. fractions of oil of tar appeared to be fairly efficient repellents, without possessing the undesirable properties of the original material. **Mosquito-suppression work in Canada in 1938.** *Ibid.* **26**, 109–16(1939).—A mixt. of oil of thyme 0.5, concd. ext. of pyrethrum in mineral oil (Penick's Pyrefume Super 30) 1 and castor oil 2–3 fluidoz. gave protection against mosquitoes for 3–5 hrs. Ext. of pyrethrum incorporated in ointments composed of various combinations of paraffin, lanolin, tallow and beeswax was an effective repellent, but the ointments were not so satisfactory as liquid prepns. contg. pyrethrum and they were somewhat oppressive and irritating to the skin. Promising results were obtained with a mixt. of coconut oil 6, pennyroyal oil 1, oil of lavender 1 and spirits of camphor 0.5 part. 15
K. D. Jacob

Automatic destruction of mosquitoes in airplanes and the vector of yellow fever in aerial travel in Africa. G. A. P. Ross. *Bull. office intern. hyg. publ.* **30**, 2002–31 (1938); *Rev. Applied Entomol.* **27B**, 48–9.—Tests showed that an aq.-base ext. of pyrethrum at a dilu. of 1:14 was as

inflammable as an ext. of pyrethrum in CCl_4 (1:4) but both are noninflammable from a practical point of view. A 1:5 CCl_4 diln. gives ample margin of safety from fire. A small pressure sprayer placed in each compartment of a hydroplane distributed its charge of insecticide in a few min. and dosages per compartment of 30 cc. of the 1 5 CCl_4-base ext. and 50 cc. of a 1.10 aq.-base ext. killed all the mosquitoes in 10 and 16–18 min., resp. The mosquitoes used were *Anopheles gambiae* Giles.
Edwin J. Seiferle

The action of insecticidal powders on anopheline larvae in relation to the degree of dispersion of the poison and the concentration of added substances. N. K. Shiputsma. *Med. Parasitol.* (U. S. S. R.) **7**, 346–71(1938) (in Russian); *Rev. Applied Entomol.* **27B**, 68. —Expts. were carried out in the lab. at 25° with larvae of *Anopheles maculipennis* Mg., race *messae* Flni. taken near Moscow. The larvicides tested were Paris green (I) contg. 50% As_2O_3, and a Cu arsenite prepn., Arsmal (II), with Acidol and contg. 8.6% As_2O_3 and 7.3% CuO. They were applied alone or mixed with talc in the proportion of 1 10 or 1 100, the rates of application being 7 oz. of the undild larvicide and 4.7 and 43.2 lb. of the mixts., resp., per acre. The periods for 50% mortality for first instar larvae were, resp., 50 min., 60 min. and 3.5 hrs. for I and 32 min., 36 min. and 19 hrs. for II; on fourth instar larvae the corresponding periods were 70 min., 80 min. and 2.75 hrs. for I and 80 min., 140 min. and 24 hrs. for II. Edwin J. Seiferle

Employment of the distillate of coke filters for the destruction of the larvae of Anopheles maculipennis. Preliminary communication S. F. Afanas'ev. *Med. Parasit. & Parasitic Diseases* (U. S. S. R.) **7**, 694–700(1938). *U. S. Pub. Health Eng. Abstracts* **20**, Ma, 6(Feb., 1940). —The author employed the distillate of coke filters obtained in the final stages of fractional distn. of Russian petroleum The distillate is composed of heavy oils, including solar oil, and represents a mixt. of hydrocarbons, mainly aromatic compds. In a lab. expt. the distillate was sprayed over the surface of the water in a vessel contg. 60 larvae of *A. maculipennis*. All were killed within 60 min. When applied to natural reservoirs contg. mosquito larvae the distillate caused the destruction of all the larvae and other aquatic animals except Crustacea and *Gambusia*, in 24 hrs. Conclusion: The distillate provides a satisfactory substitute for petroleum and can be used for oiling in the same doses, i. e., about 25–50 g. per sq. m., according to the amt. of vegetation present. C. R. Fellers

Report for 1936 and 1937 of the Malaria Commission of the Health Council of Holland. W. A. P. Schuffner and N. H. Swellengrebel. *Verslag. Mededeel, Volksgezondh.* July, **1938**, 26 pp.; *Rev. Applied Entomol.* **27B**, 51–2 (1939).—Houses were sprayed against *Anopheles maculipennis* Mg., race *atroparvus* van Thiel, with Shelltox, a pyrethrum-kerosene insecticide, at 14–17 fl. oz./house. All the mosquitoes were killed and the houses remained less liable to reinfestation for a fortnight Larvae of the above anophelines were found to be 12 times as numerous in water with a Cl content of 1500 mg./l. as in water with a content under 500 mg./l. Edwin J. Seiferle

The disinfecting action of calcium cyanamide against the housefly shown experimentally. R. Grandori. *Boll. zool. agrar. bachicoltura* **8**, 233–50(1938); *Rev. Applied Entomol.* **27B**, 84(1939). —Eggs and larvae of blowflies reared on putrefying meat were killed by solns. of $CaCN_2$ sprayed on the meat or by a dust of equal parts of $CaCN_2$ and wood ash. A series of expts. on cowshed manure contg. many fly larvae showed that manure can be practically disinfected by $CaCN_2$, the best method being application of a dust of equal parts of $CaCN_2$ and an inert carrier to successive layers of manure 6–8 in. thick and soaking with H_2O. The amt. of $CaCN_2$ applied should be 1 to 1.5% of the wt. of the manure. Adult flies in lab. expts. were killed by feeding on figs wetted with a 5% soln. of $CaCN_2$; a 10% soln. was repellent. Complete mortality was also given by a bait contg. 1 part molasses and 9 parts water, and 1, 2 or 3% $CaCN_2$. Edwin J. Seiferle

Can Paris green kill fish? Sen Purneddu. *Bengal Pub. Health J.* **1**, No. 1, 9–12(June, 1939); *U. S. Pub. Health Eng. Abstracts* **20**, Ma, 4(Feb., 1940).—Extensive experience and observation show that Paris green in the amts. used for mosquito control, does not kill fish or birds. The As contents of fish from treated areas are no higher than from untreated areas. C. R. Fellers

The problem of wallpaper staining by insecticides and insecticide bases. Werner R. Husen. *Pests* **8**, No. 1, 14–16(1940).—Highly refined petroleum distillates (*A*) such as are used as bases for household sprays, and various insecticides dissolved in *A* will stain wallpaper. The more moist the wallpaper the more pronounced the stain. Recently laid wallpaper is thus more susceptible to staining. Stain intensity is highest in starch-sizing wallpapers, less in protein type and rotogravure type papers.
Henry H. Richardson

Insect-control work in Canada. Arthur Gibson. *Pests* **8**, No. 1, 12–13(1940).—Invasion of houses by clover mites is controlled by spraying a kerosene ext. of *pyrethrum*. Carpenter ants are effectively controlled by the use of *derris powder* (4% rotenone). H. H. Richardson

Prolonging toxicity of pyrethrum insect sprays. R. B. Trusler. *Soap (Sanit. Products Sect.)* **16**, No. 1, 115, 117, 119(1940). —To a prepn. contg. 0.2% pyrethrins in a highly refined petroleum base various compds. were added; the mixt. was stored for 3 yrs. at 32° and then tested on houseflies by the Peet-Grady method (*C. A.* **31**, 2315[1]). Benzaldehyde, 0.2%, appeared to prolong toxicity Results with eugenol and β-naphthol confirmed previous work. Other effective antioxidants may be found in aromatic aldehydes. Low-titer oleic acid and a nonvolatile olefin seemed to prolong toxicity. A 70° storage temp. used to increase speed of results seemed too high. A new series testing herbaceous insecticides at 50° storage temp. is being made. Three references. H. H. R.

Plasticizer for mixed cellulose ethers. I. A. Arbuzov and E. N. Rostovskiĭ. Russ. 50,992, April 30, 1937. Addn. to Russ, 48,303. A terpene hydrochloride, e. g., dipentene hydrochloride is heated with a phenol, e. g., cresol to form a plasticizer.

Molding plastic materials under heat and pressure, as in forming gears, from a urea-aldehyde resinoid. Victor H. Turkington (to Bakelite Corp.). U. S. 2,183,857, Dec. 19. App. is described, and a method of molding plastic materials under heat and pressure which comprises forming a material which can be rendered plastic by heat and then hardened, incorporating with the material an added ingredient which expands at the temp. at which the material becomes plastic to produce pores in the plastic material, molding the mixt. under such heat and pressure as to expand the added ingredient while the mixt. is plastic to produce pores and surrounding the plastic mixt. while being molded with a medium capable of minimizing the dissipation of the ingredient from the material, and hardening the material.

Shaping vinylidene chloride polymers. Ralph M. Wiley (to Dow Chemical Co.). U. S. 2,183,602, Dec. 19. In forming products such as films or various molded articles, a material formed at least in large proportion of polymeric vinylidene chloride is heated to a temp. between its softening point and its decompn. temp., rapidly chilled to effect supercooling, and then subjected to shaping, as by rolling or extrusion.

Compositions for making products by molding or extrusion. Henry S. Colton (to H. Seymour Colton, M. J. Rentschler and James A. Weeks, as Trustees). U. S. 2,181,271, Dec. 26. A joint ppt. of $CaSO_4$ and Fe hydroxide and another insol. hydroxide such as that of Al or Mg is used, the wt. of the sulfate being about 1.5 times that of the hydroxides. Cf. *C. A.* **33**, 8331[6].

Soluble artificial resins. Max Kaufmann. Dutch 47,206, Nov. 16, 1939. Resins useful for lacquer manuf. are made by treating condensation products of phenol and formaldehyde at temps. below 150° with polybasic org. acids, avoiding esterification, then esterifying the strongly acid resins with polyhydric alcs. Care is taken to maintain conditions such that only sol. resins are formed.

Olefin-sulfur dioxide resins. Frederick E. Frey and Robert D. Snow (to Phillips Petroleum Co.). U. S. 2,181,295, Dec. 26. An arrangement of app. is described, and a continuous process of producing heteropolymeric resin products which involves charging to a reaction zone olefinic material such as butene, pentene or hexene and SO_2 in liquid phase in such proportions, together with a catalyst, that a soln. of resin product will sep. from the reactants, the soln. being continuously withdrawn from the reaction zone for vaporization of volatile materials from it.

Resinous derivatives from hydroformed naphthas. Wm. J. Sweeney and Kenneth C. Laughlin (to Standard Oil Development Co.). U. S. 2,184,325, Dec. 26. A resinous product is prepd. by a process which involves bringing a naphtha fraction b. about 50–260° and having an aniline point below about −8°, and prepd. by destructive hydrogenation of a SO_2 ext. of a petroleum distillate with a limited proportion of H under conditions suitable for forming antiknock motor fuels, into reaction with ethylene dichloride by boiling the mixt. under reflux in the presence of $AlCl_3$ until the viscosity of the mixt. increases substantially, diluting the mixt. with alc., decomposing the $AlCl_3$ complex with steam, washing the remaining ethylene dichloride soln. with water, and removing solvent and untreated material from the washed soln. by distn. under vacuum.

Decolorizing coumarone-indene resin recovered from still residues. Samuel G. Burroughs (to Pennsylvania Industrial Chemical Corp.). U. S. 2,183,830, Dec. 19. A method of reducing the color intensity of a coumarone-indene resin recovered from a still residue resultant from fractionation and purification of light oil derived in the by-product coking of coal, involves treating the resin in soln. in a solvent, such as solvent naphtha and in the presence of water, simultaneously with a weak acid such as oxalic acid and a finely divided metal such as Zn, while heating to a temp. of about 135°.

Polyvinyl acetal resin sheets. Henry B. Smith (to Eastman Kodak Co.). U. S. 2,184,155, Dec. 19. A transparent, rubbery sheet suitable for use in laminating glass or for a photographic film base is formed with a predominating proportion of a polyvinyl acetal resin the acetal groups of which are largely butyraldehyde acetal groups, together with a sufficient proportion of tetrahydrofurfuryl maleate to give the sheet a rubbery character without substantially impairing its transparency. Cf. *C. A.* **34**, 2101[3,5] and following 4 abstracts.

Polyvinyl acetal resin sheets. Bruce E. Gramkee (to Eastman Kodak Co.). U. S. 2,184,423, Dec. 26. Polyvinyl acetal resin is used with sufficient tributyrin to impart a rubbery character to sheets without substantially impairing their transparency.

Polyvinyl acetal resin sheets. Neil S. Kocher and Henry B. Smith (to Eastman Kodak Co.). U. S. 2,184,426, Dec. 26. A transparent, rubbery sheet comprises a polyvinyl acetal resin in which a predominating proportion of the acetal groups are formaldehyde acetal or butyraldehyde acetal groups and an amount of an alkyl phthalyl ethyl glycolate, in which the alkyl group contains less than 3 C atoms, sufficient to impart to the sheet a rubbery character without substantially impairing its transparency. Such sheets are suitable for *photographic films*.

Transparent, rubbery sheets of polyvinyl acetal resin. Henry B. Smith (to Eastman Kodak Co.). U. S. 2,184,442, Dec. 26. A polyvinyl acetal resin in which a predominating proportion of the acetal groups are acetaldehyde acetal or butyraldehyde acetal groups or both is used with an amt. of triamyl phosphate sufficient to give sheets (suitable for *photographic films* or *laminated glass manuf.*) of a rubbery character without substantially impairing their transparency. U. S. 2,184,443 relates to the like use of triethylene glycol diacetate with a polyvinyl formaldehyde acetal resin. U. S. 2,184,445 relates to a like use of tetrahydrofurfuryl succinate with a polyvinyl acetal resin in which a predominating proportion of the acetal groups are formaldehyde acetal or acetaldehyde acetal groups or both.

Transparent, rubbery sheets of polyvinyl acetal resin. Henry B. Smith and Donald R. Swan (to Eastman Kodak Co.). U. S. 2,184,444, Dec. 26. Triethyl citrate is used as an elastizer with a polyvinyl acetal resin in which a predominating proportion of the acetal groups are butyraldehyde acetal groups.

Condensation products from urea and formaldehyde. Lucien Segond and Paul Michaut. Ger. 684,944, Dec. 8, 1939 (Cl. 12*o*. 17.05). The condensation is carried out in the presence of sulfamides and of Zn.

Insulator. Bruno Neuhof. Ger. 650,652, Jan. 20, 1940 (Cl. 80*b*. 9.02). Mineral wool pulp is treated with materials such as sulfite or sulfate cellulose waste liquors or resin soaps, and also bitumen emulsions and the mass is worked up in the hollander and shaped upon sieves into plates, cardboards, etc.

Electric insulator. Steatit-Magnesia Akt.-Ges. Ger. 684,932, Dec. 8, 1939 (Cl. 21*c*. 2.01). See U. S. 2,165,819 (*C. A.* **33**, 8332[2]).

Laminated heat and sound insulating material. George R. Cunnington (to Woodall Industries Inc.). U. S. 2,184,139, Dec. 19. A supporting layer such as sheet metal is used with a layer of asphaltic mastic and an interposed layer of cellulosic material such as crepe wadding pervious to the flow of fused asphalt, the layer of asphaltic mastic being adhered to the supporting layer by asphalt spewed from the mastic layer through the interposed layer of cellulosic material. U. S. 2,184,140 also relates to manufg. and structural details of laminated insulating material.

Electrical insulation. Edward C. Homan (to Irvington Varnish & Insulator Co.). U. S. 2,183,811, Dec. 19. Bus-bar insulation is made comprising an enveloping sheet of fabric coated with waterproofing material and faced on

its external side with an adhered layer of flexible thermoplastic elec. insulating compn. of high fire and water proof characteristics comprising copolymerized vinyl chloride and vinyl acetate 40, tritolyl phosphate 26, chlorinated diphenyl 13, filler material 19 and Pb oxide as a stabilizing agent 2%, these ingredients in such proportions being adapted to become adhesively tacky under applied pressure and above 120° but which will remain set and nondripping under bus-bar operating temp., the sheet having overlapped meeting marginal portions bonded together by such compn.

Bodies of fibrous glass suitable for use in heat insulation, etc. Donald C. Simpson (to Owens-Corning Fiberglas Corp.). U. S. 2,184,320, Dec. 26. A fabricated body of fibrous glass composed in part of an alkali ingredient is treated, throughout, with a strong inorg. acid capable of neutralizing free alkali on the surface of the glass fibers.

Binding glass fibers in loose formation as for use in heat or sound insulation. Jesse H. Plummer (to Owens-Corning Fiberglas Corp.). U. S. 2,184,316, Dec. 26. Use is made of clay, bentonite, Al powder, or diatomaceous earth as a stiffening material, together with a solid bituminous material such as a tar or asphalt capable of pyrolytic reaction, and the mass is heated to a temp. below the ignition temp. of the bituminous material to cause a breakdown and resinification of the latter with production of a hard tough product.

Apparatus for breaking and splitting up insulating material such as rock wool. Richard B. Patterson (to Patterson Mfg. Co.). U. S. 2,183,583, Dec. 19. Various structural, mech. and operative details.

Vibration absorbing material, suitable for deadening sound. Harry M. Austin and James A. Muir (to Crown Cork & Seal Co.). U. S. 2,184,182, Dec. 26. A vibration absorbing material includes a resilient lamina comprising a mass of rubber-like material having cork particles of greater resiliency than the mass interspersed therein, the resilient lamina having at least one aperture therethrough extending substantially at right angles to the plane thereof, and a relatively stiff lamina directly secured to the resilient lamina and substantially coextensive therewith, the stiff lamina comprising a synthetic resinous sound-deadening material and being sufficiently rigid to distribute load throughout the resilient lamina.

Adhesives containing amylaceous substances such as starch. Hans F. Bauer (to Stein, Hall Mfg. Co.). U. S. 2,183,736, Dec. 19. A remoistening adhesive compn. is formed from a dispersed amylaceous substance, urea and an alkali metal acetate, the urea and alkali metal acetate each being present in amts. in excess of about 5% of the total solids, the proportions of the ingredients in the compn. being such as to produce flexible, clear, dried films thereof having re-tack properties when moistened. Numerous examples are given.

Adhesive wrapping material of gelatinized cellulosic materials and derivatives, etc. Richard G. Drew (to Minnesota Mining & Mfg. Co.). U. S. 2,183,330, Dec. 12. Numerous examples are given of the production of wrappings for foods, etc., which may comprise a transparent sheet of regenerated cellulose or a cellulose ester or ether the joints of which may be sealed (suitably by use of an applied overlying separate sealing tape if desired) by use of rubber compns., etc.

Polyoxyalkylene ether acid compounds containing a higher aliphatic group (washing, wetting, emulsifying and softening agents, etc.). Hans Haussmann, Walter Scheufler and Josef Kaupp (to I. G. Farbenind. A.-G.). U. S. 2,183,853, Dec. 19. Various examples with details are given of the production of compds. such as the triethylene-glycol-α-dodecyl ether-ω-acetic acid, the bis-ethylene glycolic acid mono-oleyl amide and the diethylene glycol-α-dodecylether-ω-monomaleic acid ester, and similar compds., suitable for use as wetting agents and assistants in dyeing processes, etc.

Condensation products of hydrolyzed protein material suitable for use as wetting agents, etc. Georg Meyer (to General Aniline Works). U. S. 2,183,856, Dec. 19. Products comprising a mixt. of aminocarboxylic acids obtainable by totally hydrolyzing protein materials such as skin waste and acylated with high mol. aliphatic sulfonic or sulfaminic radicals, are suitable for use in various textile treatments, etc.

Producing carbohydrate fatty acid esters from starch-factory by-products. Sidney M. Cantor (to Corn Products Refining Co.). U. S. reissue 21,291, Dec. 12. A reissue of original patent No. 2,147,241 (*C. A.* **33**, 3930[2]).

Synthetic leather-resinous composition suitable for lacquer manufacture or molded products. Willett C. Pierson (to National Products Corp.). U. S. 2,184,467, Dec. 26. Vegetable tanned leather is heated at about 88–93° with H_3PO_4 to form an emulsion; the stuffings are removed from the emulsion; triethanolamine is added at a temp. of about 93°; an aq. mixt. of phenol and $(CH_2)_6N_4$ is heated to about 115°, and the leather residue is added to the aq. phenolic mixt. while maintaining the temp. at about 100° to form a homogeneous mass.

Halogenated ethylene polymers. Eric W. Fawcett (to Imperial Chemical Industries Ltd.). U. S. 2,183,556, Dec. 19. By a reaction such as that of Cl or Br on polymerized C_2H_4 in CCl_4, a product is obtained which is suitable for use in elec. insulation, etc.

Polymerizing vinyl esters such as vinyl acetate. Alfred W. Downes (to Carbide and Carbon Chemicals Corp.). U. S. 2,183,642, Dec. 19. A vinyl ester of a lower satd. aliphatic acid is polymerized when dissolved in MeOAc, which facilitates a high degree of polymerization of a high proportion of the ester. The polymerization may be effected by heating to 60–65° for 12 hrs. in the presence of diacetyl peroxide as a catalyst.

Washing composition. Kurt Sponsel and Karl Daimler (to Kalle & Co. A.-G.). U. S. 2,184,171, Dec. 19. A compn. suitable for use in washing processes comprises an alkali metal salt of a naphthalene sulfonic acid or a substitution product together with a water-sol. cellulose ethyl ether β-sulfonate.

Casein. Lawrence C. Pagel. U. S. 2,184,002, Dec. 19. App. is described, and a process of mfg. casein which consists in intimately and continuously mixing an atomized spray of warm skim milk with an atomized spray of a mineral acid, to obtain a fast and substantially complete curd pptn., suspending the curd in its whey in a defined path of gravitational flow to obtain a curd of substantially uniform acid concn., immediately sepg. the curd from its whey, washing the curd substantially free of all sol. salts, whey and excess acid in three sep. wash waters and then dewatering the curd and drying it.

Oil-resistant compositions for coating paper or cloth, etc., for making cartons or other purposes. William H. Butler (to Bakelite Corp.). U. S. 2,183,234, Dec. 12. A compn. resistant to oils and greases comprises about 2 parts of an oil such as a blown fish oil processed to a Saybolt viscosity at 93° of 75 to 600 having dispersed therein about 1–4 parts of a resinous mixt. comprising 1.5–5 parts of a thermoplastic oxidized resin acid, a coumarone resin or a "novolak" to 1 part of a heat-convertible resin prepd. from a phenol having a hydrocarbon substituent in the ortho or para position, such as "tar acids" and treated with an aldehyde such as CH_2O in the presence of an alk. catalyst, such a compn. softening at a temp. of about 80–93° to a condition suitable for coating. Several examples with details are given.

Coating for skis. James E. Flint. U. S. 2,184,182, Dec. 19. A liquid ski dressing is formed of celluloid 0.5 oz., acetone 1/3 pint, shellac 1/6 pint and powd. graphite 1/12 oz.

Panels of materials such as wood veneers. Arthur R. Welch. U. S. 2,183,599, Dec. 19. App. is described, and a process of mfg. panels from materials incorporating a binder setting under heat and pressure, such as a resin, which involves disposing such materials in side-by-side relation, interposing between certain panels a cool, loose plate of heat-conducting metal such as Al, iron or steel, which is independent of all other such plates, subjecting the panels and plates to pressure and surrounding them with a heated fluid such as hot air or steam to heat the plates, and hence the panels, from the edges inwardly

for a time sufficient to set the binder in the center of each panel, and then surrounding the plates and panels with a cooling fluid and subsequently releasing the pressure on the cooled panels at a temp. below that of steam formation.

Strip-form packing material suitable for use with rotating shafts, etc. Gustav E. Schwarz. U. S. 2,184,087, Dec. 19. Various structural and mfg. details of a packing which may be formed of synthetic rubber, etc.

Decalcomania. Ferdinand W. Humphner (to Mid-States Gummed Paper Co.). U. S. 2,183,315, Dec. 12. A paper base carries a water-sol. adhesive, an overlying transfer body and a partially water-sol. imprint on the latter, the imprint being unaffected by the normal contact with water necessary for releasing the transfer but being substantially impaired by prolonged contact with water beyond such period.

Decalcomania transfer. Frank Hart. U. S. 2,184,077, Dec. 19. A transfer is made comprising a decalcomania paper carrying a water sol. film on a surface thereof, a water insol. adhesive film upon the water sol. film, a sealer film on the surface of the water insol. film opposite the water sol. film, the sealer film adapted to have applied thereon a transfer design, and whereby when the decalcomania transfer is wetted, the water sol. film is released from the water insol. adhesive film for application of the adhesive film to an object.

Sound-record blanks. Harry E. Hofmann (to Union Carbide and Carbon Corp.). U. S. 2,184,524, Dec. 26. A record blank adapted to have sound recorded thereon contains a substantial proportion of a resinous constituent consisting of a vinyl resin at least in the surface of the record upon or in which surface the sound is to be recorded, the vinyl resin being from the group consisting of polymerized vinyl esters of aliphatic acids, polymerized vinyl halides, polymerized vinyl benzene, and products of the conjoint polymerization of a plurality of vinyl compounds of at least two different members within the foregoing group.

Material suitable for use in valves. Julian A. Campbell and Samuel C. Carter. U. S. 2,183,547, Dec. 12. A mixt. of flattened Pb shot 40, ground Pb 40 and ground graphite 20% is used with rosin and oil.

Antifreeze solution suitable for use in engine-cooling systems. Ollie M. Williams, James W. Baker and Benjamin F. Butler. U. S. 2,183,178, Dec. 12. $CaCl_2$ 20 lb., water 5 gal., glycerol 5 pints, KI 1 oz. and the juice of 4 lemons are used together.

Detoxication of plant juices such as cashew nutshell liquid. Martha B. Cayo (to Durite Plastics, Inc.). U. S. 2,183,957, Dec. 19. To decrease or eliminate the "poison-ivy effect" of a material such as cashew nutshell liquid, it is treated with a protein material such as egg or blood albumin, fibroin, keratin or gelatin (suitably with heating after the protein material has been moistened with a hydrolyzing agent) or with aminoacetic acid or other amino acid. U. S. 2,183,958 relates to similar detoxication by heating the material with acetamide, benzamide, carbamide, biuret, formamide, oxamide or succinamide.

Luting composition. Ernst Schnabel. Ger. 684,836, Dec. 6, 1939 (Cl. 47*f*. 22.10). To polyvinyl alc. is added a softener, especially water adsorbing agents, e. g., glycerol; strengthening fillers or binding materials may be added.

Exothermic mixtures suitable for use in hair-waving heating pads or the like. Ferdinand Racen and Walter M. Bruner (to W. G. Shelton Co.). U. S. 2,183,587, Dec. 19. There are used together a primary metal such as Al and a secondary metal such as brass (the primary metal being from the group of stable metals positioned above the secondary metal in the electromotive series of metals, and the secondary metal being from the group of stable metals no more active than Zn and its active alloys), a substance, such as salicylic acid, giving an acid soln., and an oxidizing agent such as $KClO_3$ in sufficient quantity to oxidize both metals. Various examples are given.

Cold permanent waving of hair. David J Pye. U. S. 2,183,894, Dec. 19. A method of waving hair upon the human head involves dividing the hair into compact strands, wetting it with an aq. soln. of an alkali metal sulfide at a pH of 8–11, winding the hair strands and securing the wound strands to impart a permanent wave in about 5 min. to the hair, and finally removing any residual aq. soln. from the hair.

Pest exterminator. N. V. de Bataafsche Petroleum Maatschappij (Henricus Jacobus Charles Tendeloo and Siegfried Leonard Langedijk, inventors). Ger. 684,988, Dec. 9, 1939 (Cl. 45*l*. 3.01). Sulfides contg. the group C.S.C and derived from unsatd. aliphatic or alicyclic hydrocarbons or their derivs. are employed alone or together with other materials.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water poisoning in man and animal, together with a discussion on urinary calculi. Douw G. Steyn and Norman Reinach. *Onderstepoort J. Vet. Sci. Animal Ind.* **12**, 167–230(1939).—From the results of expts. conducted by various workers and the analysis of specimens of water and observations made by S. and R., it appears that the extreme limit of the total salt content of drinking water, especially for human beings, should be 570 p. p. m. This limit depends to a large extent on the nature and quantity of the respective salts present and the suitability of each mineralized water for drinking purposes should be considered on its own merits (analysis). The most poisonous ingredients of mineralized waters are nitrates, sulfides and fluorides, while Mg, Ca and sulfates tend to upset the normal processes of mineral metabolism. The carbonates and bicarbonates of Na and K render the gastrointestinal juices abnormally alk., disturb digestive processes and cause the deposition of urates in the kidneys. Methods of preventing poisoning by water are discussed. Numerous references. K. D. Jacob

Hot springs near Freiberg. Rudolf Schreiter. *Mitt. Naturw. Ver. Freiberg* **3**, 17–19(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 86.—The temp. of the waters and the depths and rocks from which that water comes, of 6 mineral springs are compared and discussed. C. A. Silberrad

Physicochemical and biological studies on some Bulgarian mineral waters. M. Andreïcheva Vankova and D. Kalcheva. *Ann. univ. Sofia*, II. *Faculte phys.-math.*, Livre 2, **34**, 411–44 (in French, 445–6)(1937–38).—The mineral waters of the region around Sofia (Sofia, Gorna, Bania, Kniajevo, Ovtcha-Koupel and Bankia) are weakly alk. Boiled, they become more alk., depending on the amt. of H_2CO_3 dissolved in the H_2O and on the alk. reserve. All these waters have a weak elec. cond.; all, except those of Kniajevo, affect the action of the blood and liver catalases. Those of Ovtcha-Koupel affect the activity of all enzymes except saliva. All have a catalytic action decompg. H_2O_2. After boiling, this catalytic action is more pronounced but of less duration. They also have an action similar to that of oxidases but unlike that of peroxidases. They exercise an influence on the spontaneous oxidation of hydroquinone and of pyrogallol. This effect is stronger after the waters have been heated or boiled. 31 references. A. H. Krappe

The effect of time and temperature of storage on the results obtained in the bacteriological analysis of water. Theodore W. Keiper and John S. Flinn. *Am. J. Med. Tech.* **6**, 11–14(1940).—One hundred samples of water were tested by standard methods at 1 hr. (control), 24 hrs. and 48 hrs. after collection, being stored at room temp. The results show a definite increase in plate counts and in *E. coli* as compared with the control. According to the standards of the Amer. Public Health Assoc., K. found

that water after 24 hrs.' storage was "unsafe for human consumption," and after 48 hrs. it is "bad water." These results indicate that storing water samples at room temp. for any length of time before the beginning of the analysis is not a reliable procedure for judging the character of the water supply. Dorothy A. Meyer

Determination of fluorine in the potable waters of Valsugano in Trentino. Dino Eccher Dall'Eco. *Ann. chim. applicata* **29**, 340–4(1939).—Using a micromethod developed by von-Fellenberg (*C. A.* **33**, 2631[9]), E. has detd. the F content of the drinking waters in the Trentino district. The amts. varied from 0.06 to 1.70 mg./l. A total of 122 samples from as many sources was examd. A. W. Contieri

Water-treatment problems. J. B. Baty. *Can. Engr.* (*Water and Sewage*) **78**, No. 1, 12, 56(1940).—A review. Ann Nicholson Hird

Economies effected by water conditioning. A. H. Ullrich. *Proc. 9th Ann. Arkansas Water & Sewage Conf., Fayetteville*, **1939**, 23–9. E. H.

The use of aluminum sulfate and ferric chloride in the clarification of water. Mario Franco. *Atti soc. med. chir. Padova* **17**, 164–210(1939). Helen Lee Gruehl

Coagulation [in water treatment]. Otto M. Smith. *Proc. 9th Ann. Arkansas Water & Sewage Conf., Fayetteville*, **1939**, 45–54.— A review. E. H.

Chlorination of condenser-cooling water. R. B. Martin. *Trans. Am. Soc. Mech. Engrs.* **61**, 651–6(1939); cf. *C. A.* **32**, 8647[8].—Chlorination is used for the control of algae. C. B. Jenni

Rapid sand filters—today. G. W. Paulette. *Proc. 9th Ann. Arkansas Water & Sewage Conf., Fayetteville*, **1939**, 15–23. E. H.

Recirculation of boiler water to hot-process softeners. John J. Maguire and W. J. Tomlinson. *Combustion* **11**, No. 3, 26–32(1939).—Recirculation of boiler blowdown water to hot-process softeners, either of lime-soda or phosphate types, is discussed. Return to coagulation tanks is used for alky. adjustment prior to filtration. Recirculation of boiler water may be substituted for soda ash used in conjunction with alum in condensate oil removal systems. Operating conditions and equipment available det. the necessary blowdown equipment and control. C. B. Jenni

Rigid and elastic base-exchange materials. H. Pallmann. *Soil Research* **6**, 21–48(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 126–7.—Base-exchange materials are divided into 2 classes: The first includes compact materials of rigid structure with less exchange capacity, less power to retain the adsorbed ions, and greater reaction velocity; this class includes feldspar, mica, kaolinite, aged and much dehydrated gels of SiO_2, Al_2O_3, Fe_2O_3, etc. In the second class are internally dispersed exchange materials with rigid or elastic structure, of greater exchange capacity and greater power of retaining adsorbed ions. Those of rigid structure include permutites and zeolites, those of elastic structure clays of the types of montmorillonite, beidellite and nontronite. C. A. Silberrad

The development of the exchange softening (of water) on the basis of ten years' operating experience in Leuna. E. Seyb. *Chem. Fabrik* **1940**, 30–4.—Saale river H_2O, high in salts and hardness, is reduced to at least 0.1° hardness to use in boilers at 45 atms. pressure. Experiences with silicate, C and synthetic resin softeners are reviewed in respect to efficiency, filter capacity, and effect of temp., pH and mech. abrasion on the material. The synthetic material (cf. *C. A.* **33**, 1746[6], 8417[3,5]) has given the best results. J. H. Moore

The formation of scale and methods of prevention in water heaters. J. M. Krappe. *Gas* **16**, No. 2, 19–22 (1940).—In ordinary domestic hot-water service, scale forms slowly when the water temp. is maintained by means of a thermostat at 140°F. or below. At 180°F. scale formation was found to be 7 times as great in one instance. Hence, furnace coils and side-arm heaters are more prone to scale formation than automatic water heaters. When water at 180°F. or higher is required, scale formation can be prevented by adding hexametaphosphate to the water at the rate of about 2 parts per million, by means of a wick or by-pass feeder, a feeder using a porous cup, or some similar device. A metaphosphate of low soly. is commercially available which can be placed directly in an enlarged portion of the supply line provided with suitable corrosion-resistant screens, and will dissolve at such a rate as to give suitable metaphosphate concns. R. W. R.

Attack on steel in high-capacity boilers as a result of overheating due to steam blanketing. Everett P. Partridge and R. E. Hall. *Trans. Am. Soc. Mech. Engrs.* **61**, 597–622(1939).—A no. of failures in boilers operating in the pressure range near 1400 lb. per sq. in. have occurred under conditions such that O corrosion or scale could not be considered as the cause. The tubes have shown internal attack along the top, generally with definite grooving and the production of black magnetic iron oxide. The fundamental cause of this type of failure is steam blanketing. In a tube slightly inclined to the horizontal, the steam tends to rise to the top and move along it. This introduces a resistance to the flow of heat from the tube wall to the fluid, and causes the top of the tube to become more or less seriously overheated. Boiler water of normal alky. passing through the tube and touching the overheated surface is concd. to an excessive degree, with resultant attack on the steel. It has been shown that the rate of oxidation by H_2O at high boiler temps. is greatly accelerated by increase in concn. of NaOH. Elimination of caustic alky. from the boiler water retards the action but does not affect the fundamental cause, and may merely postpone the trouble. The best chance of obviating the difficulties which may result from steam blanketing is to design the surface exposed to high rates of heat input so that steam blanketing cannot occur, or where slightly inclined tubes must be used, to protect them so that the rate of heat input will be sufficiently low to avoid excessive overheating of the metal. C. B. Jenni

Feedwater-treatment problems with high-pressure boilers. E. A. Sitter and W. J. Massey. *Natl Engr.* **44**, 102–5(1940).—Feedwater for 700-lb. pressure boilers must be completely deaerated, zero hardness must be maintained at all times together with accurate control of alky. and total solids. To maintain zero hardness phosphate is fed directly to the boilers through feeding equipment installed along with the deaerating heater. A. N. H.

Present-day boiler-water treatment. H. Richter. *Atti V° congr. intern. chem.* **4**, 320–9(1939).—The recent improvements in boiler-water treatment include a new phosphate treatment process devised by Chem. Fabrik Budenheim A.-G. (cf. *C. A.* **33**, 5559[6]) and new exchangers for bases. The problem of SiO_2 removal and recent elec. processes for the prevention of deposits on boiler walls are also discussed. A. H. Krappe

The joint meeting for sewage disposal of certain municipalities in Essex and Union counties, New Jersey. Leslie E. West. *Sewage Works J.* **11**, 1067–74(1939).—Data are summarized from the annual report for 1938. W. D. Hatfield

Operating problems in starting the southwest plant of the sanitary district of Chicago. A. H. Goodman, C. T. Mickle, G. G. Poindexter and Roy C. Hageman. *Sewage Works J.* **11**, 1020–37(1939). The paper is divided into sections on treatment problems, chem. control and mech. organization. Of particular interest are the low air requirements and short aeration periods which have been possible. Chem. control consists of detg. dissolved O, sludge index, sludge return concns. and suspended solids in the mixed liquor. The plant is unique in that it is operated on a const.-flow basis, the excess flow being treated in the West Side Plant. W. D. Hatfield

Sewage disposal in Canada. Albert E. Berry. *Can. Engr.* (*Water and Sewage*) **78**, No. 1, 11–15, 46–50(1940). Ann Nicholson Hird

Sewage disposal works for Barrie, Ontario. G. Graham Reid. *Can. Engr.* (*Water and Sewage*) **78**, No. 1, 13, 56–7(1940). Ann Nicholson Hird

Treatment of septic-tank effluent from a small community by means of an enclosed biological filter at Bloemsfontein, South Africa. Hugh Vaughan Davies. *J. Inst.*

Civil Engrs. (London) **1939–40**, No. 2, 155–8; cf. *C. A.* **33**, 3504⁹.—Reply to correspondence. A. N. H.

High-capacity trickling [sewage] filters. L. E. Livingston. *Proc. 9th Ann. Arkansas Water & Sewage Conf., Fayetteville*, **1939**, 30–3.—A review. E. H

Filtration and incineration at Buffalo. C. R. Velzy. *Sewage Works J.* **11**, 988–93(1939).—The primary sludge is stored in digestion tanks of 20-day retentive capacity. The filters are operated at a rate of 5 lb. of dry solids per sq. foot per hr. Difficulties are reported from grease depositing in the 10″ sludge force main. Grit as well as sludge is incinerated. Fouling of sludge-conveyer belts is reported. W. D. Hatfield

Studies in the methane-producing bacteria. IV. Growth of methane-producing organisms in supernatant sludge liquors. H. Heukelekian and Bernard Heinemann. *Sewage Works J.* **11**, 965–70(1939); cf. *C. A.* **33**, 9505⁸.—The supernatant liquors from fresh and ripe 3 sludges, when used as culture media, allowed the max growth of methane-producing bacteria, and septicization for even 2 days limited the growth of these organisms owing to the production of inhibitory substances. Complete digestion either destroys these inhibitory substances or overcomes their activity with growth-promoting substances. W. D. Hatfield

Fine screening of sewage. Joseph A. Muldoon. *Sewage Works J.* **11**, 1054–66(1939).—The design, operation 4 and maintenance of mech. fine screens of the Reinsch-Wurl type are fully discussed with particular emphasis on the maintenance of screens, brushes, thrust bearings, sleeves and proper lubrication. W. D. H.

Sludge-gas-engine operation at Michigan City, Indiana H. H. Jones. *Sewage Works J.* **11**, 1074(1939).—A preliminary report. W. D Hatfield

Activated-sludge oxidations. IV The influence of temperature upon the rate of oxygen utilization by activated sludges Clair N. Sawyer and Gerard A. Rohlich. *Sewage Works J.* **11**, 946–64(1939); cf. *C. A.* **33**, 9505⁸.—For 5 activated sludge alone, the av. rates at 20, 15 and 10° were found to be 71.2, 45.2 and 25.5% of that at 25°. The equation, $y = 0.71x^{1.54}$ in which y is the relative activity in percentage based on the value at 25° = 100% and x is °C., has been found to apply. The rate of O utilization was independent of nitrification. Winter sludges used more O at given temps. than summer sludges. Fourteen graphs are given showing the temp. effect on O utilization of sludges from different sources and seasons. W. D. Hatfield

Sludge disposal at the Minneapolis-St Paul plant. George J. Schroepfer. *Sewage Works J.* **11**, 971–87 (1939).—This part of the plant consists of sludge-concen tanks, bucket elevators, chem.-treatment tanks, vacuum filters and multiple-hearth incinerators. The initial operation difficulties are described. Sludge of more than 8–10% solids does not flow easily. Production of thick cakes was found inadvisable. Auxiliary fuel oil was not found necessary for operation of the incinerators; in fact excess heat had to be dissipated to keep furnace temps. down. The total cost per dry ton of sewage solids during the last 6 months was $3.30 for operation and maintenance. W. D. Hatfield

Sewage treatment at Gary. L. R. Howson. *Sewage Works J.* **11**, 994–1005(1939).—This new plant consists of primary sedimentation, activated sludge, sludge digestion, gas engines for pumping sewage, electrically driven blowers and sludge-drying beds. W. D. Hatfield

Development of flash drying system of sewage sludge at the sanitary district of Chicago Wm. A. Dundas. *Sewage Works J.* **11**, 1006–19(1939).—The theory and development of the flash drying system are described. Either dried fertilizer or complete incineration is possible. No operation or cost data are given. W. D. Hatfield

Studies on activated-sludge bulking. I. Bulking of sludge by means of carbohydrates. R. S. Ingols and H. Heukelekian. *Sewage Works J.* **11**, 927–45(1939).—With a deficient amt. of N the development of zoögleal organisms is limited to the amt. of N present. The development of *Sphaerotilus* is favored by the excess of carbohydrate left in soln. Bulking due to sugar in soln. is partially caused by a deficiency in N and also by the much greater rate of growth of *Sphaerotilus*. Peptone produced a heavy growth of zoögleal organisms but did not favor *Sphaerotilus*. Bulking is the result of the successful invasion of the facultative anaerobic (*Sphaerotilus*), over an aerobic organism (zoöglea), so that the smaller the quantity of O present the more rapid the bulking. W. D. Hatfield

Excerpts from "Minneapolis-St. Paul sanitary district report for 1938." Geo. J. Schroepfer. *Sewage Works J.* **11**, 1078–83(1939). W. D. Hatfield

Extracts from first annual report of the Buffalo sewer authority 1938–1939. Charles R. Velzy and G. E. Symons. *Sewage Works J.* **11**, 1085–8(1939). W. D. Hatfield

Studies on the digestion and distillation of organic wastes. VII. Characters of the fuel oils derived from the distillation of egg albumin and egg yellow. Saburo Sibata. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 336–7(1939); cf. *C. A.* **33**, 7940³.—Boiled egg albumin dried at 100°, with 40% Japanese acid clay, on distn. gave NH_4 salts but no tarry matter. Egg yolk similarly treated gave a brownish grease. The first is like that from digested sludge, the second like that from undigested sludge Yields of 10 and 48% of "fuel oil" of given elementary analyses were fractionated. They contained 72.8 and 36.4% unsatd. compds., 19.7 and 35.6% aromatic compds., and 7.5 and 28.0% naphthenes and paraffins. The results confirm a prior assumption that "fuel oil" from raw settled sludge may be due to raw fatty matter content **VIII. Digestion of garbage, soybean and starch (former two materials are digested so as to prevent the evolution of combustible gases) and the distillation of digested residues thereby obtained.** *Ibid.* 338–41.—Mixed garbage 5 with 14.4% digested sludge when digested with or without acid clay anaerobically gave no H or CH_4 and the pH remained below 7.0 except for a brief time when dosed with lime to above that level at 50–60 days. Volatile solids were liquefied rather than gasified. Boiled soybean with acid clay and starch with acid clay similarly seeded and treated gave no CH_4 but H from the latter in a ratio of 2:1 to the CO_2 evolved. "Fuel oil" yields on distn. of the residues were 22.9, 16.0, 23.3 and 2.8%, resp. The first 6 2 are double the theoretical from Et_2O-sol. substances present in the material retorted. Therefore much must have come from "Kerogen." Reduction of combustible gas thus increases liquid-fuel yield. The "fuel oil" from soybean residues was smaller than the theoretical value; anaerobic digestion may reduce rather than increase yields from it. The digested starch residue gave 3% of light oil and 9% of "fuel oil" when distd. with 10% reduced iron 7 powder. Foster Dee Snell

Packinghouse wastes and sewage treatment at Austin, Minnesota. Paul Hansen and K. V. Hill. *Sewage Works J.* **11**, 1045–53(1939).—The problem at Austin is the treatment of sewage from a human population of 18,000 and a waste population equiv. of 195,000. The latter waste is to be pretreated by the industry with sedimentation and high-rate filters to reduce it to a population 8 equiv. of 62,000 and thus make the total strength entering the city plant 80,000. The city plant consists of chem. treatment, flocculation, sedimentation, high-rate filters, intermediate sedimentation, final filters and final sedimentation. The design is very flexible so that various steps in the treatment can be eliminated when river stages require less complete treatment. An interesting feature is an equalizing tank which will allow the plant to be operated at an av. daily const. rate of flow. W. D. Hatfield

Treatment of sulfur-dye waste by the activated-sludge process. III. Dewatering of activated sludge obtained by treatment of a sulfur dye-sewage mixture. Ralph Porges and Henry J. Miles. *Sewage Works J.* **11**, 1038–44(1939); cf. *C. A.* **33**, 1848².—Approx. twice as much (8·4%) $FeCl_3$ was required to condition activated sludge from sewage and dye mixts. as was required with activated sludge from sewage alone. Fresh activated sludge filtered better than sludge stored overnight. W. D. Hatfield

Pulp mills and fisheries (Vallin) **23**. Rubber as construction material [for mains, conduit pipes, taps, etc.] (van Wijk, Jr.) **30**. Geol. foundations of hot springs of Johannisbad (Watznauer) **8**. Oxidation-reduction potentials in water-logged soils, natural waters and muds (Pearsall, Mortimer) **15**. Improvement in detn. of Li in mineral waters (Hackl) **7**. Contamination of water by waste liquors of sulfate pulp mills (Bergström, Vallin) **23**. 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

Soils of Musselshell County, Montana. L. F. Gieseker. *Montana Agr. Expt. Sta., Bull.* **374**, 3–50(1939).—Soil survey data are given. C. R. Fellers

Boone County soils. Herman Wascher, R. S. Smith and L. H. Smith. *Illinois Agr. Expt. Sta., Soil Rept.* **65**, 35 pp. (1939).—In most soils of the County, N is the most important limiting factor for plant growth; this is especially true for the lighter soils developed under forest vegetation. Available P is also low in many soil types. Productivity indexes for the several types are given. C. R. Fellers

Shelby County soils. Herman Wascher, Guy D. Smith and L. H. Smith. *Illinois Agr. Expt. Sta., Soil Rept.* **66**, 48 pp. (1939).—Chem. deficiencies are principally Ca, N and P. Productivity indexes for the several soil types are given. C. R. Fellers 5

Soil surveys of Saskatchewan irrigation projects. H. C. Moss. *Sci. Agr.* **20**, 170–4(1939).—Detns. of exchangeable bases, vol. wt., moisture-holding capacity and wilting coeff. are of direct value in the study of irrigation problems. C. R. Fellers

Nature of soil parent materials in southern British Columbia. C. C. Kelley. *Sci. Agr.* **20**, 301–7(1940).—Geol. C. R. Fellers 6

Composition, rating, and conservation of Willamette Valley soils. W. L. Powers, J. S. Jones and C. V. Ruzek. *Ore. Agr. Expt. Sta., Bull.* **365**, 38 pp. (1939).—There is a deficiency of S in many of the basaltic soils. Most of the soils respond to N fertilization. The ratio of K to Ca increases with soil age, i. e., soils lose Ca faster than K. The Mg content is normally 50% that of the Ca. A productivity rating of the soils is given. C. R. Fellers 7

Some Bulgarian soils. II. K. Woynoff. *Bodenkunde u. Pflanzenernahr.* **16**, 12–16(1939); cf. *C. A.* **33**, 2259⁶.—Partial analyses of 33 samples are tabulated. Only one contained acid humus, as indicated by the color of an NH_4OH ext.; the same and one other soil were acid to litmus paper. Extremes of compn. were represented by total C, N and humus contents of 0.06, 0.06 and 0.10, and 3.05, 0.36 and 5.25%, resp. The max. $CaCO_3$ content was 31.3%; several samples contained none. C. J. Schollenberger 8

Soil moisture studies. I. Some factors affecting the moisture-holding capacity and its determination. J. C. Wilcox. *Sci. Agr.* **20**, 140–9(1939).—The moisture-holding capacity was affected by the type of soil, time after irrigation, depth of sampling and type of subsoil. Great variability existed in water-holding capacity in a single soil type. A lab. method was developed that approximated field results closely. The soil was tamped in 2 × 3 in. tubes with a standard degree of packing, satd. with H_2O, and drained for 30 min. over air-dry soil of the same kind packed in a similar manner. C. R. Fellers 9

Method of taking soil monoliths. R. H. Spilsbury. *Sci. Agr.* **20**, 297–300(1940).—A trough with galvanized Fe sides, open at 1 end, is forced into the exposed soil section by means of a jack, thus preserving the soil monolith in its natural state without the use of cementing materials. C. R. Fellers

Dispersion of lateritic soils and the effect of organic matter on mechanical analysis. O. W. Beale. *Proc Assoc. Southern Agr. Workers* **40**, 59–60(1939).—Suspensions of certain lateritic soil dispersed with Na oxalate were frequently unstable. A study of suspensions dispersed with Na oxalate and NaOH, separately and in various combinations, showed that best results are obtained by using 5 ml. 0.5 *N* Na oxalate and 3 ml. *N* NaOH per l. The H_2O_2 pretreatment can be omitted on most lateritic soils. Also in *Soil Sci.* **48**, 475–81(1939). K. D. J. 4

Mineral composition of soils and forage crops in Eastern Canada. I. Timothy hay and oat straw. L. E. Wright, J. C. Woodward and C. H. Robinson. *Sci. Agr.* **19**, 673–86 (1939).—Paired samples of timothy hay, oat straw and soil showed that there was no relationship between Ca and P content of timothy hay or oat straw and the exchangeable Ca and sol. P of the soil. There was a pos. correlation of the N of timothy hay with the N of the soil. The relationships between exchangeable Ca and pH of soil were pos. and were significant at the 1% point. The Ca content of both hay and straw was significantly greater when the crops were grown on sandy loams than when grown on clay loams. The clay loam soils were higher in total Ca, exchangeable Ca and sol. P than the sandy soils. There was some evidence that P fertilizers increased the P content of hay and straw when soil P was low. Reported instances of mineral deficiences in livestock were not related to Ca or P content of hay or straw. C. R. F.

The heats of reaction of some humic acids. Erhard Jung. *Bodenkunde u. Pflanzenernahr.* **16**, 129–37(1940).—The results of calorimetric detns. by a technique similar to that of Wust and Lange (*C. A.* **19**, 3412) on solns. of Na humate extd. from high-moor peat with NaOH and NaF (cf. *C. A.* **32**, 9359⁷) and Merck's "humic acid" were irregular and inconclusive, exceeding the values for total heat of neutralization calcd. from the acidity. No measurable heat of dissocn. could be demonstrated with any of these substances. Fifteen references. C. J. Schollenberger 8

Pycnometric determination of water content and specific gravity of soil. Alexius Jung. *Bodenkunde u. Pflanzenernähr.* **16**, 137–40(1940).—The use of a special pycnometer with accurately ground-on neck graduated 53–56 ml. over a 16-cm. length is described. To a 10.00–11.00-g. sample weighed into the wide-necked body is added about ½ of 50.00 ml. H_2O at room temp. and a vacuum briefly applied with gentle agitation to remove air bubbles. The pycnometer is then assembled and the remainder of the H_2O added. The vol. of soil + H_2O observed is calcd. graphically to 20° standard temp.; this figure $-50 = v$. Then from the sp. gr. of the dry soil (s) and the wt. of the damp sample (g), the percentage of H_2O in the sample (y) is calcd., $y = (v - (g - v)/(s - 1))$ 10. Similarly, the 9

vol. of dry soil (x) is calcd., $x = (g - v)/(s - 1)$. With a table and by always using a 10.00-g. sample, the results can be read without calcn., or by constructing a nomogram the necessity of using exactly a 10.00-g. sample can be avoided; the sample may be any known wt. of 10–11 g. Comparisons with the standard oven-drying method on numerous soils showed agreement within less than 0.1% in every case; the pycnometric method generally indicated a slightly higher H_2O content. C. J. Schollenberger

Oxidation-reduction potentials in water-logged soils, natural waters and muds. W. H. Pearsall and C. H Mortimer. *J. Ecol.* 27, 483–501(1939).—In wet soils and muds, the diphenylamine reaction for nitrates is pos. and replaceable ferrous Fe disappears above a potential of 350 mv. at pH 5. In natural waters, ferrous Fe is detectable only below this potential, while below the same point NH_3 tends to replace nitrate and sulfides to replace sulfates. This potential is found in these waters at low O concns., equiv. to about 8% of satn. or less. The apparent potentials estd. with various oxidation-reduction indicators agree with the electrode potentials in the crit. range. Data are given for the effects of O on the drifts of potential. J. R. Adams

Standardization of rapid soil-testing technique. C. P. Rivaz and G. C. McLaren. *Sci. Agr.* 20, 120–30(1939).—A shaking device and a rotator for minimizing variations in manipulation are described. Permanent standards, used in conjunction with a suitable illuminator, simplify the reading of the tests and assist in eliminating errors in matching colors caused by the personal factor. Rapid soil tests can be made with a fair degree of accuracy if simple precautions are observed. C. R. Fellers

California practice in obtaining undisturbed soil samples. T. E. Stanton, Jr. *ASTM Bull.* No. 101, 9–12(1939).—Two types of soil samplers are used, a heavy power-operated sampler for depths ranging up to 300 ft. and a hand-operated sampler for depths up to 50 ft. The salient feature of the drill consists of a bit which plugs the sampler and which may be retracted through the sampler leaving the open end to be driven into the undisturbed soil to the desired depth. John O. Hardesty

A method for rapid titrimetric determination of ferric oxide and alumina following precipitation by 8-hydroxyquinoline from soil extracts and its application to the recognition of horizons of enrichment. P. Pfeffer. *Bodenkunde u. Pflanzenernahr.* 16, 50–8(1939).—To 5–30 g. soil in a 200-ml. Erlenmeyer flask add 25 ml. HCl, sp. gr. 1.15, with 1 ml. 30% H_2O_2 and boil ½ hr. Dil. and filter into a 100-ml. volumetric flask, washing with dil. HCl to recover Fe; add NH_4OH just short of permanent pptn., cool and dil. to 100 ml. To a 25-ml. aliquot add 30 ml. aq. soln. contg. 13% NH_4 tartrate and 10% NH_4OAc, some filter pulp and 30 ml. 65% AcOH and heat to 80°; next add from a buret with shaking a 4% soln. of 8-hydroxyquinoline (**B**) in 10% AcOH, testing drops with $FeCl_3$ to ensure an excess. Record the exact vol. of **B** added; its titer vs. 0.1 N $KBrO_3$ must be known. Let stand 24 hrs., dil. to 150 ml. and filter with dry glassware (**A**). The filtrate should be yellow with little green; if deep green, return to the flask and let stand another day with frequent shaking before filtering. Det. excess **B** in a 20-ml. aliquot of **A** plus 20 ml. 25% HCl, by titrating first with 0.1 N $KBrO_3$ in excess, then titrating back with 0.1 N $Na_2S_2O_3$ after adding 2–3 g. KI and starch indicator. One ml. 0.1 N $KBrO_3$ = 0.665 mg. Fe_2O_3. To a 50-ml. aliquot of **A** add 5–10 g. NH_4Cl, heat to 80° and neutralize with NH_4OH, when a part of the Al_2O_3 will be pptd. by the excess of **B** added for the Fe detn.; to complete, add a 2% soln. of **B** in an equal wt. of glacial AcOH, neutralized with NH_4OH and made to vol., testing drops as before to ensure excess of **B**. Add a little NH_4OH to this mixt. and heat on water bath for 5 min., filter and wash with hot water. Dissolve from the filter back into the flask with a 1:1 mixt. of 25% HCl and 96% EtOH, add 20 ml. 25% HCl and titrate **B** in the ppt. as before. One ml. 0.1 N $KBrO_3$ = 0.428 mg. Al_2O_3. Tests on numerous soils showed satisfactory agreement with the detns. by standard methods. Seven references. C. J. Schollenberger

Chemical investigations of a number of soil profiles. Aasulv Løddesøl and O. Braadlie. *Norsk Geol. Tids.* 18, 305–69, 371–3 (in English, 369–71)(1939).—Numerous Norwegian soil samples were analyzed and the results of podzolized profiles prepd. as follows: The relation between the quantity of each oxide in the various horizons and in horizon *A* was calcd. The quotients thus found were arranged along straight lines, one for each horizon. Al_2O_3 is the reference oxide and its place on the line is the zero point. The position of the other oxides indicates the loss (left) or increase (right) in percentages. The loss or increase percentage is traced graphically. In typical saline profiles the content of oxides in the various horizons in proportion to horizon *C* is given. Raw humus on sand (rainfall 400 mm.) is richest in exchangeable ions. Below horizon *A* there is horizon A_2 poor in nutrients and rich in silica; it is followed by horizon *B*, where Fe compds. are pptd., while the monatomic and to a great extent also the diatomic cations are washed out. In profiles of fine sandy soils (rainfall 700 mm.) the soil is poor in plant nutrients, though leaching is not very pronounced. There is formed a horizon enriched in salts, which in addn. to Al_2O_3 and Fe_2O_3 also contains MgO, whereas Ca is pptd. as phosphate in horizon *C*. In saline profiles (rainfall 300 mm.) the contents of easily mobile oxides were lowest in horizon *C*, increasing upwards. They were most abundant in horizon *A*, the readily sol. salts moving up because of the slight rainfall. As for org. soils (rainfall 1800 mm.) it appears that in bog soils a leached profile corresponding to the podzol profiles for mineral soils is formed. Immediately below horizon *A* is the leached horizon *B* with a lower electrolyte content. In the lowest horizon, of greater plasticity, the pH is higher, and the pptd. complexes in the overlying horizon are dissolved and removed with the $CaSO_4$. The increase in the pH, especially in the lowest horizon, is believed to be due to the K content which is not pptd. but proceeds downwards. In surface samples electrodialysis shows that more sulfates and chlorides of monatomic and diatomic cations were given off by the fertilized than by the unfertilized soil, the latter giving off mostly phosphates of Al and Fe. 40 references. A. H. Krappe

The influence of subsoiling and organic matter on eroded Lufkin soils. D. W. Thorne. *Proc. Assoc. Southern Agr. Workers* 40, 59(1939).—Expts. were carried out with the topsoil, 1st 6 in. of the subsoil and various mixts. thereof, to which were added various treatments of lime, vetch and oat straw. The treated soils were maintained at about 50% of their water-holding capacity for 4 months. The low productivity of the subsoil seemed to be due to a deficiency of N and available P, as well as to its undesirable phys. properties. Treatment with vetch greatly increased the content of N and available P and increased the nitrifying power of the various soils. Oat straw had no significant effect on available P in the soils but depressed their content of nitrate and the nitrifying power as expressed by nitrate accumulation from the biol. oxidation of $(NH_4)_2SO_4$. Lime hastened decompn. of the org. matter as shown by an increased accumulation of nitrate. In greenhouse expts. the yields of oats from the treated soils were in agreement with the results secured for available P, nitrate and nitrifying power. K. D. Jacob

The boron content of some Okanagan soils. C. G. Woodbridge. *Sci. Agr.* 20, 257–65(1940).—The observations of McLarty (*C. A.* 30, 8490⁷) that corky core and drought spot in apple trees were due to B deficiency are confirmed. Addns. of B to the soil about the trees is a convenient way of providing B. Approx. 50 lb. of borax per acre is used. Soils should contain 0.5 p. p. m. of B for normal crop requirements. There was fairly rapid diffusion of B in the sandy soils to a depth of 30 in. Various extg. solns. for B in soil were compared. For the extn. of B no difference exists between water alone and water satd. with CO_2. A 1% HCl soln. extd. 1.5–2.5 times as much B as did the others. C. R. Fellers

Recent studies on the nature of soil organic phosphorus. C. L. Wrenshall, W. J. Dyer and G. R. Smith. *Sci. Agr.* 20, 266–71(1940); cf. *C. A.* 33, 8880².—Although

org. soil P bears a chem. similarity to nucleic acids, it differs greatly from such compds. in its susceptibility to decompn. in the soil. The soil compds. are very resistant to decompn. by soil organisms. A definite fraction of the soil org. P is highly resistant to decompn. by alk. hydrolysis. It is very difficult to split off all the phosphate by acid hydrolysis. An improved procedure, by which higher yields of the soil "nucleic acid" fraction are obtained, is described. C. R. Fellers

Arrangements for testing soils for available phosphoric acid by Egnér's lactate method. H. Rheinwald and G. Constantin. *Bodenkunde u. Pflanzenernahr.* **16**, 1–12 (1939).—A detailed description of procedures and app. in a lab. testing 400 samples of soil daily for assimilable P_2O_5 by Egnér's Ca lactate-HCl extn. method (cf. *C. A.* **27**, 3278). C. J. Schollenberger

Phosphorus in the economy of the soil. Ennio Luiz Leitão. *Bol. ministerio agr.* (Brazil) **28**, No. 1–6, 9–14(1939).—Didactic. O. W. Willcox

Cobalt status of soils and pastures in the Sherry and Wangapeka districts, Nelson. D. J. Stanton and E. B. Kidson. *New Zealand J. Sci. Tech.* **21B**, 65–76(1939).—A Co survey of soils and pasture plants indicates that the geological formations considerably influence the Co contents of the derived soils. Soils from Kaiteriteri granite are low in Co and in certain cases stock ailment is definitely assocd. with their grazing on these soils. Low soil Co content is usually reflected in pasture plants growing thereon but there is not always a correlation between Co figures for the 2 Soil contamination of pasture plants interfered seriously with analytical accuracy. The detn of Fe, sol. in HCl, in such plants made calcns. of, and correction for, such contaminations possible. Soils low in Co are often low in other plant elements and addns. of Co will not produce satisfactory results unless the lime and phosphate resources of the soils are also increased F. W. Marsh

Seasonal variation in cobalt content of North Island pastures. K. J. McNaught and G. W. Paul. *New Zealand J. Sci. Tech.* **21B**, 95–101(1939).—Analytical results on monthly samples taken over a 12-month period indicate the Co content of pasture plants increases in late autumn and winter when plant growth is retarded and decreases in spring and summer when growth is at a max. There is also an increase under drought conditions. Tall and mature growth and hay have lower Co contents than closely grazed plants. Plants from bush-sickness areas have a Co content of 0.005–0.17 p. p. m. on dry matter and healthy plants 0.04–0.37 p. p. m. In areas where sheep are affected by Co deficiency the content of closely grazed pasture plants, especially in late spring and summer, falls below 0.08 p. p. m. and remains low for several months. Soil contamination of plant samples complicates the interpretation of results. Although sheep and cattle may benefit from the ingestion of soil on plants it is impossible to est. the amt. of Co in the soil that is made available by digestive juices. F. W. M.

Nitrogen fixation in soil not wholly a bacterial process. N. R. Dhar and E. V. Seshacharyulu. *J. Indian Chem. Soc.* **16**, 557–62(1939).—When glucose is mixed with SiO_2, ZnO, Al_2O_3 and Fe_2O_3 and exposed to air and light, there is appreciable N fixation. Under comparable conditions the N fixation in light is greater than in the dark. When energy materials such as inulin, arabinose, fructose, lactose, glucose, mannitol, glycerol, galactose, maltose, dextrin and starch are mixed with sterile soil in either quartz or Pyrex glass vessels there is appreciable fixation of N even under completely sterile conditions, which is greater in light than in dark and in quartz than in glass vessels under identical conditions. It is concluded that the energy available from the oxidation of glucose or other energy materials can lead to N fixation even in the absence of microörganisms. John O. Hardesty

Potassium and potassium fixation in Louisiana soils. M. B. Sturgis and J. R. Moore. *Proc. Assoc. Southern Agr. Workers* **40**, 56–7(1939).—There is a wide variation in the exchangeable K content of the soils of the Coastal Plain, particularly those of the Kirvin series. Tentatively, Coastal Plain soils would be expected to respond to K fertilizer applied to cotton if the exchangeable K is less than 85–100 p. p. m. The Mississippi, Red and Ouachita terrace soils should respond to K fertilizer if the exchangeable K is not over 100–115 p. p. m. K applied as KCl to the surface soil of Lintonia silt loam and Teller very fine sandy loam could be largely removed from the soil by the base-exchange reactions. Almost half the K added to the soil was sol. in water after a period of 4 months. Addns. of phosphate and lime had no definite influence on the fixation of K. Addn. of org. matter and its subsequent decompn. prevented any fixation of the added K and showed a marked effect on the liberation of native soil K The relatively low absorptive capacities of the soils for K and the ease with which water and H_2CO_3 may remove K through leaching contribute to make the maintenance of available K difficult in soils that leach easily. K. D. Jacob

Fertilizer response and requirements for profitable crop production in the Yazoo-Mississippi delta. Roy Kuykendall. *Miss. Agr. Expt. Sta., Bull.* **333**, 3–11 (1939).—Soils on the west side of the delta respond to N only Most soils on the east side respond to P and K applications as well as N. The N can be added to the soils up to within 10 days of planting time without affecting crop yields. From 30 to 40 lb. per acre gave most economical results. Little differences in yield resulted from the several placement expts. Good mixing of fertilizers in the seed bed is very important. C. R. Fellers

Progress report of phosphate and other fertilizer investigations at the Aberdeen Branch Experiment Station, University of Idaho. John L. Toevs and G. Orien Baker. *Idaho Agr. Expt. Sta., Bull.* **230**, 3–27(1939).—$CaSO_4$ or S gave no yield increases for alfalfa. The amt. of active lime in the soil influences crop response to P fertilization. Phosphates should be applied at the time of seeding clover or alfalfa. Av. yields of red clover seed were trebled by the use of treble superphosphate at 300 lb. per acre. If the soil contains well-balanced amts. of N, P and K, P fertilization for potatoes is not desirable. However, when potatoes follow legumes which are heavy P feeders, and the P has not been replaced, the further addns. are profitable. Sugar beets respond well to P fertilization. From 60 to 120 lb. per acre is recommended C. R. Fellers

Fertilizer and liming practices recommended for South Carolina. H. P. Cooper. *S. Carolina Agr. Expt Sta., Circ.* **60**, 3–23(1939).—The min. total plant nutrient content of mixed fertilizer should be about 20%. The soil acidity problem of S. Car. is a limiting factor in crop production. About 40% of the samples had pH values of less than 5.5, and another 40% was between 5.5 and 6.0 From 0.5 to 1.5 tons of ground limestone per acre distinctly benefits most crops. Common plants are classified as to their tolerance of soil acidity. C. R. Fellers

Crop response to chemical oxidizers. C. R. Harihara Iyer and R. Rajagopalan. *Quart. J. Indian Inst. Sci.* **2**, 171–8(1939); *cf. J. Indian Inst. Sci.* **22A**, 171–8(1939); cf. *C. A.* **29**, 7399[2].—Pot and field expts. with ragi (*Eleusine coracana*) showed that oxidizers such as $KMnO_4$, MnO_2 and Fe_2O_3 have a residual effect on the soil and that succeeding crops derive benefit from the treatments. Mn applied as $KMnO_4$ remained in the acid-sol. state for a long time. The fertilizing action of the oxidizing agents is mainly due to the greater evolution of CO_2 which increases photosynthesis and plant growth. These tests indicate that the loss of org. matter from the soil, owing to increased decompn., is offset by the production of larger crops and the return of more plant residues to the soil. Ragi and tomatoes were benefited by top dressings of Fe_2O_3 and MnO_2. The extent of response to oxidizers depends on the type of org. manure present in the soil. Basal dressings of Fe_2O_3 to soil which was fertilized with hongay cake presumably caused the release of large amts. of plant nutrients before the plants were able to profit therefrom. Compost and stable manure under the same conditions gave better crop response. J. O. H.

Influence of manganese and iron salts on the oxidation

of organic matter and release of plant nutrients. C. R. Harihara Iyer and R. Rajagopalan. *Quart. J. Indian Inst. Sci.* 2, 179–202(1939); or *J. Indian Inst. Sci.* 22A, 179–202(1939); cf. preceding abstr.—Basal dressings of $MnSO_4$ and $KMnO_4$ increased the yields of tomatoes, ragi and French beans. The same was true of sol. Fe salts to a lesser extent. A small part of the sol. Mn salts remained acid-sol. in the soil while the rest was quickly converted to acid-insol. MnO_2 which was responsible for hastening the decompn. of org. matter. The extent of the decompn. of org. matter depends on its chem. compn. Decompn. of org. matter increased with increasing org. matter content of the soil receiving Mn salts. There was a lag in oxidation of humus when heavy dressings of Mn salts were applied; however, after the concn. of sol. Mn had decreased, the decompn. proceeded rapidly. Small applications of Mn salts gave the best crop response. John O. Hardesty

Factors affecting the vegetative cover of Delaware marshes. F. C. Daigh, Donald MacCreary and L. A. Stearns. *New Jersey Mosquito Extermination Assoc., Proc. Ann. Meeting* 25, 209–15(1938).—The approx. optimum salinities for growth in the Delaware marshes were for *Typha angustifolia* 2950, *Scirpus olneyi* 5441, *Spartina alterniflora* 9477, *Spartina patens* 12,112 and *Distichlis spicata* 16,360 p. p. m. The recorded ranges of salinities for the plants were 48–18,150, 1485–10,120, 1012–25,575, 2464–30,800 and 5500–37,400 p. p. m., resp. The max. pH values for the plants ranged from 6.11 to 6.64 and the min. values from 2.96 to 3.90, but the differences between the av. values (4.75–5.10) for each plant were not significant. K. D. Jacob

Effect of ditching for mosquito control on the pH of marsh soils. F. C. Daigh and L. A. Stearns. *New Jersey Mosquito Extermination Assoc., Proc. Ann. Meeting* 26, 39–43(1939); cf. preceding abstr.—In Delaware marshes the pH values of the soil at the ditches averaged 5.93, as compared to 5.49 midway between the ditches. It appears that changes in the pH of the soil have not been sufficient to account for certain changes in the types of vegetation growing thereon. The water-requirement of the plant seems to be the detg. factor. K. D. Jacob

A quantitative study of true-prairie vegetation after three years of extreme drought. J. H. Robertson. *Ecol. Monographs* 9, 431–92(1939).—In a study of Nebraska prairies, there was no consistent relationship between any kind of alterne and the chloride or carbonate content or the pH of the underlying soil. K. D. Jacob

Growth of millet in quartz sand and in sand-soil mixtures. P. L. Gile. *J. Agr. Research* 59, 619–33(1939).—In 66 cases involving 46 soil samples, millet yielded 56% more on an av. in sand-soil mixts. contg. 1% of soil colloids than in pure quartz sand. Wheat in 4 comparisons gave about the same yield in both media The beneficial effect of soil admixts. on the yield of millet did not increase as the quantity of soil added was increased above that supplying 1% of soil colloids. The beneficial effect of soil admixts. did not seem to be due to supplying the trace elements Cu, Mn, Zn, B or F. Small quantities of peat, activated charcoal, Fe gel and freshly pptd. silica gel, in mixt. with quartz sand, produced an increase in yield and a modification in root growth, similar to those produced by soil. When a physiologically acid fertilizer is used, an injurious acidity may be developed in sand cultures in films contiguous to the roots. In sand-soil mixts. the films are doubtless less acid owing to the buffering effect of soil and the yield is consequently greater. Sand-soil mixts. should likewise yield more than pure sand when a physiologically neutral fertilizer is used owing to the effect of soil colloids in maintaining the availability of Fe. W. H. Ross

Fertilizers in relation to incidence of wilt as affecting a resistant and a susceptible variety [of cotton]. James B. Dick. *Proc. Assoc. Southern Agr. Workers* 40, 68 (1939).—The incidence of wilt was greatest, with correspondingly lower yield, when no K was applied. Increasing amts. of K lowered the incidence of wilt, but excessive amts. (600 lb. of 6–8–16 fertilizer per acre) greatly reduced yields in the resistant variety of cotton, while not appreciably reducing the yield in the susceptible variety. Application of N and K alone and in certain combinations effectively reduced wilt and increased yields. There was a differential response of the varieties used to fertilizer under conditions of severe wilt. The use of phosphate materially increased the incidence of wilt, particularly in the absence of adequate amts. of N and K; even when the latter were present the increase in wilt largely nullified the beneficial effects of K on yield. K. D. Jacob

Relation of unbalanced fertilization to the fusarium wilt of cotton. V. H. Young and W. H. Tharp. *Proc. Assoc. Southern Agr. Workers* 40, 190(1939).—Cotton that received high applications of K showed significantly less wilt than did cotton receiving low K and high P applications. Applications of unbalanced fertilizers, high in P but lacking in K, gave significant increases in wilt. K. D. Jacob

The effects of nitrogen source, nitrogen level and relative acidity on fusarium wilt of cotton. W. H Tharp and C. H. Wadleigh. *Proc. Assoc. Southern Agr Workers* 40, 190–1(1939).—Greenhouse sand-nutrient expts. were used to study the effects of variations in level of nitrate and ammonia N (20 and 100 p. p. m.) and variations in pH of the solns. (4, 6 and 8). A highly significant increase in wilt severity was assocd. with increase in N level and a significantly greater severity with the ammonia source. The variance of wilt severity resultant from change in pH was not consistently significant as a main effect, but susceptible plants supplied with the high nitrate soln. at pH 8 were less severely diseased than at either pH 6 or 4, while susceptible plants supplied with high ammonia solns. at pH 8 were more severely diseased than at either pH 6 or 4. K. D. Jacob

Loss of biologically fixed nitrogen from soils and its bearing on crop production. T. R. Bhaskaran and S. C. Pillai. *Science* 90, 595–6(1939).—When sugars (as molasses) are added to soils, the fixation of N is almost immediately followed by loss. Both processes proceed simultaneously till about 3 weeks, when the period of max. fixation is reached. The loss continues steadily even after this period so that, within the following 3–4 weeks, more than 60% of the fixed N disappears. In the presence of rice straw the loss is prevented. Felix Saunders

Urea as a source of nitrogen for potatoes in the Hastings area. R. V. Allison. *Am. Fertilizer* 92, No. 2, 8–9 (1940).—About 50% of the N in a mixed fertilizer for potatoes may be derived from urea instead of from natural org. sources without appreciably affecting the yield when the remainder is supplied by a combination of $NaNO_3$ and $(NH_4)_2SO_4$. The use of natural org. materials as 20% of the N source when the balance of this element is supplied by a mixt. of equal parts of urea and $(NH_4)_2SO_4$ did not affect the yield of tubers as compared either with the check treatment or the all-urea mixts. No stimulation in growth of vine or consistent increase in yield of tubers could be attributed to the use of a mineral supplement consisting of Mn, Zn and B. W. H. Ross

Effects of nitrogen, phosphorus and potassium nutrition on the fusarium wilt of cotton. W. H. Tharp and C. H. Wadleigh. *Proc. Assoc. Southern Agr. Workers* 40, 191 (1939).—Increase of N (4–100 p. p. m.) and P (0.1–30 p. p. m.) levels was assocd. with significant increases in wilt severity, while increase in the K level (2–40 p. p. m.) was accompanied by a significant reduction in severity, in plants grown in sand-nutrient cultures. The effect of many of the nutrient combinations was not the same for all 3 varieties of cotton tested. The disease severity in resistant and susceptible varieties was nearly proportionally affected by the treatment, while severity in the tolerant cotton was, in many treatments, affected disproportionally with the other 2 varieties. Similarly, the disease severity assocd. with variations in level of 1 element was not always proportionally the same at all variations in level of the other 2 elements. K. D. J.

The effects of nitrogen fertilizers upon the growth of spruce trees in forest nurseries. Antonin Němec.

Bodenkunde u. Pflanzenernähr. **16**, 98–112(1939).—The N requirement of spruce seedlings and transplants in forest nurseries is relatively the most important; although the removal of N from the soil is only at the rate of about 6 lb. N/acre the first yr. and 23 lb. the second yr., the later requirements of transplants in nursery beds are comparable to those of crops like wheat, around 70 lb. In tests of Chilean $NaNO_3$, $Ca(NO_3)_2$ and $(NH_4)_2SO_4$ at rates of 0.9 kg. N/100 sq. m. bed, applied half 3 weeks before planting and half at the peak of the growing season, and at 1/3 that rate the next yr., it was found that soil pH and fertility and C/N of the soil are important factors in growth response and tree losses following N fertilization. The physiol. acid NH_4 sulfate is best on soils not more acid than pH 5, the physiol. alk. nitrates on soils more acid. Besides unsatisfactory growth, losses of trees were excessive with N fertilizers unsuited to the soil; applications of all these fertilizers less than 3 weeks before planting caused losses of trees, which were less with suitable fertilizers. In general, N fertilizers were ineffective on soils with low C/N, except when total N was low. Six references. C. J. Schollenberger

Chemistry and growth of the cotton plant as affected by sorghum residues and nitrogen supplements. J. E. Adams, L. E. Hessler and D. R. Ergle. *Proc. Assoc. Southern Agr. Workers* **40**, 30(1939).—Progressively delayed and suppressed growth and yields of cotton plants were observed following the turning under of sorghum residues during Sept., Oct. and Jan. on Houston black clay soil. Growth and yields were restored by the application of 60 lb. N per acre, as $(NH_4)_2SO_4$. The bark of the roots of stunted plants was increasingly deficient in dialyzable N, both anode and cathode, as the date of turning under the residues was delayed. The carbohydrate components were not affected markedly. The proportion of total N to total P in the root stele was smaller for the last 2 dates than for the early date of turning. Supplemental N restored the dialyzable N of the bark to or above the level for roots from soils subjected to continuous growth of cotton; the proportion of total N to total P in the root stele was increased as a result of increase in the concn. of N and decrease in the concn. of P. K. D. Jacob

The action of bionitrified peat on plant growth and nitrogen enrichment. I. A. Makrinov. *Priroda* **26**, No 8, 51–7(1937); *Chem. Zentr.* **1938**, I, 4368–9; cf. *C. A.* **33**, 8881⁶.—Bionitrified peat, even in small doses (3% on the basis of loam used), is as satisfactory as saltpeter as a source of N. It increases the total N in the plant. Because of its high content in *Azotobacter* and nitrifying organisms it can be used instead of an inoculation of the soil. M. G. Moore

Water-culture studies with apple trees. II. The absorption of nitrogen and potassium by Cox's Orange Pippin on Malling rootstocks Nos. 9 and 12. H. L. Pearse. *J. Pomology Hort. Sci.* **17**, 344–61(1940); cf. *East Malling Research Sta., Ann. Rept.* **1936**, 131(1937).—Trees on No. 9 rootstock absorbed more H_2O per unit increase in fresh wt. than trees on No. 12. There was little qual. difference in the course of N and K absorption for the 2 types. Trees on No. 12 absorbed considerably more K per unit wt. of tree in the early part of the growing season than those on No. 9. While the trees on No. 12 absorbed nearly one-third as much again of both N and K during the course of the expt., the ratio of total growth made to the amt. of each of these nutrients absorbed did not differ significantly for the trees on the 2 rootstocks. Thirty references. John O. Hardesty

The sphere of activity of boron. Friedrich Herzinger. *Bodenkunde u. Pflanzenernähr.* **16**, 141–68(1940).—Boric acid added at rates of 0.27–27 lb./acre to plots of 1 sq. m. in a field of gravelly soil seeded to red clover had a striking optimum effect upon growth at 0.91 lb./acre; 0.45 lb. had slight effect and 6.3 lb. was distinctly toxic. *Sonchus oleraceus* growing with the clover showed similar responses. Germination expts. with seeds of *Sonchus* and *Crepis biennis* in dishes showed strong stimulation and no harmful aftereffects with 10^{-6} *M*, but toxicity was evident with 5×10^{-5} *M* H_3BO_3. In expts. with potato tubers cut into sections and poisoned with quinine cacodylate to blacken in simulation of heart-rot, 10^{-4}–10^{-6} *M* H_3BO_3 repressed the activity of tyrosinase and prevented melanin formation; at these concns., H_3BO_3 limits oxidation. Expts. with beets led to similar conclusions; incidentally, it was noted that *Phoma betae*, usually assocd. with heart-rot of beets, can grow in 0.1 *M* H_3BO_3. Expts. on reduction of methylene blue by pieces of potato indicated that 5×10^{-3}–10^{-6} *M* H_3BO_3 promotes the reducing action, with the optimum concn. in the region 10^{-4}–10^{-5} *M*. H_3BO_3 appears to have no action upon catalase, at least sections of potato treated up to 24 hrs. with 0.5 *M* H_3BO_3 showed practically no diminution in activity toward H_2O_2. These expts. continued with several varieties of potatoes for 1 yr. indicated a steady increase in catalase contents with age of tubers and lack of significant action of H_3BO_3 in all cases. Expts. with algae indicated that 1.6×10^{-4}–2.5×10^{-3} *M* H_3BO_3 stimulates filamentous green forms especially, but 2.5×10^{-5} *M* is toxic to some blue-green forms and diatoms; in these expts., toxicity was greatest in presence of a sandy soil, and was reduced by calcareous and peat soils. In presence of peat, one alga grew well in 0.001 *M* H_3BO_3. The growth of *Azotobacter chroococcum* in soil + culture soln. at pH 6.8 was noticeably better with 10^{-5} *M* and reached an optimum at 5×10^{-6} *M* H_3BO_3; the optimum for *Clostridium pasteurianum* and for nitrifiers was in the same region. Nitrifiers were still noticeably active with 0.01 *M*. H_3BO_3 is active toward flowering plants and many groups of soil microorganisms, and the concn. of greatest activity varies widely with species. Fourteen references. C. J. Schollenberger

The aftereffects of fertilization with boron. W. Schropp and B. Arenz. *Bodenkunde u. Pflanzenernähr.* **16**, 205–9(1940).—Sand cultures used the previous yr. for an expt. with beets (N-P-K fertilized with addn. of $MgSO_4$, Duggar's Fe mixt. and B equiv. to 8.1 lb. borax/acre) were again given N-P-K only and seeded to a variety of crops to det. the effects of residual B. In general, the latter were apparent only in yields, which were barely significantly increased with rye, barley, oats, vetch and soybeans, practically unchanged with field beans and rape, and barely significantly decreased with peas and hemp. Barley eared 2 days earlier and the grain:straw ratio of all the cereals was considerably improved in the crops grown on B-treated sand, as compared with similar sand not previously receiving B. The increase in dry-matter production by soybeans was also notable. C. J. S.

Oregon beets and celery need boron. A. G. B. Bouquet. *Better Crops with Plant Food* **24**, No. 1, 15–18, 33(1940).—The use of B on Oregon soils prevented the occurrence of beet canker and celery crack. Addns. of 10-30 lb. of borax per acre were sufficient. Liming increased canker or decreased the B availability. J. R. Adams

Manganese deficiency for citrus in California. E. R. Parker, H. D. Chapman and R. W. Southwick. *Science* **91**, 169–70(1940).—Spraying or injection of lemon trees with Mn salts resulted in greening of the leaves within 15 days. Felix Saunders

Effect of alkali salts on plant growth. J. L. Doughty and A. E. Stalwick. *Sci. Agr.* **20**, 272–6(1940).—The effects of several concns. of H_2O-sol. salts on the growth of wheat, oats and alfalfa are described. Six soils contg. 0.157–1.096% H_2O-sol. solids were used. There was a gradual loss in crop yield with increased salt concn. Approx. 0.4% sol. salts was the upper limit of fair crop growth. At a concn. of 1.096% of sol. salts, there was a reduction in crop yield of 33–77%. Alfalfa was more resistant than either oats or wheat. C. R. Fellers

The response of vetch and cotton to sodium. W. B. Andrews and Russell Coleman. *Proc. Assoc. Southern Agr. Workers* **40**, 61(1939).—The addn. of NaCl equiv. to 8% K_2O to 600 lb. per acre of 6–8–0 fertilizer increased the yield of seed cotton 195 lb. per acre, as compared to an increase of 93 lb. with half NaCl and half KCl and 69 lb. with all KCl. On a soil on which cotton gave no re-

sponse to K, Ca, lime, dolomite or Na, vetch gave an excellent response to $NaHCO_3$, Ca, lime and dolomite but not to K_2SO_4. Na doubled the yield of vetch where no response to K_2SO_4 was given. K. D. Jacob

Potash for cotton. N. J. Volk. *Proc. Assoc. Southern Agr. Workers* **40**, 32(1939).—The leaching of applied K to depths below the feeding zone of cotton is apparently a factor of importance in the more sandy soils of Alabama. The percentages of applied K that have been leached below the feeding zone during the last 9 yrs. at the Wiregrass Substation (Norfolk fine sandy loam), Sand Mountain Substation (Hartsells fine sandy loam) and the Tennessee Valley Substation (Decatur clay) are approx. 25, 15 and 7, resp. K. D. Jacob

The effect of low concentration of selenium upon the growth of grain. Geo. W. Stanford and Oscar E. Olson. *Proc. S. Dakota Acad. Sci.* **19**, 25–31(1939).—Relative growth values and comparative dry wt. of tops and roots were used as criteria. The concn. of Se in culture media was 0.001–0.05 p. p. m. Se stimulates growth of wheat and root elongation. The leaves of corn receiving Se increase in length less rapidly than those of controls. The wt. of the roots indicated stimulation by Se. With oats only an increase in the rate of change of height was found. Sorghum apparently is stimulated to some extent. Walter H. Seegers

Experiments with mixtures of Rhenania phosphate and ammonium sulfate. Werner Selke. *Bodenkunde u. Pflanzenernähr.* **16**, 112–28(1939).—The invariable correctness of the old opinion that fertilizers should not contain both $CaCO_3$ and an NH_4 salt, because of danger of loss of NH_3, is in doubt, since several com. mixts. of that kind are on the German market (*Kalkammonsalpeter* and *Kalkammoniak*), and experience has shown that their N content is effective; this indicates no losses in practice. Rhenania is a silicophosphate giving a strongly alk. suspension in H_2O; lab. expts. show that from mixts. with $(NH_4)_2SO_4$ and 10–25% H_2O, about 5% of the total N is readily removed by aeration. Basic slag contains more active CaO, around 31% as compared with 18% in Rhenania, and mixts. of $(NH_4)_2SO_4$ therewith lose NH_3 in about the same proportion. Extensive pot and field expts. with these and similar mixts. indicated that they can be made a day or so in advance of use, and if promptly covered with soil after application the N is fully effective, but if left on the surface uncovered, slight moistening by dew can cause considerable losses. C. J. Schollenberger

An example of correlation of soil type, manure requirement and the composition of the juice in sugar cane. J. Brink and T. H. van den Honert. *Sugar News* **21**, 53–6(1940); cf. *C. A.* **27**, 1694.—Relatively rich silty soil gave a high production of cane with low sucrose content. Soils fertilized with N and P gave increased cane production, increased N and P contents and decreased sugar content of the juices. W. W. Binkley

Nutrient solutions for sugar beets in sand and water cultures. F. Ya. Ukradyga and A. Oleksiyuk. *Compt. rend. acad. sci. U. R. S. S.* **17**, 491–4(1937); *Chem. Zentr.* 1938, I, 4223.—A new nutrient soln. especially suited to the requirements of sugar beets contains the following wts. in g. of the elements per 16 kg. of sand: N 3.39, P 0.85, K 4.15, Na 1.35, Ca 10 and Mg 0.76. M. G. Moore

(Lime and) beet/leaf ratio in sugar beets. Berkner. *Zuckerrübenbau* **21**, 139–51(1939).—Application of CaO to an acid soil reduced the ratio of leaves to roots from 1:1.328 to 1:10.96; the abs. yield of beets rose 12.6% and the abs. yield of leaves fell 22.1%. Sugar percentage of the beets was not affected. Excess of N in the soil raises the proportion of leaves; kainite is more favorable to leaf production than K_2SO_4. Varietal differences in leaf/root ratio are fairly const. whatever the circumstances under which the varieties are compared. O. W. W.

The effects of a deficiency of certain essential elements in the development and yield of carrots, onions and radishes grown in sand cultures under glass. R. M. Woodman. *J. Pomology Hort. Sci.* **17**, 297–307(1940); cf. *C. A.* **33**, 9520⁷.—Deficiency symptoms with respect to N, P, K, Ca, Mg, Fe, S and Na are described and quant. data as to yields and wt. ratios of the different parts of the plants are tabulated and statistically examd. Lack of K produced a tendency to scorch and wilt of portions of the tops of plants. Lack of N resulted in onion tops of a very pale-green color, and in a characteristic outlining in red of the cotyledons of the radish plant. With the solns. used and under the conditions of the expts., the deficiency of N and P greatly decreased the yields. The reduction in yields with solns. contg. only small amts. of K, Ca and Mg, however, were much smaller. J. O. H.

Potato research at Cornell University. Ora Smith *Am. Potato J.* **17**, 27–37(1940).—*Soil reaction and green-manure expts.* Total yields of potatoes were lower in plots of high pH than in the more acid soils and yields of scabby potatoes were lower at both low and high pH values than at intermediate values. At every range of reaction, yields were much higher following green-manure crops than those following potatoes. Yields of nonscabby tubers were higher at each pH value following green manure than following potatoes, whereas the percentage of scabby tubers at each pH value following green manure was lower than that following potatoes. In general, the pH of the soil in which the green manure was incorporated was lower in July, 1939 than in soil that had grown potatoes every yr. *Controlling dormancy in the potato.* Tubers were immersed in 0.01% solns. of growth substances for 43 hrs. and then planted in the greenhouse at 70–80°F., with subsequent transplanting to the field. Indoleacetic acid treatment had practically no inhibiting effect on growth of the plants in the greenhouse, whereas tubers treated with naphthaleneacetic acid remained dormant about 6 weeks at 70°F. The largest yields of potatoes were obtained from tubers treated with indoleacetic acid and the smallest from those treated with tap water. Growth substances penetrated cut tubers more readily than whole tubers and had a greater inhibiting effect in the 1st case; the results were not affected by treating the tubers with wax. The subsequent rooting of potato sprouts was considerably increased by immersing the cut ends for 18 hrs. in 0.01% solns. of either indoleacetic or naphthaleneacetic acid. *Potato cooking quality.* Potatoes of a more mealy texture were produced in a soil of pH 7.88 than in soils of lower pH. More blackening of tubers during cooking was observed in potatoes grown in soils of pH 4.92 and 6.36 than at pH 7.88. K. D. J.

Temperature and other factors in relation to germination of potato sets and tubers. H. B. Cordner. *Proc. Assoc. Southern Agr. Workers* **40**, 151–2(1939).—Ordinary fungicides and disinfectants were ineffective in preventing decay of potato tubers planted in soil at temps. above 90°F. Tubers or sets under the stimulating influence of ethylene chlorohydrin treatment decayed more when planted at high temps. than did untreated tubers and sets. Also, storage of tubers at high temps. (90–95°F.) following harvest and especially after treatment with ethylene chlorohydrin lowered the seed value considerably. Any treatments or conditions which tend to minimize respiration and to increase the access of O to the internal tissues of the tuber or set should be helpful in preventing seed-piece breakdown. K. D. Jacob

Raspberry nutrition. IV. Can the Cuthbert raspberry be saved in British Columbia? G. Howell Harris. *Sci. Agr.* **20**, 344–54(1940); cf. *C. A.* **32**, 2270⁸,⁹.—In many cases decline has been due to soil deficiencies of N, P, K and sulfate. The raspberry responds to the luxury feeding of P in particular. Foliar diagnosis readily detects deficiencies in N, P, K and sulfate in soils. The limited water supplies of many of the upland soils limit raspberry growth. The addn. of peat to these soils improves the water-holding capacity and, indirectly, raspberry nutrition. The addn. of lime was either of no benefit or even injurious. C. R. Fellers

Sweet lupine cultivation. E. Miège. *Compt. rend. acad. agr. France* **25**, 1031–4(1939).—Data are given for the agricultural characteristics and chem. compn. of lupines from Morocco and the alkaloid content of their grain, of the plants at flowering and of the plants 3 months

after drying. These lupines can be considered sweet and inoffensive. The starch value of the green plants is equal to the starch values of lucerne and clover and their grain is similar to those of the cereals. J. R. Adams

Results with the transplanting solution. Jackson B. Hester. *Am. Fertilizer* **91**, No. 13, 11–13(1939).—The addn. of 4–6 lb. of a nutrient mixt. consisting of 4 parts of superphosphate, 1 part of Calnitro and 1 part of KNO_3 to 50 gal. of the transplanting water not only increases the yield of tomatoes, but also results in an earlier harvesting time. W. H. Ross

Fertilization of apple and prune orchards in Idaho. Lowell R. Tucker. *Idaho Agr. Expt. Sta., Bull.* **226**, 2–12(1938).—A 5-yr. expt. in S. Idaho showed that applications of $(NH_4)_2SO_4$ at the rate of 1 lb. per tree increased yields of Italian prunes about 52% in 1 case and 18% in another locality. There was little or no effect on the quality of either apples or prunes. Neither P nor K gave yield increases with these fruits. C. R. F.

Effect of moisture, fertility and fertilizer placement on root rot of canning peas in Wisconsin. J. C. Walker and F. L. Musbach. *J. Agr. Research* **59**, 579–90(1939). Readily available nutrients applied at rates of 200–300 lb. per acre in the furrow with the seed increase the resistance of canning peas to root rot. Much greater increases in yield and reduction of root rot were secured when 2% of readily available N was included in the fertilizer than when it was omitted. W. H. Ross

The fertilizer action of bone meal and basic slag. L. Gisiger. *Bodenkunde u. Pflanzenernahr.* **16**, 210–29 (1940).—From a review of the literature, G. concludes that the P_2O_5 of bone meal is most effective on acid soils, and its availability is depressed by $CaCO_3$; basic slag is an effective P_2O_5 carrier on all soils. His lab. expts. on the soly. of P_2O_5 in these fertilizers in citric acid solns from 2% down, final pH 3.1–6.3, and that sol. by repeated extn. with CO_2-satd. and partially satd. H_2O showed no correlation with the accepted conditions for max. activity of these fertilizers. However, when the repeated extn. with $H_2O + CO_2$ was applied to mixts. of the fertilizers and pptd. $CaCO_3$ or gound limestone, total P_2O_5 extd. from bonemeal was but 0.1–0.2 that from basic slag and similar differences were shown in mixts. with calcareous soils; from similar mixts. with strongly acid soils, without $CaCO_3$, similar amts. of P_2O_5 were extd. from both carriers. These results, bringing lab. tests into harmony with field indications, are explained on the basis of equil. pH and Ca^{++} concns. and their effects on the soly. of Ca phosphates. Seven references. C. J. S.

Artificial manure compared with horse manure for biological heating of hot beds. E. Mantel. *Bodenkunde u. Pflanzenernahr.* **16**, 59–89(1939). –Practical scale expts. with hot beds heated by fresh horse manure and artificial manure, wheat straw presoaked for 24 hrs., then mixed with 0.7% its dry wt. of N as $CaCN_2$ or $CO(NH_2)_2$, etc., and chem. and phys. tests during the course of the work, are described. Conclusions: the hot beds themselves are the most suitable containers for the artificial manure in the earlier stages of fermentation; even in midwinter no other containers are necessary. Heaping in the open will not serve the purpose. The onset of heating is slower with $CaCN_2$ because some $(H_2CN_2)_2$ is formed and limits bacterial development. With urea, heating begins quickly and is more vigorous, so that this is the better N carrier for use in midwinter, but artificial manures prepd. with either heat satisfactorily when trodden down in the beds at the proper stage of fermentation. It has been the practice to allow manure to heat to the max. before treading down, but these straw mixts. should be allowed to heat to 15–20° only for best results, otherwise the heating will be of short duration; this is the explanation of the unsatisfactory results previously reported (*C. A.* **33**, 2270[3,6]). Measurements of CO_2 in the soil air by a technique described indicated up to 9.6%, and a corresponding max. of 0.36% in the air about the plants, with horse manure as standard packing; values with the straw mixts. were about ⅔ as high. Yields of lettuce and cucumbers were less in beds with the straw mixts., attributed to insufficient P_2O_5 and K_2O addns. to equalize with horse manure, but otherwise growth was similar. Analyses of the spent packing showed that the straw mixts. invariably lost more org. substances in fermentation than the horse manure and contained similar amts. of N, around 2% in dry sample, but only about 0.4% P_2O_5 and 0.9% K_2O, compared with 1.5 and 3.8%, resp., in spent horse manure. All the spent materials had C/N near 20, corresponding to good farm manure, except 26 and 22 for 2 lots prepd. with $CaCO_3$ + urea as the N carrier, which heated less vigorously. Humus insol. in AcBr was rather variable, 18–24%, but there were no significant differences. The satisfactory and uniform course of heating with straw-urea mixts. makes them a better standard material than the variable horse manure for exptl. work; the practical utility of the former as substitutes for horse manure is merely a matter of comparative costs. Twenty references. C. J. Schollenberger

Greenhouse fertilizer studies of celery. L. F. Ounsworth. *Sci. Agr.* **20**, 329–43(1940).— Sand cultures indicated that the equiv. of 1 ton per acre of a 4-8-16 fertilizer mixt. gave best results. Root systems were affected by the deficiencies of N, P and K. K deficiency produced poorly developed root systems with few rootlets. P was the limiting factor on muck soil, while addns. of N and K to mineral soils adversely affected growth. By increasing P addns beyond certain limits, growth was decreased. In some of the expts. K did not increase growth or quality, but it had no harmful effect except in the mineral soil plots. There must be an optimum balance of the elements for optimum growth. C. R. Fellers

Fertilizing value of beet greens. J. Garola. *Compt rend. acad. agr. France* **25**, 1083–8(1939), cf. *C. A.* **33**, 8893[7].—The yield of forage beet greens per hectare contains 31.5–67.0 kg. N, 5.8–16.4 kg. P_2O_5 and 30.6–105.0 kg. K_2O. There is considerable fluctuation in the compn. and quantity of greens and these are greatly influenced by nitrogenous fertilizers. Before incorporating beet greens in the soil their compn. should be detd. In respect to N availability, beet leaves and collars are comparable to manure. The use of beet greens is of economic importance in the cultivation of wheat, principally in respect to N and K_2O. J. R. Adams

Commercial fertilizers. H. R. Kraybill. *Purdue* (Ind.) *Agr. Expt. Sta., Circ.* **250**, 80 pp.(1939). In 1938 in Ind. an av. of 1 inspection sample was drawn from each 156 tons of fertilizer. Of these samples 1396 were equal to or above the guarantee in value, 97 were within 10% of the guaranteed value and 8 were 10% or more below the guarantees. The av. analysis of all fertilizers sold was 1.9% N, 12.9% H_2O-sol. and reverted P_2O_5 and 9.0% H_2O-sol. K_2O. C. R. Fellers

Methods for the continuous production of superphosphates. E. N. Ginzburg. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 26–30(1939).—App. is described. H. M. Leicester

Methods for determining magnesium and calcium in fertilizers. John B. Smith and E. J. Deszyck. *Am. Fertilizer* **91**, No. 13, 5–9, 22, 24(1939); cf. *C. A.* **33**, 7018[8].—Data from various sources showing the rate of decompn. of dolomite in av. soils have been summarized, and an acid NH_4 citrate soln. is described that gives results that correlate in general with the av. rate of decompn. of dolomite in soil. The Bartlett-Tobey (*J. Assoc. Official Agr. Chem.* **20**, 252–63(1937)) method for Mg is more rapid than the official method and is sufficiently accurate for control work. The gravimetric modification of this method gives results that are slightly higher and rather more consistent with the official method than the acidimetric titration procedure. Ca should be detd. simultaneously with Mg and this can be done more easily by using the oxalate sepn. of the Bartlett-Tobey method than by sepn. of $CaSO_4$ in alc. W. H. Ross

Compilation of experimental data on cotton fertilizers. E. E. Gross. *Miss. Agr. Expt. Sta., Bull.* **321**, 94 pp. (1938). C. R. Fellers

Molasses as fertilizer and soil reclaimant in agriculture. B. T. Narayanan. *Proc. Soc. Biol. Chem. India* **2**, 31–2

87). Molasses applied to alk. tracts of land has effected great improvement, but not less than 10 weeks elapse between treatment and planting. Unconfined expts. on N-fixing and fertilizer effects reveal practical difficulties of transport and application.
B. C. P. A.

Magnesium oxide as an ingredient of mixed fertilizers. W. Whittaker, L. F. Rader, Jr., and K. V. Zahn. *Am. Fertilizer* **91**, No. 12, 5–8, 24, 26(1939).—The greater part of the Mg in active MgO becomes water-sol. when included in fertilizer mixts. of the ordinary type. Active MgO can be mixed with superphosphate at rates up to 1 lb. per ton without serious reversion if the storage temp. is kept below 60°. The upper limit for ammoniated superphosphate mixts. under the same conditions is about 2 lb. per ton. Elevated storage temps. greatly increase the amt. of P_2O_5 reversion in mixts. contg. MgO. Loss of NH_3 begins to occur from an ammoniated superphosphate contg. 80–100 lb. of MgO per ton and from an ammoniated 6–8–6 mixt. contg. 40–80 lb. of MgO per ton. In NH₄ phosphate mixts. contg. MgO and an NH_4 salt, a small proportion of the water-sol. N changes to the insol. form. The addn. of MgO to a mixed fertilizer tends to dry out and condition the mixt. MgO may be used for complete neutralization of physiol. acidity in mixts. that do not have the equiv. acidity in excess of 100 lb. of $CaCO_3$.
W. H. Ross

Entomological review, 1936. E. P. Jones. *Brit. S. Africa Co. Pub.* No. **6**, 3–18(1937); *Rev. Applied Entomol.* **A**, 14–15(1939); cf. *C. A.* **31**, 7582².—Damage by *Heliothrips aurantii* Faure to the 1936 crop of citrus on estates in Southern Rhodesia was considered to be due in part to the fact that the lime-S spray used against the pest contained only 25 instead of 31–3% polysulfides. Fumigation with HCN from Cyanofumers against the red scale, *Aonidiella aurantii* Mask., caused severe scorching and pitting of the fruit in parts of some groves. This damage appeared to be correlated with areas of high temp. and humidity. Attempts to control larvae of *Prothis armigera* Hubn. (*obsoleta* Fabr.) with various dusts and sprays are described, and it is concluded that no efficient insecticide has yet been found against this noctuid on citrus.
Edwin J. Seiferle

Tests of insecticides. P. A. van der Laan. *Mededeel. v. het Proefsta.* [2], No. **100**, 20–5(1938).—In comparative field tests in Sumatra in 1937, derris dusts contg. 1.5 and 3% rotenone were inferior to 5% Pb arsenate dust in protecting tobacco against lepidopterous larvae. In other tests no distinct difference in injury by the larvae was observed when tobacco was dusted with 5% $BaSiF_6$ or sprayed or dusted with 5% Pb arsenate. In expts. against the larvae in seed beds a derris dust mixt. (3% rotenone) gave better results than a spray of derris powder mixed with water to a 1:10,000 rotenone content, but was less effective than a 1.5% Pb arsenate spray. In lab. expts. *Spodoptera litura* F. was almost insensitive to derris dust but *Heliothis assulta* Gn. was only slightly affected. 1% rotenone-contg. dust gave 80% mortality of *Plusia nata* F. in 2 days. Capsid bugs were very sensitive and crickets were not. A dust contg. 5% phenothiazine proved ineffective against *P. signata*.
E. J. S.

Composition and length of action of rotenone powders. Feytaud and P. de Lapparent. *Compt. rend. acad. agr. France* **25**, 1039–44(1939).—The efficiency against Syphora larvae of good mixts. contg. 15% of cubé or derris root is practically as great as the efficiency of pure cubé powder and there is no advantage in exceeding this figure. $CaCO_3$, carbonated talc, S, plaster and even kaolin are better carriers of the powder than silica, bentonite and especially CaO. Rotenone powder, pure or mixed with a carrier, retains its insecticidal power almost fully for more than a yr. not only in a closed container but even after exposure to air, light, moisture and inclement weather.
J. R. Adams

Cyclohexylamine, an attractant for Lathyrophthalmus arvorum Fabr. Donald Starr and Kam Hu Lau. *Proc. Hawaiian Entomol. Soc.* **10**, No. 1, 61(1938).—Lures contg. cyclohexylamine were found to be attractive to *Lathyrophthalmus arvorum* Fabr. and repellant to the Mediterranean fruit fly (*Ceratitis capitata* Wied). The lures contained casein 9.4, NaOH 5.0, slaked lime 12.9 and cyclohexylamine 3.7 g. per l.
J. R. Adams

Field experiments with a new contact poison against the nun moth (Lymantria monacha L.). Christoph Hofmann and Karl Dauberschmidt. *Forstwiss. Centr.* **61**, 605–16(1939). **A new contact dust medium (Nemotan) against nun and pine moths.** Christoph Hofmann. *Forstarchiv* **16**, 8–11(1940); cf. *C. A.* **33**, 2645³.—"Nemotan," or "2172," whose active ingredient is similar to that in "2152," showed in field tests against *Lymantria monacha* L. and *Bupalus piniarius* L. that it is as effective as dinitrocresol prepns. It has advantages over the latter in possessing no toxic properties toward warm-blooded animals and in not causing any appreciable burning of young shoots, needles or leaves of the trees. It should be applied at the rate of 70–80 kg./ha. "Nemotan" is somewhat slower in its action than the dinitrocresol product "Detal," but its effectiveness is more enduring.
C. K. Horner

Apple and pear fire blight. C. D. Sherbakoff and J. O. Andes. *Tenn. Agr. Expt. Sta., Circ.* **64**, 1–4(1939).—The spraying of apple and pear trees in full bloom with 1-3 50 Bordeaux mixt. gives sufficient reduction of blossom blight to assure a fruit crop. To control fire blight, trees should be sprayed twice preferably in the middle and late stage of bloom. In addn., infected areas should be pruned out and painted with a $Co(NO_3)_2$ soln. prepd. by mixing 2 oz. of glycerol, 4 oz. oil of wintergreen, 2 oz. AcOH and 1 quart of MeOH. To this soln. add 4 oz. of $Co(NO_3)_2$ crystals, stir until dissolved and keep in stoppered bottles. A $ZnCl_2$ soln. can also be used.
C. R. Fellers

The physiological effects of mineral oils on citrus. L. W. Ziegler. *Florida Entomologist* **22**, 21–30(1939).—Applications of high concns. (1.67%) of mineral oil (70 sec. viscosity, 83% unsulfonated residue) exert a direct effect on Valencia trees, which is most pronounced in the droppage of tree-ripe fruit and mature leaves owing to the greater penetration of oil because of their lowered surface tension. Drop of immature leaves and fruit is much smaller. The loss of large nos. of leaves following heavy applications of oil adversely affects the size of the immature fruit, except where the reduction of the crop is approx. proportional to the reduction in leaf area. The quantity of fruit borne in the succeeding crop is reduced and the subsequent flush of growth is accelerated. Killing of the wood is sometimes brought about either directly as a result of oil penetration or as a secondary effect should new growth fail to appear after drop of leaves. These adverse effects are brought about by applications of oil at periods of the yr. which are normally considered untimely for such applications.
K. D. Jacob

Commercial control of citrus scab in Florida. George D. Ruehle and W. L. Thompson. *Fla. Agr. Expt. Sta., Bull.* **337**, 47 pp.(1939); cf. *C. A.* **31**, 1544⁷.—Homemade Bordeaux mixt. made from pulverized $CuSO_4$ and superfine lime will give consistently good results in the control of citrus scab, *Sphaceloma fawcetti*. For ordinary infection a concn. of 3-3-100 is satisfactory; for severe infections, 6-6-100. Several of the com. Cu prepns. also gave good control. Lime-S soln., 4-100 with added wettable S, gave only partial control. Hg-oil emulsions were unreliable. In older trees infected with both scab and melanose 2 sprayings with Cu fungicides are necessary for effective control of both diseases.
C. R. Fellers

Mexican bean beetle in South Carolina. Franklin Sherman and J. N. Todd. *S. Carolina Agr. Expt. Sta., Bull.* **322**, 5–24(1939).—Rotenone gave the most promising results in combating the Mexican bean beetle. A suitable formula consists of 5% powd. derris or cubé 15 lb. and talc 85 lb. If used as a spray, the proper proportions can be obtained by using 1.75 lb. of 5% derris or cubé root in 50 gal. of water. While both Mg arsenate and cryolite give fair control of the beetle, they leave toxic residues of As and F on the vegetables and should not be applied after the pods have formed.
C. R. Fellers

Control of shade-tree borers. F. A. Fenton. *Okla. Agr. Expt. Sta., Circ.* **84**, 28 pp.(1939).—General. C. R. Fellers

Fruit pests and their control. P. O. Richter, W. D. Valleau and W. W. Magill. *Kentucky Agr. Expt. Sta., Bull.* **393**, 121–79(1939).—Formulas and methods of prepn. of spray and dust materials are given together with a description of common insect diseases and their control. C. R. Fellers

Spraying apples for the prevention of fruit set. Paul H. Shepard. *Missouri Agr. Expt. Sta., Circ.* **28**, 3–27 (1939).—Highest percentage of spur injury resulted from the use of cresylic acid and tar oils, particularly on Champion variety. The 5-year field trial shows that 0.5–2.0% cresylic acid or tar oil No. 1 at 3% was the most effective agent in the destruction of bloom. These agents prevent fruit set by killing the pedicels. C. R. Fellers

Dormant and delayed dormant sprays for the control of rosy apple aphids and scale insects. W. S. Hough. *Virginia Agr. Expt. Sta., Bull.* **322**, 3–31(1939); cf. *C. A.* **33**, 4733[1], 7474[8].—There were no consistent differences in insecticidal efficiency of the petroleum oils used so long as the viscosities were above 100 sec. Saybolt. A paraffin-base oil having a viscosity of 81–4 sec. Saybolt and a higher evapn. rate than heavier oils was usually the least effective of the oils used against San Jose and cherry scales. Dormant sprays contg. 3% of petroleum oil + 2.5% of tar oil were effective in controlling rosy apple aphids and San Jose, cherry and scurfy scales. Dinitro-*o*-cyclohexylphenol used alone at the rate of 7.5 8.0 oz. per 100 gal. dild. spray were less effective in controlling rosy apple aphids, San Jose and cherry scales. Mixts. of lauryl thiocyanate and petroleum oil were also effective insecticides, but at concns. of 0.2–0.8% the thiocyanate was caustic to fruit buds. Dinitro-*o*-cresol used at the rate of 2.5 lb. per 100 gal. in a 3.6% dormant spray oil was effective in controlling rosy apple aphids (*Anuraphis roseus* Baker). The most effective delayed dormant spray against the rosy aphids consisted of a mixt. of 3% oil + 0.4% tar oil. C. R. Fellers

Role of surface tension and contact angle in the performance of spray liquids. Walter Ebeling. *Hilgardia* **12**, 665–98(1939).—The static contact angle indicates the spreading and penetrating properties of the liquid after it has been deposited on the plant surface. The nature of the substratum had a marked influence on the contact angle liquid/solid. Various solutes were tested with reference to their effect in lowering the contact angle of water and oil on various solids. A reduction in surface tension and of the contact angle of the liquid may increase its penetrativity into capillary tubes on the inner surface of which it has a high contact angle, but reduces its penetrativity in tubes on the inner surface of which it has a very low or zero contact angle. The practical application of the principle is that by a reduction of surface tension the rate of penetration of aq. solns. into porous solids such as bark, on which solns. have a very low contact angle, may be decreased and their rate of penetration through waxy insect threads or bodies may be increased. C. R. Fellers

Experience with the pecan nut casebearer in Texas in 1938. C. B. Nickels and W. C. Pierce. *Texas Pecan Growers' Assoc., Proc. Ann. Meeting* **18**, 36–9(1938); cf. *C. A.* **32**, 2274[6].—Satisfactory control of the insect (*Acrobasis caryae* Grote) was obtained by a single spray application of Pb arsenate 6, Zn sulfate 2 lb. and summer oil 1 gal. per 100 gal. water, made on April 23–25. Control was somewhat less satisfactory with a single application of Pb arsenate 6 and Zn sulfate 2 lb. per 100 gal. water, with or without soybean flour 1 lb. The newly hatched larvae are susceptible to poisoning with arsenicals, but it is difficult to poison nearly full-grown larvae. K. D. Jacob

Results of three years' spraying with low-lime Bordeaux mixture for the control of pecan scab. John R. Cole and John R. Large. *Southeastern Pecan Growers' Assoc., Proc. Ann. Convention* **32**, 28, 30, 32–4(1938); cf. *C. A.* **33**, 302[1]. **Résumé of four years' spraying of Schley pecans with Bordeaux mixture to control the scab disease.** *Ibid.* **33**, 24, 26, 28, 30, 32, 34–5(1939).—A prepollination spray application of 4:1:100 Bordeaux mixt. followed by 3 applications of 6:2:100 mixt. at intervals of 3–4 weeks gives 85–95% control of scab caused by *Cladosporium effusum* (Wint.) Demaree. K. D. Jacob

Control of Cercospora leafspots of peanut with various dusts and sprays. Luther Shaw. *Proc. Assoc. Southern Agr. Workers* **40**, 181(1939).—In a 2-yr. test, 3 applications of S dust (approx. 16 lb./acre/application) made about July 25, Aug. 14 and Sept. 1 reduced the prevalence of leafspot lesions on peanut leaflets approx. 75%, reduced defoliation about 70% and increased the yield of peanuts 217–343 lb./acre. Three applications of 4:4:50 Bordeaux mixt. or Cuprocide 54 (1.5:50) also gave excellent control of leafspot and substantial increases in yields of peanuts and hay. Liquid lime-S (1:40) gave good control of the disease but injured the foliage. Pyrethrum dust had no fungicidal value. K. D. Jacob

Leafhopper and weed control [in cranberry bogs]. Charles S. Beckwith. *Am. Cranberry Growers' Assoc., Proc. Ann. Convention* **70**, 7–11(1939).—Kerosene sprayed at the rate of 400 gal./acre on grassy bogs in May killed 90% of the grass without affecting the cranberry vines. Applications of kerosene in June controlled red root but seriously injured the cranberry vines. There was evidence that fern growth can be controlled by spraying with $CuSO_4$ (20 lb. per 100 gal.) without injury to the vines. A soln. of NaCl (1 lb./gal.) sprayed on wild sweet potato vines when they were well up over the cranberry vine killed the vegetative portion of the weed without damaging the cranberries. Ca arsenite was toxic to cranberry vines as well as to poison ivy. K. D. Jacob

Bordeaux injury to cucumbers. A. G. Plakidas. *Proc. Assoc. Southern Agr. Workers* **40**, 181(1939).—In field tests, satisfactory control of downy mildew of cucumbers (*Pseudoperonospora cubensis*) was obtained with either 4-4-50 Bordeaux mixt. or Copper Spray 34; Copox dust was less effective. Bordeaux mixt. caused 3 types of severe injury: (1) severe stunting of vine growth, (2) marginal burning of the young leaves and (3) burning ("scorching") of the localized, irregular areas on the older leaves. In 3 replications, the plots sprayed with Copper Spray 34 gave 27.7, 31.6 and 93.4% higher yield of cucumbers than did those sprayed with Bordeaux mixt. K. D. Jacob

Weed control in tulip and narcissus bulbs. J. Hargrave and F. C. Thompson. *Agr. Inst. Exptl. Sta., Kirton, Rept. on Bulb Expts.* No. 6, 6–18(1939), cf. *C. A.* **34**, 2127[1].—Satisfactory control of weeds, without adverse effect on yield of tulip bulbs, was obtained by the application of $CaCN_2$ (5 cwt./acre) to the beds in January or some time before the foliage appeared above the ground. $NaClO_3$ (20 lb./acre applied as a wet spray) and late applications of $CaCN_2$ depressed the yield. Neither $NaClO_3$ nor $CaCN_2$ had a significant effect on the forcing qualities of the bulbs or the date of cropping. Expts. to det. the effect of $NaClO_3$ and $CaCN_2$ on the yield of narcissus bulbs gave inconclusive results, but applications of $CaCN_2$ (3–5 cwt./acre) hastened flowering. K. D. Jacob

The hot-water treatment injury of narcissus bulbs J. Wood. *Agr. Inst. Exptl. Sta., Kirton, Rept. on Bulb Expts.* No. 6, 48–58(1939); cf. *C. A.* **34**, 2128[3]. Susceptibility to injury was decreased by storing the bulbs at 80°F. for 4 weeks prior to subjecting them to hot-water treatment (110°F. for 3 hrs.). K. D. Jacob

Seed-treatment tests with cotton in 1938. D. C. Neal. *Proc. Assoc. Southern Agr. Workers* **40**, 187(1939).—Results of seed treatments with Ceresan, Improved Ceresan, Cuprocide and Barbak C, for control of anthracnose, *Rhizoctonia* and *Fusarium* spp., were inconclusive. K. D. Jacob

Treatment of cottonseed with organic mercury dust and sulfuric acid. George J. Harrison. *Proc. Assoc. Southern Agr. Workers* **40**, 191(1939).—Treatment of the seed with org. Hg dust aided materially in obtaining stands of cotton when temps. were unfavorable for germination, but no benefit resulted from delinting the seed with H_2SO_4.

Neither treatment gave significant increase in yields of cotton and, after seedling emergence was complete, neither gave any control over seedling diseases such as *Rhizoctonia*. K. D. Jacob

Seedling survival as affected by certain mercury, copper and zinc preparations not included in the regional cotton-seed treatment tests for 1938. S. G. Lehman. *Proc. Assoc. Southern Agr. Workers* **40**, 188(1939).—Significant increases in seedling survival were obtained by treating either 1- or 4-yr. old cottonseed with either Ceresan (2% Et Hg chloride), Sanoseed (2% ethanol Hg chloride) or Sterocide (4% Hg furfuramide dild. to 2% with talc). The best results were obtained with Ceresan. Ceresan gave approx. equal results with 1- and 4-yr. old seed, whereas Sanoseed and Sterocide gave larger increases with 1-yr. old seed. In other tests with AAZ Special ZnO, Cuprocide, Cu oxychloride and Cu_2O only the ZnO increased the seedling survival significantly. K. D. J.

Sterilization of lettuce seed. H. L. White. *Ann. Applied Biol.* **25**, 767-80(1938).—Treatment with $CuSO_4$ or CH_2O does not produce satisfactory sterilization without seed injury. Org. Hg compds. are highly toxic to the seed. Effective sterilization was obtained with aq. $CaOCl_2$ (2% Cl); germination was accelerated. B. C. P. A.

Seed and soil treatments for combating damping-off of tomatoes, eggplants and peppers. L. H. Person. *Proc. Assoc. Southern Agr. Workers* **40**, 180(1939).—Over a 4-yr. period Cu_2O was the most effective seed-treatment material for controlling damping-off of tomatoes and peppers, caused by *Rhizoctonia* and *Pythium*, principally the first. For eggplant, Cu_2O seed-treatment supplemented with a ZnO soil-treatment (20 g./sq. ft., applied at the time of seedling emergence) was the most effective treatment. Treatment of the soil with concd. CH_2O was effective if precautions were taken against recontamination. Results with CH_2O dusts applied to the soil at the rate of 1.5 oz./sq. ft. were inconsistent. In some tests, Semesan used as a seed treatment caused a marked reduction in germination. K. D. Jacob

The fungi that cause root rot and the possibilities of their control through soil treatment with chemicals. R. F. Poole. *Proc. Assoc. Southern Agr. Workers* **40**, 182(1939). —Changes in the soil pH offer very limited possibilities in the control of the most prevalent parasitic organisms in the soils of North Carolina. Wide changes in the soil reactions maintained over a period of 5 yrs. have been ineffective in bringing about controls by biol. means. Most of the soils in N. C. are sufficiently acid to inhibit the parasitism of *Thielaviopis basicola* and *Actinomyces scabies*. K. D. Jacob

Further studies on control of soil rot of sweet potatoes. L. H. Person. *Proc. Assoc. Southern Agr. Workers* **40**, 179-80(1939). Applications of 600-800 lb. S per acre lowered the pH of the soil from 5.8-6.0 to 4.8-5.0. In the sulfured plots growth of potatoes was apparently normal, while in the control plots the plants remained small, became chlorotic and many of them died. Yields in heavily infested soils were increased from almost nothing in the control plots to 75-115 crates of U. S. 1 and 2 grades, field run, in the sulfured plots. K. D. J.

Control of oat sickness by addition of chemicals to soil infected with Heterodera schachtii, Schmidt. E. E. Edwards. *Ann. Applied Biol.* **25**, 855-66(1938).—Among a no. of substances examd., $CaCN_2$ significantly improved growth of oats and lowered infestation by the nematode. Applied at the rate of 5 tons/acre, $CaCN_2$ completely protected oats from sickness over a 2-year period and eradicated the nematode from the soil. B. C. P. A.

Carbon dioxide evolution from certain soils in relation to black root-rot of flue-cured tobacco. J. A. Pinckard and Luben Bozovaisky. *Proc. Assoc. Southern Agr. Workers* **40**, 182(1939).—The evolution of CO_2 from Granville sandy loam and Cecil sandy loam was detd. on 600-g. samples adjusted to ²/₃ of their moisture-holding capacities and incubated in respiration chambers for various periods of time and at different temps. Detns. were made almost daily on samples following field transplanting of tobacco and until 2 months after harvest. *Thielaviopsis basicola* was a limiting factor of growth in the Cecil sandy loam (pH 6.2) but not in the Granville soil (pH 5.7). CO_2 production, per sample per day, ranged from 2 to 8 mg. Triplicate samples from around the roots of plants in field plots receiving 800 lb. of a 3-10-6 fertilizer mixt. and from adjacent unfertilized check plots showed little difference in 7 samplings made through the season. After harvest, 3 g. chopped Italian rye grass plants or tobacco plants, incorporated in the soil samples, showed practically complete decompn. in 30 days. The low yields of CO_2 in these soils indicate a min. total microbial population and a min. of decomposable org. matter regardless of the presence of *T. basicola*. K. D. Jacob

The selenium content of grasshoppers found feeding on seleniferous vegetation. Alvin L. Moxon. *Proc. S. Dakota Acad. Sci.* **19**, 69-70(1939).—There is a direct correlation between the Se content of the insects and the vegetation upon which they feed. As much as 20 p. p. m. was found in *Melanoplus bivittatus*. Se is therefore not considered an effective poison for these insects. Walter H. Seegers

Recovery of copper from grape leaves treated with fungicides. Ettore Garino-Canina. *Ricerca sci.* **10**, 1140(1939).—The Italian wine industry consumes annually 80,000 tons of imported $CuSO_4$. The dried leaves of vines sprayed 10 times with a 1% Bordeaux mixt. yield 18-20% ash contg. 3.1-3.9% Cu. The yield of dry leaves from 1 hectare is about 1300 kg. from which Cu equiv. to 30 kg. of $CuSO_4$ might be recovered. O. W. Willcox

A discussion of official methods for the determination of pyrethrins and rotenone. J. J. T. Graham. *Soap (Sanit. Products Sect.)* **16**, No. 2, 99, 101, 103(1940).—The Holaday modification (*C. A.* **32**, 3078[7]) of the Wilcoxon method (*C. A.* **30**, 8076[3]) has been officially adopted by the Assoc. of Official Agr. Chemists for pyrethrin I analyses of pyrethrum powders. None of the methods for pyrethrin II analyses is considered entirely reliable but the Seil method (*C. A.* **28**, 4531[1] and 6935[2]) is probably the best so far proposed. The Wilcoxon method has been tentatively adopted for analysis of oil exts. of pyrethrum. The Jones-Graham method for detg. rotenone in derris has been officially adopted. Aspects of the methods are discussed. Eight references. Henry H. Richardson

Soil disinfectant. N. V. Chemische Fabrieken en Handelmaatschappij voorheen firma Jan E. de Boer. Dutch 46,874, Oct. 16, 1939. Forty % formaldehyde 200, CS_2 37 and highly sulfonated castor oil (Avirol KM) 1.4 g. are mixed vigorously at low temp. for ½ hr. to a thin emulsion. Per sq. m. soil 1.42 kg. emulsion is used. Other insecticides can be added.

Citrate-soluble fertilizer from crude phosphate rock. Hans H. Franck and Franz J. Kaess (to Bayerische Stickstoff-Werke A.-G.). U. S. 2,183,379, Dec. 12. See Ger. 676,016 (*C. A.* **33**, 6516[8]).

Spray oil suitable for control of citrus pests. Ulric B. Bray (to Union Oil Co. of Calif.). U. S. 2,183,781, Dec. 19. Use is made of an extd. petroleum fraction having an A. P. I. gravity of about 23-27, an overall Sligh oxidation no. above 20, of which approx. 80% possesses

a Sligh oxidation no. between 15 and 25 and averaging about 20, the oil having a de Ong no. less than about 80.

Mineral oil mixtures for treating citrus fruits, etc. Wm. W. Bennett. U. S. 2,183,981, Dec. 19. Mixts. used are prepd. by combining approx. 4.5 parts of an acidulated animal fat such as acidulated tallow and 25 parts of acidulated vegetable fat such as acidulated coconut oil and heating the resulting mixt. for about 4 hrs. to about 180° at the end of the heating period, while agitating at intervals, and mixing the product with about twice its vol. of a mineral oil, etc.

Testing potatoes and the like for virus infection. Franz E. Eidmann. U. S. 2,183,553, Dec. 19. A method of testing and segregating diseased from sound tuber-seedlings comprises the steps of steeping longitudinal slices from the body of the tuber, immersing it in an aq solution of a salt of selenious acid for from 20 to 36 hrs. until a max. red coloration is attained, keeping the temp. at 30°, noting the difference in coloration of the different specimens, further subjecting the slicings to the action of the soln. to note further differentiation in color reaction, and then identifying and sepg. the specimens showing a gray discoloration from those retaining the original red coloration.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Melle process of alcoholic fermentation. F. Boinot. *Intern. Sugar J.* **41**, 466-7(1939).—By recovering the yeast and reusing it in subsequent fermentations a process has been developed which increases the yield of alc. as much as 28%. This is possible since only a little sugar is needed for the maintenance of the yeast and very little new yeast has to be produced. D. P. Langlois

Increased production of fusel oil in alcoholic fermentation. Yosinori Tomoda. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 379-80(1939).—Upon fermenting molasses, sweet potatoes or a synthetic medium composed of 10 g. of sucrose, 0.1 g. $CaCl_2$, 0.08 g. of KH_2PO_4 and 0.04 g. of K_2CO_3 by means of saké yeast in the presence (0.05-4.0 g./100 cc.) of $(NH_4)_2SO_4$, soybean cake, dry yeast, gelatin, casein, corn gluten meal, fish cake, wheat protein, *d*-alanine or *dl*-valine, the yields of fusel oil varied from 0.005 to 0.180 g./100 cc. of fermented liquor. Nitrogenous substances in general increase the yield of fusel oil, *dl*-valine having the greatest effect. $(NH_4)_2SO_4$ retards the effect of the nitrogenous substances on the yield of fusel oil. Previous elimination of NH_3 from the hydrolyzed product of nitrogenous materials favors the production of fusel oil, as does the use of activated carbon or wood charcoal in the sugar mash. George Ayers

The alcoholic-fermentation balance must logically be revised; aeration of the wort in industrial fermentation is not to be recommended. J. Pérard. *Bull. assoc. chim.* **56**, 724-7(1939).—Reply to Savary (*C. A.* **33**, 6518[8]). F. W. Zerban

The Pasteur coefficient. F. Boinot. *Bull. assoc chim.* **56**, 728-32(1939); cf. preceding abstr.—Reply to Savary (*C. A.* **33**, 6518[8]). F. W. Zerban

Investigations on foaming, with special reference to problems of applied chemistry. I. Wo. Ostwald and W. Mischke. *Kolloid-Z.* **90**, 17-25(1940); cf. *C. A.* **30**, 6620[1].—A new app. for the analysis of foam and sepn. of its component parts is described. An aq. soln. contg. 0.1% "Patent Blue" and "New Cocein" was used in these expts. The "Patent Blue" is a surface-active material while the "New Cocein" is not surface-active. The surface-active dye is sepd. in the form of foam (with a current of N_2) from the other material and water. A min. concn. of the surface-active material is necessary to cause foam formation. The completeness of sepn. of the two dyes is dependent on the ratio of their concns. in the soln., and on the velocity of foam formation. II. W. Mischke. *Ibid.* 77-89.—The foam problem of beer was studied. Model expts. were carried out with gelatin for studying the most important variables of foam formation, such as concn., foam pressure, foam permanence, width of the gas jet openings, and addn. of acid and alkali. A method for detg. the "dynamic foaming capacity" was worked out and used for comparing various beers. This method gave results similar to those obtained with the Schuster and Mischke (*C. A.* **32**, 1396[3]) method. By means of foam analysis those beer components responsible for foam formation could be distinguished and concd. The albumoses are the protein components mainly responsible for foaming, while of the other materials present in beer, the dextrins and hop resins are the main foaming constituents. The hop resins concentrate to the greatest extent in the foam, being removed practically quantitatively from the beer by this means. A systematic investigation of a large no. of beers showed a definite relationship between the albumose content and foaming value (dynamic foaming capacity). This foam analysis method can be used to det. the foaming capacity of particularly effective albumoses during the manuf. of beer. Fifty-eight references. S. I. Aronovsky

The effect of selenium and arsenic at various ratios on the fermentation of glucose by bakers' yeast. Henry A Lardy and Alvin L. Moxon. *Proc. S. Dakota Acad. Sci.* **19**, 109-11(1939).—The prevention of Se toxicity by means of As is not as specific in fermentation as it is in the case of feeding trials with animals. Arsenite does prevent selenite toxicity to some extent. Walter H. Seegers

Titrimetric determination of alcohol in malt liquors. T. Voitila. *Suomen Kemistilehti* **12A**, 33-5(1939); cf. *C. A.* **33**, 8352[3].—Pycnometric and titrimetric methods of detg. EtOH in beer give values agreeing to within 0.2%. App. is described. B. C. P. A.

Use of the Dujardin-Salleron ebulliometer for the determination of the alcoholic strength of wines. C. R. Churchward and B. G. Johns. *Australian Chem. Inst. J. & Proc.* **7**, 18-30(1940).—The instrument gives concordant results if obvious sources of error are avoided. A new table for distillates and for standardization of thermometers is given. O. W. Willcox

The wines of Ciró. I. Study of the chemical composition of typical wines of southern Italy. F. Sallusto and L. Scuteo. *Ann. ist. super. agrar. Portici* **9**, 121-54(1937-38).—The max., av. and min. values are given for 26 wines of d. at 15°, alc. in vol. per 100 cc., dry ext., reducing sugars, glycerol, total acids (as tartaric acid), tartaric acid, K bitartrate, lactic acid, AcOH, tannic acid (coloring matter excluded), succinic acid, fixed acidity, ash, phosphates, and Halphen ratio. A. R. Merz

The composition of some natural wines of southern Italy. Federico Sallusto. *Ann. ist. super. agrar. Portici* **8**, 3-33(1936-37).—The total acids (as tartaric acid) and sugar in 77 varieties of grapes and the d. at 15°, alc., dry ext., glucose, glycerol, total acid (as tartaric acid), fixed acid, ash, P_2O_5, tannin, etc., of the wines prepd. therefrom are reported in tables. A. R. Merz

Ferric casse and curative remedies. Federico Sallusto. *Ann. ist. super. agrar. Portici* **9**, 248-56(1937-38).—Al(OH)$_3$ 0.50, kaolin 1.5 or animal charcoal 1 g. per l. serves well to cure blue casse in wines. They do not modify the chem. and organoleptic characteristics. A. R. Merz

Varietal differences in barleys and malts. VIII. Correlations between enzymic activities and malt extract, malting loss, and steeping time. Henry R. Sallans and J. Ansel Anderson. *Can. J. Research* **18, C**, 35-41(1940); cf. *C. A.* **32**, 7655[9]; **34**, 215[2].—Significant neg. intervarietal correlation coeffs. between steeping time and barley - saccharifying (−0.706), malt - saccharifying (−0.814), starch-liquefying (−0.954), autolytic diastatic (−0.937), and proteolytic (−0.822) activities are shown to be dependent on the same fundamental barley properties as similar pos. coeffs. between these activities and

salt-sol. barley N. Barley- and malt-saccharifying and proteolytic activities are equally assocd. with both salt-sol. N and steeping time, but starch-liquefying and autolytic diastatic activities are more closely assocd. with the latter property. Significant intervarietal correlation coeff. were obtained between liquefying, autolytic, and proteolytic activities and malt ext. and malting loss. Partial correlation studies indicate that only the simple coeff. between malting loss and proteolytic activity (0.915) represents a real relation independent of salt-sol. N and steeping time. With the exception of autolytic diastatic activity, highly significant intravarietal correlation coeffs. were obtained between malt ext. and enzymic activities. Partial coeffs., independent of total N, show that proteolytic, liquefying and autolytic activities are assocd. with malt ext. Simple intravarietal correlations of malting with barley-saccharifying (0.671), malt-saccharifying (0.702), and proteolytic (0.701) activities reflect mainly the effects of total N. Enzymic activities are negatively correlated with steeping time within as well as between varieties, and partial correlation coeffs. suggest a real relation between liquefying activity and steeping time. J. W. Shipley 1

The quality of Slovak must of the 1937 season. Stan Kopal. *Winzer* **4**, 4-6(Jan., 1938); *Chem. Zentr.* **1938, I**, 1241; cf. *C. A.* **33**, 3060⁸. The white must of the 1937 vintage had an av. sugar content of 19.6% and an acid content of 7.6%. These values for the red must were 19.4% and 9.1%. M. G. Moore 2

Technological, chemical and regulatory study of Argentine grape "chicas." José Testa. *Univ. Buenos Aires, Facultad agron. y vet., Inst. ind. agr.* **1**, No. 2, 32 pp. (1939).—Chichas are prepd. in various grades of alc. and sugar content by partial fermentation of natural or boiled and concd. grape juice which has been previously detartratized by chilling. Alc. ranges from 2 to 13.6%. The chichas are champagnized with CO_2 to pressures of 2-4 atms. Analyses of typical Chilean and Argentine chichas are given. O. W. Willcox 3

The nature of bitter principles. E. Wagner. *Deut. Destillateur-Ztg.* **59**, 174(1938); *Chem. Zentr.* **1938, I**, 4546.—Tabular. A review of the drugs used as bitters in the manuf. of spirits with suggestions for the substitution of domestic (German) for foreign products. In addn. to taste and odor, the medicinal action is noted. M. G. M. 4

The possibility of the manufacture of light caoutchoucin in the U[nited] P[rovinces] and detection of adulteration in commercial samples. S. N. Ghatak and K. C. Mukherji. *J. Sci. Tech., India* **4**, 33-8(1938).—Light caoutchoucin (I), used for denaturating spirit, is obtained by the distn. of *waste rubber* in 15% yield by wt. A cost sheet indicates the practicability of manufg. I on a local scale (1330 gal in 4 months). From the analysis for excise purposes of I and suspected adulterants, it is recommended that material showing optical activity be rejected. A liquid of the turpentine class is presumably the adulterant. Specifications for I are listed as well as sp. gr., specific rotation, n_D^{15} and I-value detns. on I and adulterants. A. J. S. 5

A case of corrosion in the distillery. Y. K. Raghunatha Rao. *Intern. Sugar J.* **41**, 438-9(1939).—When sulfitation cane molasses is used as a raw material corrosion occurs in the mild-steel fermentation tanks especially around the rivets. The distg. plant being of copper does not corrode except on the top plate of the rectifier. The corrosion deposit on this plate was a basic copper sulfate indicating that the SO_2 liberated from the molasses by the added H_2SO_4 had mixed with air admitted by the vent pipe and thus corroded the top plate. This corrosion was found to be proportional to the SO_2 content of the molasses. It can be diminished by vigorous aeration of the soln. but since the SO_2 is very sol. it cannot be completely removed from the fermentation wash. D. P. Langlois 6

Manufacture of yeast from molasses. S. Rajagopal. *Proc. Soc. Biol. Chemists, India* **2**, 41(1937).—Some preliminary expts., not described, have been made to study conditions. B. C. P. A. 7

Digesting sulfite pulp and getting high yield of alc. (Johansson) **23**. Yield of alc. from waste liquor from sulfite digesting and retention of strength of pulp (Bergson) **23**. 8

Frey, Alfred, and Sichert, Karl: Leitfaden fur die Obst- und Beerenweinherstellung. Braunschweig: Serger & Hempel. 71 pp. M. 1.

Fermenting whey for alcohol production. Willem Kauffmann and Pieter J. van der Lee. U. S. 2,183,141, Dec. 12. A method of treating whey comprises adding to pasteurized whey a pure culture of yeast of the kind traceable in Gervais cheese, the culture being selected from a series of similar cultures, which were obtained from starting materials which contain yeast microörganisms capable of fermenting lactose, and having been found capable of converting more than about 65% of the lactose present in the whey into EtOH within not more than three days. A temp. of 10-45° and a pH of 4.5-7.0 are suitable for the fermentation of the whey.

Denatured alcohol. Louis J. Figg, Jr., and James W. Rhea (to Eastman Kodak Co.). U. S. 2,184,010, Dec. 19. As a denaturant, use is made of 0.5-5% of methyl or ethyl amyl ether, alone or together with other denaturants such as mixed ketones. Cf. *C. A.* **34**, 1810⁸.

Yeast. Robert R. Irvin and Morris W. Mead, Jr. U. S. 2,183,570, Dec. 19. A process of making yeast by the aeration method comprises setting a fermenter with a soln. of yeast nutrients, seeding the wort with seed yeast in an amt. of 3.5-15% of the total nutrients used, commencing propagation of yeast by aerating at a comparatively low rate while adding a further quantity of nutrients in an amt. such that 20-45% of the total nutrients are in the fermenter when 35-50% of the total time of the process has elapsed, then adding water to the fermenter, and thereafter continuing propagation by aerating more rapidly and by adding the remainder of the nutrients during the remaining period of time. Examples are given involving use of a soln. of molasses, NH_4 salts and aq. NH_3 soln. as nutrients for the yeast.

Apparatus for destroying froth developed in yeast manufacture or other processes. Johan O. Naucler. U. S. 2,184,195, Dec. 19. Various structural and operative details of an app. adapted for projecting the froth into an atm. in the form of a rapidly rotating, spreading layer of froth which is permitted to spread for breakage and coalescence of the froth bubble material.

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

Chemical studies in connection with the dosing of sheep with phenothiazine. M. Lipson. *J. Council Sci. Ind. Research* **12**, 342-4(1939).—Com. phenothiazine is purified by dissolving in boiling benzene and then sucking the soln. through a benzene-wetted alumina column. Evapn. of the red soln. coming from the column leaves a residue which consists of phenothiazine contaminated with a small amt. of a red impurity. This impurity is removed by powdering the residue and washing with hot petroleum ether. This leaves pure phenothiazine as a residue. In spite of the extreme soly. of phenothiazine in acetone, this solvent does not remove it quantitatively from feces. The routine *analysis of feces for phenothiazine* is accomplished by drying the sample at 100° for 2 hrs. and then extg. with alc. in a Soxhlet app. for 4 hrs. On cooling, the ext. is made up to vol., an aliquot is taken, and the phenothiazine is estd. colorimetrically (cf. Eddy and DeEds, *C. A.* **32**, 1004⁹). J. R. Adams 9

Reineckate and silicotungstate of narcotine and a contribution to the estimation of that alkaloid. P. Duquénois

and M. Ellert. *Bull. soc. chim.* **6**, 1582–6(1939).—Treatment of acidulated aq. narcotine-HCl with a satd. soln. of Reinecke salt gave an amorphous rose powder, $C_{22}H_{23}NO_7 \cdot Cr(NH_3)_2(SCN)_4$, sol. in H_2O to the extent of 0.003 g. and 0.02 g. in 100 cc. at 3 and 20°, resp. The soly. in H_2O contg. 1% HCl is slightly greater. In 100 cc. of 95% alc. at 20° the soly. reaches 3.4 g. The reineckate can be used for the quant. estn. of narcotine provided that a close-grained sintered-glass filter is used and allowance is made for the soly. of the salt in cold H_2O. Narcotine-HCl in 1% HCl was treated with a slight excess of 5% silicotungstic acid and the mixt. was heated to boiling. After 24 hrs. the ppt. was filtered off, washed and dried to const. wt. Narcotine silicotungstate, $4C_{22}H_{23}NO_7.SiO_2.12WO_3.2H_2O$, when dried over $CaCl_2$ in a desiccator contains $7H_2O$, which is lost on drying at 105°. The soly. is a few mg. in 100 cc. H_2O at 20°, very slight in dil. HCl, 5 g. in 100 cc. acetone at 20°, slight in alc., and practically nil in ether. Although the reineckate gives good results, estn. by the silicotungstate is the best, provided that pptn takes place in dil. HCl (contg. 1 part of official HCl per 100 parts of H_2O), the ppt. is washed with 0.01 *N* HCl and is dried at 105°. C. R. Addinall

Organic sulfur compounds in antibacterial chemotherapy. Angelo Ferraris. *Boll. chim. farm.* **78**, 597–604 (1939).—Review of recent work on sulfanilamides. C. R. Addinall

Vitamin A and D potencies of liver and intestinal oils of red, black and ling cod. L. I. Pugsley. *J. Fisheries Research Board Can.* **4**, 472–7(1940); cf. *C. A.* **34**, 1127[6]. —The vitamin A (I) potency of the liver and intestines and the oils derived therefrom tends to increase with the size of the fish in the red cod (II) (*Sebastodes* sp.), black cod (III) (*Anoplopoma fimbria*) and ling cod (IV) (*Ophiodon elongatus*), none of which belongs to the true cods of the Gadidae. Pooled samples of liver and of intestinal oils of II, III, and IV show 54,250, 75,000; 101,750, 14,350; and 245,000, 55,500 blue units of I per g. and —, 100; 4000, 500; and 6000, 100 international units per g. of vitamin D. The liver oils are good sources of I but the intestinal oil has a lower I content than halibut. This is due to diln. of the I in the tunica propria by the relatively large amt. of I-poor oil from the mesentery. The scanty information regarding vitamin D indicates that the liver oils of II and IV are poor. Tabulations of data on seasonal variations and yields from organs in relation to wt. of fish are given. C. R. Addinall

Bitter constituents of the sap of Lactuca virosa, L. VI. Preparation of lactucin. E. Späth, G. Schenck and W. Schreiber. *Arch. Pharm.* **277**, 203–6(1939); cf. *C. A.* **33**, 7041[7]. —The yield of lactucin (I) from the dried powder is increased to 7.2% by treating the aq. soln. with HCl, neutralizing with $NaHCO_3$, and extg. with Et_2O. The acid coagulates a colloid, which retains I in aq. soln. B. C. P. A.

Distillation and distillation technique in the perfume industry. I. Herold. *Deut. Parfum.-Ztg.* **25**, 106–8 (1939).—An account is given of elementary principles involved in distn. practice and the application of the process in the prepn. of perfumery products (essential oils and isolates). B. C. P. A.

Chemical and biological assays of the tertiary alkaloids, quaternary bases and galenical preparations of Phaeanthus ebracteolatus (Presl) Merrill. Faustino Garcia and Araceli A. Ylagan. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 233–43(1939).—See *C. A.* **34**, 1442[9]. A. D.

Studies on the essential oil from the rhizome of Acorus calamus. I. Isolation and examination of calamol. Muhammad Qudrat-i-Khuda, Asutosh Mukherjee and Subash Kumar Ghosh. *J. Indian Chem. Soc.* **16**, 583–8 (1939).—The rhizome from Ghore Bacha was cut into small pieces and crushed as fine as possible. The finely divided material (200 g.) was mixed with 400 cc. of H_2O and then distd. in steam for 6 hrs. The total distillate amounted to 7 l. This was satd. with NaCl, extd. twice with Et_2O, the ext. dried over fused $CaCl_2$, and the solvent removed. The residual oil was fractionally distd. under reduced pressure to produce calamol ($C_{12}H_{16}O_3$ or $C_9H_{11}O_2$-$CH_2CH{=}CH_2$) (I). The yield was 7.88%. The oil was a colorless, mobile liquid with a strong and rather pleasant aromatic odor. It had b_5 153–4°, $d_4^{30.1}$ 1.07021 and $n_D^{30.1}$ 1.55012. I was converted to *isocalamol* ($C_9H_{11}O_2$-$CH{=}CHCH_3$) (II) by heating it under reflux for 10 hrs. with alc. KOH. II had: b_2 133°, $d_4^{21.8}$ 1.07261 and $n_D^{21.8}$ 1.55229. The *Br deriv.* of I was prepd. by adding a soln. of Br in petr. ether to a soln. of I in the same solvent. The purified deriv. decompd. rapidly on distn. and its identity with $C_{12}H_{14}O_3Br_4$ could not be definitely established. Catalytic hydrogenation of I gave *dihydrocalamol* ($C_{12}H_{18}O_3$), b_2 124°, $d_4^{21.2}$ 1.03109, $n_D^{21.2}$ 1.51219. Demethylation of I with $AlCl_3$ yielded $C_{11}H_{14}O_3$ (b_2 115°), this indicates that only 1 methoxyl group was lost. Demethylation with HI followed by benzoylation gave $C_{26}H_{22}O_6$, m. 96°. Oxidation of I by alk. $KMnO_4$ produced *calamonic acid* or *trimethoxybenzoic acid* ($C_{10}H_{12}O_5$) (III), colorless needles, m. 143°. Oxidation of II under the same conditions also yielded III. *Trihydroxybenzoic acid* (colorless crystals, m. 97°) was formed when III was demethylated by treatment with HI. 12 references. L. Wilson Greene

Swedish pine-needle oil and its components. Wilhelm Sandermann. *Seifensieder-Ztg.* **66**, 803, 833–4, 863–4 (1939); **67**, 15–16, 45(1940).—The yield of oil from pine (*Pinus sylvestris* L.) needles differs according to season (Dec. 0.22%; Apr. 0.25%; June 0.34%). Heating of small branches with the needles has little effect on the oil. Sp. gr. of the oil increases slightly with increasing pressure during distn. At pressures above 2 atm., a scorched odor becomes evident. Distn. with injected dry steam carries over the terpenes in large part before the heavier portions. When boiling with water, terpenes and heavier bodies distil together. Ten kg. oil was distd. under vacuum and collected in 43 fractions and a residue. Density, *n*, b. p., as well as ketone values and alc. solv., and proportions of esters, ketones plus aldehydes, and alcs. are tabulated for all fractions. The typical odor is carried by only a few fractions. The com. "terpene- and sesquiterpene free" oil is obtained in about 2.5% yield but does not carry all of the odor value. Terpenes and sesquiterpenes can be pptd. from alc. soln. by diln. with water. This method may be combined with fractional distn. A table gives for 16 typical components, the limiting dilns. with water for clear solns. in EtOH and MeOH. Increasing proportions of water are permitted, in order, for instance, by sesquiterpene, pinene, bornyl acetate, terpineol. Over 60% of the oil consists of terpenes, including α-pinene, β-pinene, Δ³-carene, dipentene, α-phellandrene, limonene, β-phellandrene. A sesquiterpene, cadalene, is present. Numerous aldehydes, have, together, odors of cuminaldehyde and anisaldehyde. An acid was found b_7 190–208°, m. (recrystd. from methanol) 56–60°; calcd. for $C_{13}H_{20}$-COOH: C = 74.3; H = 11.5; found C = 74.20; H 11.64%. With $FeCl_3$ the first phenolic fraction (130–145° at 5 mm.) is violet, later fractions (to 190° at 5 mm.) colorless. Borneol was found combined, but not free. A. Guillaudeu

Action of formic esters in perfumes. Th. Ruemele. *Seifensieder-Ztg.* **67**, 56, 65(1940).—Me, Et, Pr, iso-Pr, Bu, iso-Bu, Am, iso-Am, hexyl, heptyl, octyl, nonyl, decyl, linalyl, geranyl, citronellyl, bornyl and menthyl formates are discussed. A. Guillaudeu

Advantages of a physically balanced alcosaline compound over rubbing alcohol. Hyman Lischner. *J. Am. Inst. Homeopathy* **33**, 87–93(1940).—A soln. with the percentage compn. H_2O 77.00, alc. 20.00, NaCl 2.40, KCl 0.06, $CaCl_2$ 0.06, $MgCl_2$ 0.03, $NaHCO_3$ 0.01, Na_2HPO_4 0.01, $MgSO_4$ 0.25, tinct. I 0.02, pine oil 0.50 is superior to rubbing alc., which has a hardening, drying effect on the skin, and is an irritant. The soln. has stimulating, antiseptic, deodorant, and solvent properties. 52 references. Joseph S. Hepburn

Quantitative colorimetric assay of adrenaline and morphine by the iodoxybenzoate reaction. C. Robert Moodey and G. A. Emerson. *Univ. Calif., Pub. Pharmacol.* **1**, 235–47(1939).—*o*-Iodoxybenzoates react with

phenolic compds., including adrenaline and morphine, and with aromatic amines to yield colored compds. In assays for morphine and adrenaline by this reaction, the reaction time, iodoxybenzoate concn. and pH must be controlled to obtain accurate results. Since the colored products of the reaction are unstable, a calibrated Pulfrich photometer should be used in routine analyses. 22 references.

Stability of ichthyol preparations. H. Parts. *Pharmacia* (Estonia) **20**, 2(1940).—When kept under proper conditions the prepns. do not lose appreciable amts. of sulfide S. T. Laanes

Modern principles of biological assay methods. J. Rimments. *Pharmacia* (Estonia) **20**, 6–11(1940).—A review, chiefly of *digitalis* prepns. and their standardization. T. Laanes

Assay of magnesium peroxide tablets. August Siim. *Pharmacia* (Estonia) **20**, 17–19(in German, 19)(1940); cf. C. *A.* **33**, 7958⁴.—The tablets lose some of their MgO_2 content on standing. It is advisable to det. the MgO_2 before their prepn. and avoid prolonged storage. Manganometric titration is a simple and rapid method for detn. of MgO_2. A crushed tablet is placed in a 100-cc. measuring flask, covered with dil. (1.4) H_2SO_4, dissolved and water added up to the mark. After the starch is filtered off 20 cc. of the fluid is titrated with 0.1 *N* KMnO₄ permanganate until there is a stable rose coloring. Twenty cc., contg. 0.025 g. MgO_2, should require at least 8.8 cc. of the standard soln., corresponding to 0.1235 g. (or 25%) of MgO_2 in a 0.5-g. tablet. T. Laanes

Bioassay of the antianemic potency of liver. Maria T. Capsoni. *Biochim. terap. sper.* **26**, 449–60(1939).—Daily intravenous injections of increasing doses of basic Pb acetate up to a total of 40–41 mg. Pb produce in the rabbit a severe anemia that lasts for a month and then is followed by gradual recovery. If a total of 15 mg. only is given, the anemia is intense but quite unstable. Injections of potent liver ext. lead to prompt remissions. This method lends itself to bioassay on a comparative basis.

Metallic pectin compounds in therapy. A. Ravina. *Presse méd.* **47**, 1223–4(1939). A. E. Meyer

Injectable solutions of barbiturates. Haydee N. Berasain and Hector Vitali. *Rev. farm.* (Buenos Aires) **81**, 63–73(1939). Phenobarbital-Na is unstable in solns. The stability is improved at a lower *p*H but aq. solns. are still unsatisfactory. A soln. of 10 g. phenobarbital in 40 cc. propylene glycol and 100 cc. H_2O can be sterilized by heat (15 min.) and remains unchanged on storage.
A. E. Meyer

Pharmaceutical chemistry and the art of healing. O. F. P. Otzen. *Pharm. Tidjschr. Nederland.-Indie* **15**, 65–70 (1938); *Chem. Zentr.* **1938**, I, 4494.—A report concerned with the cooperation of chemist and physician in the discovery of medicinal prepns. M. G. Moore

Naphthalan petroleum. V. I. Feldman. *Sovet. Vestnik Venerol. i. Dermatol.* **1936**, 1035–41; *Chem. Zentr.* **1938**, I, 4355.—A preliminary report. The use of naphthan petroleum (I) in the form of salves with talcum and vaseline gave good results in the treatment of a series of skin disorders. No undesirable effects were observed. Naphthalan is to be distinguished from I. It is produced from I by heating to 200° with fresh, neutral stearin soap. I is an oily, black-brown liquid with a faint odor; d. 0.953–0.963, flash point 140–70°. It is insol. in water and glycerol, sol. in $CHCl_3$, in ether, and partially so in 95% alc. It mixes well with fats. It is distinguished from tech. petroleum in that it contains neither benzine nor kerosene and gives no paraffin on distn. On the other hand, it does contain olefins and saponifiable O compds., phenols, vaseline and slight amts. of S combined in org. radicals.
M. G. Moore

The effect of the conditions of storage on the quality of finished products (tobacco products). V. S. Kushlyu and A. V. Shageyeva. *Tabak S. S. S. R.* **8**, No. 3, 24–8 (1938); *Chem. Zentr.* **1938**, II, 3477.—Maintenance of a relative humidity of 60% and hermetic sealing were found to be the best conditions for the storage of finished tobacco products. Cigarets stored under these conditions lost relatively large amts. of reducing substances; the Leningrad no. became smaller; however, the crude resins increased so that the consts. became smaller than when the cigarets were stored at a relative humidity of 40%. With long storage of cigarets a slow decrease in the nicotine content occurred. A loss of strength was first detected after 10-months' storage. The total alky. decreased up to the 5th month, then increased again during further storage. Also, the total N was higher in the 8th month than at the beginning of storage. On the other hand, the polyphenol content increased during the first 5 months of storage and later decreased. Thus, 8 months is to be regarded as a max. period of storage. The aroma, strength and taste are all impaired when storage is longer than this.
M. G. Moore

The bactericidal power of the six isomeric xylenols and their monochloro and monobromo derivatives. G. Lockemann and K. Heicken. *Zentr. Bakt., Parasitenk.*, I Abt., Orig. **145**, 61–71(1939).—Little is known of the bactericidal power of the xylenols because of their insoly. in water. When the monochloro derivs. of the 6 isomers were tested against *B. coli*, 4-chloro-2,3-xylenol (I), 4-chloro-3,5-xylenol (II) and 4-chloro-2,5-xylenol (III) were 4 times as strong as 6-chloro-3,4-xylenol (IV) and 6-chloro-2,4-xylenol (V). Against *Staphylococcus aureus* I, II and III were 15 times as strong as V. The Br derivs. corresponding to I, II and III were 6 times as strong as IV and V against *B. coli* and 33 times as strong against *S. aureus*. John T. Myers

The disinfection of instruments with Zephirol. Annelise Winkler and Kurt Redecker. *Zentr. Bakt., Parasitenk.*, I Abt., Orig. **145**, 72–80(1939).—Zephirol (0.5–1.0% aq. soln.) sterilized dental instruments in 10–15 min. The addn. of $NaNO_2$ did not decrease the disinfecting power but prevented corrosion for as long as 8 weeks.

Effect of cigaret holders filled with extraction materials on the smoke. Constantin Pyriki. *Z. Untersuch. Lebensm.* **78**, 470–6(1939).—Com. cigaret holders contg. silica gel, C or a clay-like substance removed 10.3–16.2% of the nicotine and about the same amt. of tarry material from cigaret smoke. P. concludes that the smoke stream is too rapid for satisfactory filtering by the absorbent.
M. M. Piskur

Petroleum cresylic acids, their composition, manufacture and use in disinfectants. D. B. Luten, F. A. Bent and M. L. Griffin. *Soap (Sanitary Products Sect.)* **16**, No. 1, 97, 99, 101, 103, 105, 107, 119(1940).—In the lower-boiling ranges, alkyl phenols derived from cracked petroleum distillates are identical in many cases with those derived from coal tar. The compds. are closely related in higher-boiling ranges. The higher-boiling fractions of petroleum alkyl phenols are satisfactory as saponified phenolic disinfectants. Formulas are given. The finished products did not change significantly on 6-months' aging. Toxic effects from skin application of these disinfectants

are less severe than those made from lower-boiling alkyl phenols. Henry H. Richardson

Athlete's foot prophylaxis. Clarence L. Weirich. *Soap (Sanitary Products Sect.)* **16**, No. 2, 88, 89, 103(1940).—Five-25% solns. of $Na_2S_2O_3$ had no fungicidal effect against *Trichophyton rosaceum* and other fungi (1 min. exposure at 20°). One hr. exposure to a 15% soln. gave no kill. Coal-tar and pine-oil disinfectants (coeff. 6) showed little efficiency. A skin patch test should be made for detecting irritating or unsafe chemicals. A soln. of Na *p*-bromophenylphenate was found irritating. Hypochlorite solns. retain their efficiency over a period of days but solns. of higher phenols are seriously affected by air oxidation. Henry H. Richardson

Alkyl phenolic disinfectants from petroleum and the commercial standards. Emil Klarmann. *Soap (Sanitary Products Sect.)* **16**, No. 2, 90–2(1940).—Changes in the disinfectant standard specifications are recommended so as to include alkyl phenolic products from petroleum. Henry H. Richardson

Significance of capillary analysis for physical therapy. H. Lampert and H. Röhlinger. *Kolloid-Z.* **89**, 271–86 (1939).—The compn. of different kinds of mucks can be examd. by the addn. of 96% alc. In this way the amt. of org. matter present can be detd., and also whether the compn. has been changed artificially. Felix Saunders

Alkaloid content of extractum hyoscyami. J. A. C. van Pinxteren. *Pharm. Weekblad* **76**, 1629–31(1939). The alkaloid content of hyoscyamus ext. varies from 0.65 to 0.20%. Felix Saunders

Precipitation of alkaloids by cuprous chloride. J. J. L. Zwikker and A. Kruysse. *Pharm. Weekblad* **77**, 18–22 (1940).—Prepn. of reagent: Dissolve 200 mg. $CuCl_2$ in a few cc. of water and add to the soln. 250 mg. Na_2SO_3 dissolved in 5 cc. of water. Add 2 cc. of 1 *N* HCl and make up to 10 cc. Test: Dissolve a little of the alkaloid in water (1:20) with a little HCl. The following alkaloids give a pos. test: aconitine, apomorphine, berberine, brucine, cevadine, cinchonidine, cinchonine, cocaine, codeine, caffeine, cotarnine, dionine, emetine, heroine, hydrastine, quinidine, quinine, narceine, narcotine, papaverine, strychnine, thebaine, theophylline, veratrine and yohimbine. A neg. test is given by: adrenaline, atropine, colchicine, coniine, cytisine, ephedrine, homatropine, morphine, nicotine, novocaine, physostigmine, pilocarpine, piperine, scopolamine, solanine, sparteine and tropine. Felix Saunders

Refining of Mayur Pankhi oil (Thuja orientalis). S N. Ghatak and K. C. Mukherji. *J. Sci. Tech., India* **4**, 39–41(1938).—Distn. of a mixt. of H_2O and the sawdust of the wood of the Mayur Pankhi tree yields an orange-colored oil, used to scent tobacco. It is insol. in 70% EtOH and quite different from the ordinary oils of *Thuja*. Neither norite char, Torneo earth nor acid solns. of permanganate or persulfate improved the color, but an acid soln. of perborate was partially successful. The yield, color and odor are satisfactory when steam- or vacuum-distn. methods are used, but steam distn. is expensive and time-consuming. The properties of the original and the vacuum-distd. oils (b_{10-39} 160–205°) are, resp.: d_{30}: 0.9774, 0.9598; $[\alpha]_D^{25}$: −12.9, −20.9; n_D^{25}: 1.5030, 1.5000; acid value: 21.0, 19.8; ester value in terms of MeOAc: 2.96, 2.96; color (detd. with the Lovibond tintometer): yellow 3.5, red 0.6 and yellow 0.5, red 0.0. A. J. Stirton

Analytical results on the seasonal variations of the juice of cherry laurel leaves. A. Leulier and L. Tuarze. *J. pharm. chim.* **29**, 544–9(1939); cf. *C. A.* **34**, 4663.—Monthly records (Feb. 1937–Feb. 1938) are tabulated for reducing sugars before and after hydrolysis, total N, S after removal of phosphates, P, Na, K, Mg, d., f. p., dry ext. and ash detd. in the expressed juice of the leaves. The results are discussed and compared with other records (cf. Canals, *C. A.* **23**, 3003, 4967). S. Waldbott

Evaluation of pentamethylenetetrazole preparations; cardiazole, tetrachor. Gyula Miko. *Pharm. Acta Helv.* **14**, 31–4(1939).—This drug (*A*), a heart stimulant, m. 56–58°, is injected in the form of a 10% soln., or given in tablets each contg. 0.10 g. *A*. To identify *A* in soln., evap. 5 cc. to 0.6 g., then *in vacuo* over H_2SO_4 to 0.5 g.; take up with 5 cc. H_2O and add 25 cc. of 5% aq. $HgCl_2$. After 10 min. filter and wash the ppt. with two 5-cc. portions of ice water, then recrystallize from hot water; det. m. p. (176°). This compd. contains 48.6% Hg. Det. this in 0.3 g. of the Hg salt. Add 50 cc. H_2O, 1 g. KI, 3 cc. 35% CH_2O and 15 cc. 5 *N* NaOH; shake for 2 min., add 20 cc. 33% AcOH and 30 cc. 0.1 *N* I. Shake well until the Hg is dissolved (10 min.) and titrate the excess of I with 0.1 *N* $Na_2S_2O_3$ soln. Each cc. of I soln. = 0.01003 g. Hg To det. *A* in tablets, ext. 5 tablets with alc., evap. and proceed as above. S. Waldbott

Double cyanide gauze, Brit. Pharm. Codex. R. Maxwell Savage. *Pharm. J.* **142**, 614(1939).—Black edges and longitudinally running discolored strips were probably caused by HgS. S. Waldbott

Iodine and ash of sponge. A. Tschirch. *Schweiz. Apoth.-Ztg.* **77**, 85–6, 313–14(1939).—J. C. Straub, Coindet and Fyfe (Edinburgh) in 1819 simultaneously found I (discovered 1812 by Courtois) in *Carbo spongiae* (*Spongia usta*), long reputed to be a remedy for goiter This medicinal use probably dates back to the Salernian School (13th century) and not merely to the plant-ash therapy of *Salva Tacheniana* (Otto Tache, *Hippocrates chymicus*, 1666; cf. *Tsch., Handbuch*, Vol. I, p. 1697). Sponge ash was official in pharmacopeias of the 18th and 19th centuries, last in Pharm. Helv. I (1865). The external and internal uses of KI ("Kropfsalbe"; iodized salt) are referred to. S. Waldbott

The luminescence (fluorescence) of essential oils in filtered ultraviolet light. Arno Muller. *J. prakt. Chem* **154**, 209–18(1940). Of 252 compds. 160 showed a more or less violet luminescence, 37 a bright violet, 22 a pale greenish, 10 a bright white-green, and 10 a bright yellow-green color. Groups examd. are ales., aldehydes, ketones, esters, ethers, acetals, lactones, phenols, N compds., hydrocarbons, acids and 2 halogen compds. The various groups are classified according to the nature of the luminescence. C. J. West

Amino aliphatic sulfonamides. Walter G. Christiansen (to E. R. Squibb & Sons). U. S. 2,184,279, Dec. 26 Compds. suitable for combating invasions of streptococci, etc., and which have the general formula $R^3R^4NXSO_2NR^1R^2$, where X is an aliphatic hydrocarbon group having no more than 6 C atoms, R^1 and R^2 represent each a H, lower alkyl or hydroxy-lower-alkyl, and R^3 and R^4 represent each a H or lower alkyl; and acid addn. salts thereof are prepd. by a process, in the case of compds. of the general formula $NH_2XSO_2NR^1R^2$ which comprises treat-

ing a compd. of the general formula  halogen with an alkali metal sulfite, converting the resulting sulfonate into the corresponding sulfonyl halide, treating the sulfonyl halide with NH_3 or an alkylamine or hydroxyalkylamine, and converting the resulting phthalimido aliphatic sulfonamide into the corresponding amino aliphatic sulfonamide by hydrolysis. Details are given of the production of: the Na salt of 2-phthalimidoethanesulfonic acid; 2-phthalimidoethanesulfonyl chloride; 2-phthalimidoethanesulfonamide, m. about 201–6°; 2-aminoethanesulfonamide-HCl, m. about 133°; 3-amino-1-propanesulfonamide; 1-amino-2-butenesulfonamide; 4-aminocyclohexanesulfonamide; and general mention is made of the production of other compds., e. g., by using $MeNH_2$, Et_2NH, diethanolamine or propanolamine, the compds. obtained are, respectively, 2-aminoethane-*N*-methylsulfonamide, 2-aminoethane-*N*,*N*-dimethylsulfonamide, 2-aminoethyl-*N*,*N*-bis(hydroxyethyl)-sulfonamide, and 2-aminoethyl-*N*-hydroxypropylsulfonamide. Compds. wherein either or both of $R^{3,4}$ and $R^{5,6}$ are alkyl groups instead of H may be prepd. from the corresponding nonalkylated compds. by alkylating in the conventional manner; e. g., *N*,*N*-dimethyl-2-aminoethylanesulfonamide may be prepd. by treating 2-aminoethanesulfonamide with Me_2SO_4.

Ampoules suitable for holding arsphenamine and solvent liquid in separate compartments. Jacob A. Saffa U. S. 2,184,152, Dec. 19. A multicellular ampoule is formed of nonmagnetic material such as glass, and is provided with a plurality of sealed cells sepd. by partitions of frangible material such as glass one at least of which partitions is assocd. with a ferromagnetic member such as a steel ball upon which a magnetic pull may be exerted for destroying at least part of the partition so that the contents of the cells may mix with each other.

Stable solutions of phenylazodiaminopyridine or derivatives for injection. Wander Gyógyszer- és Tápszergyár R. T. (Dionys Beke, inventor). Ger. 684,977, Dec. 8, 1939 (Cl. 30*h*. 3). The material is dissolved in ethylene glycol or its homologs at a temp. of about 40–50°. The ampoules are filled at this temp., sealed off, heated for an hr. in boiling H_2O or steam, and quickly cooled.

Drying ointments. Reinhard Beutner (to Parke, Davis & Co.). U. S. 2,184,575, Dec. 26. A drying, substantially nonsepg. ointment base capable of being spread as a continuous film upon the skin, comprises a soln., in a volatile solvent, of a film-forming material and a substantially stable suspension, in such soln., of a material insol. therein, one of the materials being a condensation product of a phenol and a member of the group consisting of aldehydes and ketones capable of forming resinous condensates with the phenol, and the other being a condensation product of a urea and an aldehyde, the proportion of solvent and of solid material being such that the prepn. is of plastic, nonflowing consistency.

Use of ozone in preparing antirachitic products. James K. Elderkin and Emil Hofman (to Chemical Products Co. of N. J.). U. S. 2,183,933, Dec. 19. Sprayed milk or other food or food ingredient in which vitamin D potency is to be developed is subjected to the action of ozone as an antirachitic activating agent.

Ascorbic acid. E. Merck Chemische Fabrik (Otto Zima, inventor). Ger. 684,725, Dec. 4, 1939 (Cl. 12*o*. 21). Addn. to 676,011 (*C. A.* **33**, 6530[4]). In place of diacetone-2-keto-1-gulonic acid, as in Ger. 676,011, other methylene ether derivatives of 2-keto-1-gulonic acid are treated with concd. HCl and the resulting ascorbic acid is sepd. from the reaction mixt.

Vacuum distillation of oils containing fat-soluble vitamins. Kenneth Claude Devereux Hickman (to Kodak Ltd.). Brit. 508,469, June 27, 1939. See U. S. 2,180,356 (*C. A.* **34**, 1823[6]).

Vitamin B_6-protein preparation. I. G. Farbenindustrie Akt.-Ges. (Richard Kuhn and Gerhard Wendt, inventors). Ger. 684,975, Dec. 8, 1939 (Cl. 30*h*. 2). Plant or animal substances contg. vitamin B_6 are extd. at a temp. not exceeding approx. 50° and the ext. is treated in known manner for the sepn. or concn. of protein.

Unsaturated dimethylpolyhydrocyclopentanophenanthrenecarboxylic acids or their derivatives. N. V. Organon. Dutch 47,316, Dec. 15, 1939. Unsatd. α-(dimethylpolyhydrocyclopentanophenanthrene)propionic acid or its derivs. are treated with Grignard reagent, acylated, treated with halogen or hydrogen halide, oxidized preferably by CrO_3, freed from halogen or halide and saponified. E. g., to the Grignard soln. from 8 g. Mg and 45 g. PhBr in ether there is added 10 g. 3-acetoxy-$\Delta^{5,6}$-bisnorcholenic acid (m. 235°). Toluene is substituted for ether and heated for 2 7 hrs. on a water bath, the Mg compd. decomposed with ice-cold acid and the liquid treated with steam. The residue is taken up in ether, evapd. to a clear yellow sirup, taken up in 40 cc. dry pyridine and allowed to stand for a day at 20° with 10 g. Ac_2O, then poured in water and freed from pyridine and Ac_2O. The remaining oil is crystd. by rubbing with petr. ether and recrystd. from EtOH, 7 g. needles first m. 176°, second m. p. 186–188.5°. To 7 g. of this acylated diol in ether is added 2.12 g. Br_2, the ether evapd. and the residue dissolved in 500 cc. AcOH; to the soln. at 45–55° is added with stirring a soln. of 15 g. CrO_3 in 15 cc. water + 100 cc. AcOH dropwise then kept for 2–3 hrs. at this temp. After cooling the reaction product is taken up in ether, 5 g. Zn powder and 50 cc. AcOH are added. After ether evapn. the product is shaken for some time on a water bath; after cooling the Zn and bromide are filtered off and the product is taken up in ether. After repeated washing with H_2O, the ether soln. of 3 acetoxy-$\Delta^{5,6}$-etiocholenic acid is shaken out with 10% NaOH and the Na salt pptd. This is centrifuged, acidified and dissolved in ether. After drying with Na_2SO_4 the ether is evapd. and the residue crystd. from AcOH. The 3-acetoxy-$\Delta^{5,6}$-etiocholenic acid, needles or leaflets, m. 243.5° (Me ester, 153–4°) is obtained in 0.5 to 1 g. yield. With alc. alkali the product can be saponified to 3-hydroxy-$\Delta^{5,6}$-etiocholenic acid, m. 280–8°; methyl ester m. 181–3°. It is an important intermediary in hormone synthesis.

Dihydrofollicle hormones and analogs and their derivatives. Walter Schoeller (to Schering Corp.). U. S. 2,184,167, Dec. 19. A process for the manuf. of dihydrofollicle hormone and its unsatd. analogs, dihydroequilin and dihydroequilenin, and their derivs. comprises gradually introducing a soln. of follicle hormone, equilin, equilenin or their 3-derivs. into an aq. suspension of sugar and yeast, allowing the mixt. to ferment, thereafter extg. the mixt. by means of an org. solvent wherein the partially hydrogenated hormone is sol., and isolating the hormone from the ext.

Saturated and unsaturated derivatives of pregnan-3-ol-20-one. N. V. Organon. Dutch 47,451, Dec. 15, 1939. Derivs. of pregnan-3-ol-20-one substituted in position 21 by OH, acyloxyl, alkoxyl or halogen and possibly substituted in the ring by one or more such groups as hydroxyl, acyloxyl, alkoxyl, halogen, ether or oxide O are prepd. from a satd. or an unsatd. substituted etiocholanic acid by converting it to the acid chloride while protecting free OH groups by acylation or etherification, converting this with diazomethane and treating the reaction product with acids or salts. The protected OH groups are subsequently liberated by saponification. By using excess diazomethane the 21-diazo compd. can be caused to react with aq. inorg. O acids or org. sulfonic or carboxylic acids. Also the 21-diazo compd. can react with anhyd. org. carboxylic acids at temps. between 40° and 120°, or with hydrogen halides, and this in turn with salts of org. carboxylic acids. Other details are discussed.

Derivatives of corticosterone, etc. Tadeus Reichstein and Emil Schlittler (to Roche-Organon Inc.). U. S. 2,183,589, Dec. 19. Therapeutic compds. are produced by esterifying suprarenal cortical hormones such as corticosterone with reagents such as Ac_2O, butyryl chloride, palmitic acid chloride, Na and Me butyrates, benzoyl chloride, succinic anhydride, phthalic anhydride, chloro-

sulfonic acid, bromopropionic acid, nitrobenzoic acid, etc. (various examples with details being given). Cf. *C. A.* **33**, 8925[7].

Perfume compositions. Walter C. Meuly (to E. I. du Pont de Nemours & Co.). U. S. 2,184,526, Dec. 26. Perfumes are prepd. contg. the hemiacetal of *p*-isopropyl-α-methylhydrocinnamaldehyde together with an aromatic or terpene alc. such as *p*-isopropyl-α-methylhydrocinnamyl alc.

Germicidal and antiseptic compositions. Mahlon J. Rentschler and Donald B. Bradner (to Hamilton Laboratories, Inc.). U. S. 2,183,493, Dec. 12. A soln. of a phenylmercuric salt such as a soln. of phenylmercuric borate in dil. alc. is used with a tribasic inorg. acid such as boric acid in a greater proportion as a stabilizing agent to inhibit deterioration by age.

Depilatory. E. Didier. Belg. 429,447, Aug. 31, 1938 A mixt. of ZnO (17%), sol. ketone (60%) and insol ketone (23%) is spread in the plastic state on a flexible support such as paper, film or fabric.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

SYMMES

Manufacture of nitric acid by the Fauser process, with the use of stainless steel turbocompressors. Ch. Berthelot. *Génie civil* **115**, 381-3(1939). -A review. Recent progress in Cr-Ni steels has permitted the removal of important quantities of the water vapor after leaving the combustion chamber. Ann Nicholson Hird

Contact sulfuric acid manufacture. XX. The vanadium oxide catalyst prepared in Japan. Raisaku Kiyoura. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 315(1939), cf. *C. A.* **34**, 5919.—Matui's catalyst, prepd. for industrial use, gives conversion yields similar to those obtained with imported contact masses. **XXI. Accumulation of iron sulfate on the catalytic mass.** *Ibid.* 315.—During prolonged use, the V catalyst becomes choked with Fe sulfate powder and the resistance to gas flow increases, but the conversion efficiency of the catalyst, after removal of most of the Fe sulfate, is only slightly reduced, this slight reduction probably being due to clogging of the pores of the catalyst. **XXII.** Mototaro Matui, Raisaku Kiyoura, Hirosi Morita and Teiti Sawai. *Ibid.* 329.—The activity of pptd. Cr_2O_3-SnO_2 catalysts (cf. Neumann, *C. A.* **23**, 934; Adadurov, *C. A.* **29**, 1945[3]) depends, to a great extent, on the method of prepn. SiO_2 gel and diatomaceous earth, when used as carriers, decreased the activity of the catalyst. **XXIII. The crystalline state of potassium sulfate in the V_2O_5-K_2O-SiO_2 catalyst.** Raisaku Kiyoura. *Ibid.* 377-8.—Catalyst prepd. by soaking calcined diatomaceous earth (in tablet form) with aq. K_3VO_4 and treating at 450-500° with gas contg. SO_2 contains cryst. K_2SO_4. The crystals become larger when the catalyst is used at higher temps. and for long periods; for example, at 600° after 7000 hrs. they formed large needles, while the crystals of V_2O_5 or $VOSO_4$ remained in a very finely divided state. **XXIV. Relation between the catalytic activity and the crystal growth of potassium sulfate in the V_2O_5-K_2O-SiO_2 catalyst** *Ibid.* 378-9.—The crystal size of the K_2SO_4 present in the catalyst has extremely little effect on the activity of the catalyst. This is not in accordance with Neumann's explanation of the promoting action of Na_2SO_4 on V_2O_5-SiO_2 catalyst. George Ayers

The use of waste calcium sulfide for producing sulfuric acid. S. N. Ganz. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 42-4(1939). -When CaS is heated to 500° in an air stream, SO_2 is formed. H. M. Leicester

Installations for the manufacture of nitrogen fertilizers and fuming sulfuric acid at San Guiseppe di Cairo (Italy). Ch. Berthelot. *Génie civil* **113**, 29-34(1938).—This assemblage of plants is described with a graph, 3 diagrams and 4 photographs. It is one of the most important installations of the Fauser process in the world. The group comprises not only the coke ovens, but all the plants needed to produce the finished by-product. A. N. Hird

The replacement of lead by iron condensers. G. S. Grigor'ev. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 44-6 (1939).—Details of the use of Fe condensers in H_2SO_4 factories are discussed. H. M. Leicester

Recovery and utilization of magnesium compounds in magnesium mud precipitated from brine liquor. I. Manufacture of anhydrous magnesium chloride. T. Nisikawa, T. Okuno and N. Nakao. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 318-19(1939); cf. *C. A.* **33**, 6003[8].—Cl gas is passed at the rate of 0.56 l./min. through a mixt. of 80 g. MgO (prepd. from the magnesium mud in a salt field), 115 g. NaCl, 147 g. KCl and 22 g. coke maintained at 700°, with production of $MgCl_2$ (and CO_2). The addn. of Fe_2O_3 to the mixt. increases the yield. George Ayers

Potassium, sodium and magnesium salts in the European part of the U. S. S. R. S. I. Vol'fkovich. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 1-2(1939). H. M. L.

Preparation of pure alumina from Manchurian clay VII. Preparation of aluminum hydroxide by the treatment of ammonium alum with ammonia under ordinary pressure. Tuyosi Arimori. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 355(1939); cf. *C. A.* **33**, 4385[8]. -In continuation of a previous paper (cf. *C. A.* **33**, 3537[9]), $Al(OH)_3$ ppt. from cryst. alum with NH_4OH under ordinary pressure contains less sulfate than ppts. obtained by treatment of the same alum with ammoniacal solns. satd. with $(NH_4)_2SO_4$. Dehydration of the alum before this treatment is unnecessary. The $Al(OH)_3$ obtained with concd. NH_4OH (more than 5 *N*) is cryst.; its purity and properties are definitely influenced by the amt. of NH_4OH used and by duration of treatment. **VIII Preparation of aluminum hydroxide by the treatment of ammonium alum with ammonia under pressure.** *Ibid* 355-6.—Small crystals of alum, spread over concd. NH_4OH, are neutralized quickly in the hot state under pressure before the alum dissolves in aq. NH_4OH. Pure, large cryst. $Al(OH)_3$ is obtained. With weak NH_4OH (under 3 *N*), the $Al(OH)_3$ obtained is granular. To prep. the cryst. form, the amt. of NH_4OH used must be 1.5 times or more the chem. equiv. and NH_4OH must be more than 1 *N*. Reaction temp., time and fineness of the alum are important. The so-called cryst. $Al(OH)_3$ obtained may be the pseudo-cryst. form, whose single crystal is very small, but whose aggregation has the same size as that of single crystal of the original alum. M. McMahon

Methods of manufacturing alumina from highly aluminous materials of Korea, Manchuria, and North China Syoitiro Nagai. *Japan. Ceram. Assoc.* **47**, No. 559, Suppl. 37-48(1939).—Various methods, mostly patented by N., of extg. Al_2O_3 from highly aluminous materials produced in Korea, Manchuria and North China are given. These clays consist of kaolinite and diaspore. A linear relation exists between their Al_2O_3 content and sp. gr. Al_2O_3 as diaspore can be extd. almost completely by treatment with NaOH soln. in an autoclave. Clays contg. over 60% Al_2O_3 are melted with CaO in an elec. furnace to give a melt rich in tricalcium aluminate, then treated with a mixed soln. of alkali carbonate and caustic alkali. The same clays, and those less rich in Al_2O_3, are fired, together with Na_2CO_3 and limestone, in a rotary kiln. About 95% of Al_2O_3 can be obtained by treating the powd. product with H_2O and dil. alkali soln. Korean nephelite is best treated with concd. H_2SO_4, or may be calcined with Na_2CO_3 and limestone, and the pulverized product treated with H_2O and alkali carbonate soln. S. K.

Dehydration of ammonium sulfate. A. Thau. *Glückauf* **75**, 768-71(1939).—An English belt drier is described. L. P. Rockenbach

The lime-chlorine system in the preparation of calcium hypochlorite. F. W. O'Neil and J. D. Rue. *Paper Trade J.* **109**, No. 23, 39-42(1939).—Potentiometric

studies were made during progressive chlorination of soln. contg. 16, 32 and 52 g. per l. of $Ca(OH)_2$ at 0-40°. During chlorination, pH decreased rather slowly at first, with a very rapid increase in available Cl; further chlorination beyond a pH of 11.2 caused a very rapid decrease in pH and only a slight increase in available Cl; when the $Ca(OH)_2$ was chlorinated below pH 8, the loss of available Cl was very rapid, and above 10° the loss was greater than that which could be maintained by addn. of Cl, and on standing the soln. lost practically all of its available Cl. $Ca(OH)_2$ chlorinated to the "3-sec. flash" of phenolphthalein (corresponding to pH 11.2) produced a bleach liquor that was stable for at least 48 hrs. A. P.-C. 1

The influence of the method of hydration on the properties of hydrated lime. A. Ceresetо and A. Rio. *Atti. X° congr. intern. chim.* **4**, 635-42(1939)(in Italian). -The hydration of CaO, under varying conditions of atm. of H_2O, fineness of CaO and temp. of hydration, and the resultant plasticity, adhesion and stability were studied. The most favorable conditions were low temp., slight excess of H_2O over the theoretical amt., and max. surface. Five tables and 2 references are given. Henri Marc 2

Lowering the loss of (sodium) sulfite in the process of its recovery from waste products of the organic chemical industry. V. S. Kaminskiĭ and V. S. Seredkina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 518-19(1939).- The loss of Na_2SO_3 by oxidation in the process of concn. can be reduced from 15-20% to 3-4% by adding 2.5-5 g. of crude hydroquinone to 1 ton of the soln. Na_2SO_3 is not oxidized in the process of crystn. from the treated concentrates. Chas. Blanc 3

The work of the mechanical salt-cake furnace. A. M. Gmelling. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 31-4 (1939). App. for prepg. Na_2SO_4 from NaCl and H_2SO_4 is criticized. H. M. Leicester 4

Conversion of methane into hydrogen and carbon monoxide Process of the Société Belge de l'Azote at Renory. Ch. Berthelot. *Genie civil* **115**, 461-4(1939); cf. *C. A.* **33**, 8562⁶.—A continuous catalytic process recently developed, which works under atm. pressure, is reviewed with 2 diagrams. Ann Nicholson Hird 5

Conditions for the simultaneous preparation of technically pure oxygen and nitrogen from air. M. B. Kal'manovich and I. P. Ishkin. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 12-15(1939).—The operation of an app. with 2 rectifying columns is described, and the points at which fractions rich in A must be withdrawn, to give almost complete sepn. of O and N, are discussed. H. M. Leicester 6

Properties of clay. Ralph E. Grim. *Recent Marine Sediments: a symposium, Am. Assoc. Petroleum Geol.* 1939, 466-95; cf. *C. A.* **33**, 5615³.—An extensive review of the clay minerals, including optical, chem. and dehydration properties, base exchange capacities, lattice structures, distribution, origin, compn. and the relation of phys. properties to mineral compn. One hundred and sixty-one references. George Ayers 7

The chemical composition of the Ordyn gypsums. A. V. Gertakovskiĭ *Trudy Tsentral. Nauch.-Issledovatel. Lab. Kamneĭ Samotsvetov Tr. "Russkie Samotsvety"* **1938**, No. 5, 37; *Khim. Referat. Zhur.* **2**, No. 5, 32(1939).—The dehydrated waste products of the Ordyn gypsums, with a content of foreign elements (mainly Fe) not over 2.5%, are suitable for *medicinal purposes*. W. R. Henn 8

Products of various types of carbon black from natural gases. G. Bruni und T. G. Levi. *Atti X° congr. intern. chim.* **4**, 79-82(1939).—A series of expts. based on an impingement process of producing C blacks is discussed. Flames obtained from burning mixts. of naphthalene or anthracene with coal gas and other combustible gases were used. The influence of various exptl. conditions, such as type and dimensions of the burners and of the gas jets used, height of the flame, ratio of the quantities of vapors of the hydrocarbons and of the combustible gases, resp., was studied. The properties of the different types of C blacks obtained and of the *rubber* samples prepd. therefrom were investigated. The quality of the material was very high. The production of C black from C_2H_2 by a process of impingement was studied. The rubber sample prepd. from this C shows a very high degree of resistance to abrasive action. The tech. problem of prepg. high-grade C black from natural gases may be regarded as solved. Robert Simha 9

System Na_3PO_4-Na_2CO_3-H_2O (Kobe, Leipper) **2**. New ways of obtaining and of employing Tl (Drescher) **9**. Protection of Bakman app. from corrosion [app. for chlorinating CaO] (Khanin) **9**. Electrothermal decompn. of carbonaceous liquids [manuf. of C black] (Brit. pat. 508,509) **4**.

Hydrocyanic acid. Charles R. Harris (to E. I. du Pont de Nemours & Co.). U. S. 2,184,062, Dec. 19. HNO_3 is treated with an excess of a hydrocarbon, such as CH_4 or C_2H_4, in the absence of a catalyst at 800-1400°, in the presence initially of at least one vol. of water vapor and 2-10 vols. of an inert gas per vol. of NO.

Hypochlorous acid. Solvay & Cie. Belg. 423,470, Oct. 31, 1937. Cl and H_2O are introduced simultaneously at the base of a tower filled with limestone. The liquor passes systematically through the limestone filling of the tower and is discharged through an overflow.

Sulfuric acid. K. M. Malin and I. N. Kuz'minykh. Russ. 51,895, Oct. 31, 1937. Addn. to Russ. 38,626. In the manuf. of H_2SO_4 by the nitrose method, the oxidizing space for nitrogen oxides is connected as a shunt in the path of the gas before the first Gay-Lussac tower.

Sulfur dioxide and phosphate fertilizer. Chemische Werke Albert (Ferdinand Bornemann und Hans Huber, inventors). Ger. 684,735, Dec. 4, 1939 (Cl. 16, 5). Addn. to 681,644. In the simultaneous prepn. of SO_2 and phosphate fertilizer according to patent 681,644, the crude phosphate employed is partially pretreated with H_2SO_4.

Alkaline earth cyanamide. Bayerische Stickstoff-Werke Akt.-Ges. Ger. 684,942, Dec. 8, 1939 (Cl. 12*h*, 9). Addn. to 654,235 (*C. A.* **33**, 2299⁷). In the action of NH_3-CO_2 mixt. upon alk. earth oxides, the flow of the CO_2 and NH_3 is so regulated, that the ratio of the reaction gas added to CO_2 amounts to at least 2 and at most 35%, preferably 5-20%, and that upon an increase of the cyanamide content in the nitrogenized product above 40-50% cyanamide, the CO_2 content of the reaction gas increases to about 50% CO_2.

Salts in large crystals. Soc. belge de l'azote et des produits chimiques du Marly, Soc. anon. Belg. 429,512, Sept. 30, 1938. In the process of Belg. 428,872 for pptn. of impurities as arsenates, any H_3AsO_3 present is oxidized by means of O-N in the presence of I or iodides as catalyst.

Aluminum magnesium silicate. Herbert Witzenmann (Ludwig Stuckert, inventor). Ger. 684,941, Dec. 8, 1939 (Cl. 12*i*, 38). Addn. to 458,475. Instead of $MgCl_2$ in the fusion with quartz, Al_2O_3, feldspar and fluorspar, other similar Mg salts are employed, such as $MgCO_3$, $MgSO_4$, MgC_2O_4, which (if necessary under the application of reducing agents) easily yield magnesium oxide.

Inhibiting dusting of arsenious oxide. Melville F. Perkins (to American Smelting and Refining Co.). U. S. 2,183,337, Dec. 12. As_2O_5 is mixed with As_2O_3 (suitably in a proportion of about 0.06-0.1% of the As_2O_5) to absorb moisture so as to inhibit dusting but insufficient to impart any substantial sensible dampness.

Purifying boron carbide. I. G. Shafran. Russ. 52,084, Oct. 31, 1937. Addn. to Russ 50,979 (*C. A.* **33**, 3979⁷). The boron carbide is heated at a temp. below redness with molten caustic until NH_3 is no longer evolved. The melt is then washed to remove the caustic, boiled in HCl, and dried.

Calcium metaphosphate. Harry A. Curtis. U. S. 2,184,287, Dec. 26. A continuous process of making Ca metaphosphate involves mixing rock phosphate and liquid metaphosphoric acid, heating the mixt. to effect reaction with formation of fused Ca metaphosphate, and recovering and returning to the reaction zone that part of the metaphosphoric acid which does not initially react

with the rock phosphate and is volatilized. Cf. *C. A.* **34**, 5828.

Cupric hydroxide. New Process Rayon, Inc. Brit. 508,495, June 30, 1939. A suspension of CuS in a soln. of an inorg. alk. material other than NH_3, e. g., the hydroxide or carbonate of an alkali metal, is aerated to form $Cu(OH)_2$, the sol. alkali being present, preferably, in excess of that required to form a thiosulfate with the S content of the CuS employed. The CuS may be an ore or that recovered by addn. of a suitable sulfide to an alk. pptn. liquor obtained in the production of regenerated cellulose by the cuprammonium process. Cf. *C. A.* **33**, 8367.

Ferric sulfate. Theodore V. Fowler and Henry F. Merriam (to General Chemical Co.). U. S. 2,184,419, Dec. 26. For making anhyd. $Fe_2(SO_4)_3$, solid $FeSO_4$ is furnaced with H_2SO_4 in amt. not less than 30 and not more than 60% in excess of that theoretically required to oxidize the $FeSO_4$ to $Fe_2(SO_4)_3$, at temps. of 275-450°, and furnacing and agitation are continued to effect such oxidation and to form a substantially dry anhyd. product.

Recovery of sodium tetraborate from borate ores. Plato Malozemoff, Merrill W. MacAtee and Miles W. Kirk (to Pacific Coast Borax Co.). U. S. 2,184,558, Dec. 26. A borate ore contg. Na tetraborate and minerals insol. in water, such as Baker ore, is mixed in finely divided condition with a satd. soln. of Na tetraborate, and the pulp is then subjected to a froth-flotation treatment in the presence of a reagent, comprising $BaCl_2$ and a fatty acid, such as oleic acid, having a preferential affinity for the Na tetraborate.

Reactive thorium oxide. Chemische Fabrik von Heyden Akt.-Ges. (Richard Muller and Harry Lee, inventors). Ger. 684,723, Dec. 4, 1939 (Cl. 12*m*, 9). See Fr. 828,334 (*C. A.* **33**, 3304).

Recovery of carbon dioxide from gases. Gustave T. Reich. U. S. 2,183,324, Dec. 12. Gases contg. CO_2 are brought into contact with a soln. of alkali carbonate satd. with alkali bicarbonate, whereby a suspension of alkali bicarbonate is formed; this suspension is heated to dissoc. not more than the alkali bicarbonate in suspension to alkali carbonate and CO_2, while maintaining the alkali carbonate in soln., and the soln. contg. alkali carbonate satd. with bicarbonate is returned for treating gases contg. CO_2. Cf. *C. A.* **33**, 3120.

Mixture of hydrogen and carbon monoxide. Soc. internationale des carburants "Brevetés Consalvo" S. A. Holding. Belg. 426,221, March 31, 1938. ZnO, CO_2 and H_2O are treated with excess of CaC_2. The CaC_2 is subsequently regenerated in the same chamber.

Iodine from seaweed. Thomas Dillon, Donal T. Flood, Vincent C. Barry and Pádraig O'Muineacáin. Brit. 508,715, July 5, 1939. I and other substances are removed by digesting seaweed with a weak aq. soln. of acid, sepg. the acid ext. liquor after the digestion and treating it, preferably hot, with insol. Cu compds., e. g., CuCl, Cu_2O, that combine to form I-Cu compds., which are sepd. by filtration or sedimentation. The remaining liquor may have a further quantity of acid added as and when required and be used again repeatedly. K and other salts and org. substances, e. g., mannitol, may be recovered by any suitable means from the remaining liquor after such repeated use. The remaining liquor may be neutralized and evapd., the residue being used as a *fertilizer*.

Preventing salt from hardening or caking. Marnell Segura (to Jefferson Island Salt Mining Co.). U. S. 2,183,173, Dec. 12. The salt is treated with an aq. soln. of sorbitol in an amt. of 0.02-5.0% the wt. of the salt.

Sintering fluorspar. Reed W. Hyde. U. S. 2,184,078, Dec. 19. Finely divided fluorspar is mixed with a moistened inorg. plastic cementing material and the mixt. is formed into pellets which are sintered in a shallow bed with a down blast of air.

Carbon black. I. G. Farbenindustrie A.-G. Brit. 508,594, July 4, 1939. C black, with or without HCN, is sepd. from gases obtained in the production of C_2H_2 by the thermal splitting of hydrocarbons by quenching the gases with H_2O and then washing the moist gases with H_2O at an elevated temp., e. g., 50-80°. The washing is preferably conducted at a temp. such that, apart from HCN, as little as possible of other gas constituents, in particular C_2H_2, is dissolved, e. g., at 80°.

Improving carbon black. Walther H. Grote (to United Carbon Co.). U. S. reissue 21,302, Dec. 19. A reissue of original patent No. 2,066,274 (*C. A.* **31**, 1171).

Activated carbon. I. A. C. Società per l'Industria applicata del caoutchouc e per materiali protettivi ed antigas. Ger. 684,774, Dec. 5, 1939 (Cl. 12*i*, 33). Powd. peat, sawdust or similar materials are impregnated with a soln. of $ZnCl_2$ and rapidly heated to 180°; simultaneously $ZnCl_2$ in about 2.5-3.0 times this amt. is dissolved in the least possible amt. of H_2O and brought to boiling. As soon as the soln. temp. reaches 200-210°, the powd. peat is added and the entire mass is quickly brought to about 240°. During the mixing the reaction mass is heated to 300° and at this temp. no further heat is applied but the influence of the air causes a self-generation of heat to 400°. The mass is allowed to cool.

19 GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Glass as a chemical engineering material. II. Filters and insulation. R. Quarendon. *Ind. Chemist* **16**, 61-2 (1940); cf. *C. A.* **34**, 1827. E. H.

Organic glass. F. H. Zschacke. *Glashutte* **69**, 810-11 (1939).—The outstanding properties of org. glass afford wide fields for its application. The org. "Plexi-glas" is superior to silicate glass in transparency, permeability to ultraviolet rays, transverse strength, ease of working, shatterproofness and lightness; it has superseded silicate glass in airplanes and vehicles though it has not yet been sufficiently developed for use for kitchen and household ware. M. V. Condoide

Significance of the mineralogical composition of quartz sand when glass is melted. M. A. Bezborodov, A. C. Zaporozhtzwa and I. G. Moiseeva. *Stekol'naya Prom.* **15**, No. 7, 26-9 (1939). (1) When quartz sands are evaluated it is necessary to know not only their chem. and granulometric compn., but also their mineralogical compn. (2) Because of the difficulty of dissolving sep. minerals, particularly zircon and cyanite, it is of the greatest importance to observe the melting of the glass so that incompletely melted components will not penetrate into the working zone, and will not be dissolved later by the glass mass. (3) Besides the minerals mentioned, experience shows the difficult assimilation of small lumps of kaolin. (4) Iron inclusions in the form of particles which are introduced into the melt in one way or another are also difficult to digest. (5) It is necessary to use a polarization microscope for a thorough study of stones present in glass and their mineralogical compn. M. V. Condoide

Use of sandstone with a high alumina content in the production of pane glass by the Fourcault method. Yu. Ts. Vinogradov and S. V. Rodin. *Stekol'naya Prom.* **15**, No. 7, 8-13 (1939).—The compn. of sandstone and problems confronting its use for glass manufd. according to the Fourcault method are dealt with. M. V. Condoide

Zinc oxide in the glass industry. L. Springer. *Sprechsaal* **73**, 16-17 (1940).—Two grades of com. ZnO, contg., resp., 8.4 and 4.7% PbO and 0.06 and 0.02% FeO, were used in expts. to replace CaO, BaO and PbO in part or completely. ZnO had little or no effect on the fusibility of the glass. If oxidizers, e. g., nitrates or arsenic, were used no difference in color was produced by ZnO. Up to 9% ZnO in lead glass and 8% ZnO in lead-free glass did not cause devitrification. The resistance to chem. corrosion was improved by ZnO. J. M. Noy

Glasses containing cobalt oxide. Kiuzo Huwa. *J. Japan. Ceram. Assoc.* **47**, 189, 228-30(1939).—In 3 series of glasses, consisting of 72% silica, 12% lime, and 16% alkali, whose contents of lime were substituted by 0.01 to 12% of Co oxide the density of each series of the glasses increased with an increase of CoO content. Obtained values of density agreed well with those calcd. when d. of CoO in glass was assumed to be 6.4 for 2 series and 8.6 for another. Coeff. of thermal expansion decreased with an increase of CoO content. Numerical values of the coeff. agreed well with those calcd. when 2.4 was used as const. for CoO in 2 series and 4.0 in the other. The softening temp. was lowered with an increase of CoO. The temp. at which the specific resistance of glass becomes 1500 ohms./cm. tended to be lower with an increase of CoO. The soly. of alkali in water increased slightly on the introduction of CoO; this shows a max. when the contents of lime and CoO were equal. The soly. in the acid was not affected by the substitution. The soly. in sodium carbonate soln. was similar to that in water but the effect was far lighter. The soly. in NaOH soda soln. was slightly increased by an increase of CoO. S. Kondo

Sodium fluosilicate in the glass batch. F. H. Zschacke. *Glashutte* **69**, 785 6(1939).— Na fluosilicate is excellent for the fining of brown glass colored with sulfide, green glass fused with sulfate, and certain colored glasses fused without sulfate or saltpeter, white hollow glass and certain "tube" glasses which must not contain As. Na fluosilicate is a salt obtained in the prepn. of superphosphate and is relatively pure and free from iron and does not vary in compn. Because of its high F content it is a more effective fining agent than fluorspar and its decompn. into the volatile SiF_4 (the fining agent in the batch) and NaF (which is destroyed at higher temps. and does not cause opacification) takes place at lower temps. than that of fluorspar. The decolorizing action of the fluorides is derived from the formation of iron fluoride which is volatile at fusion temps. (1000°), and also from the formation of the colorless complex and double salts. The amt. of silicic acid which volatilizes lies within the weight error for the batch. Na fluosilicate cannot be used in place of borax. M. V. Condoide

Grog masses for glass pots and tanks. Oskar Lecher. *Glashutte* **69**, 529 30(1939).—The compn. of masses for pots and tank block and practical experience in meeting the action of the fused glass on grog linings in the past few years in Germany are discussed. In tanks grog with high alumina content was found to resist the molten glass better than block with a high silicic acid content because the protective layer formed between the glass and the block is more viscous and adheres better and is therefore not as easily absorbed by the glass in the form of streaks and stones. Special care in the working and firing of masses is required to prevent the formation of cracks in the block because they facilitate the penetration of the glass into the block and hasten disintegration. The compns. of German tank block and pot clays are given. M. V. Condoide

Action of arsenic on the coloring and decolorizing of glass. I. L. Springer. *Glashutte* **69**, 497–9(1939).—Arsenic acts on color oxides sometimes as oxidizer and sometimes as reducer: (1) Arsenic oxidizes iron oxide. (2) Mn oxide is weakened by As. (3) S. found that As caused a brown-violet color produced by Ni oxide in a soda lime glass to disappear. No action was observed on a Co blue glass. (4) Arsenic displaces the yellow coloring of Cr compds. toward green. (5) Arsenic has a reducing action on Cu oxide. Arsenic decolorizes Ag in a lime crystal glass, but has no effect on a lead glass; it deepens the yellow color when introduced into another glass. (6) Arsenic weakens, for the most part, the effect of Se according to S. and others. (7) S and C compds. are oxidized and become colorless through the effect of As. (8) No As is used with rare earths. The question of the effect of As on the fading of colored glasses in light is complex and depends on the amt. contained and on the other constituents, but the presence of Pb oxide tends to counteract fading. **II.** *Ibid.* 633–4.—Special studies were made of the action of As on pyrolusite (MnO_2) and iron oxide, because it is here that the two-sided nature of As, viz., sometimes reducing and sometimes oxidizing, appears. The tests are described and results are given as follows: (1) Pyrolusite with As, but without saltpeter gave varying colors, often directly opposite, in an oil furnace. In an elec. furnace small or large amts. of As always weakened the color. The addn. of saltpeter (also in an oil furnace) gave great stability to the coloring but at the same time the As weakened the color tone in proportion to the amt. added. (2) Pyrolusite with the addn. of As and sulfate: In an oil furnace 2 parts sulfate completely destroyed the coloring with small or large addns. of As. In an elec. furnace sulfate alone did not weaken the color, but with the addn. of As the color was weakened. (3) Fundamentally, As acts as a reducer. But if large quantities of As are added to a batch contg. Se compds. and either iron oxide or pyrolusite, the As may also act as reducer in the first stage of fusion. On the other hand, it can also take up O, especially when saltpeter is also present (formation of As_2O_5 oxide) and in the fining of glass it becomes an oxidizer. Whether this explanation of the oxidizing action of As should be accepted, or the formation of colorless iron compds. is the cause, remains uncertain. M. V. C.

Effect of the chemical composition and of the coloring agents on the properties of selenium ruby glass. S. M. Berekhovskikh. *Stekol'naya Prom.* **1938**, No. 12, 25–9; *Khim. Referat. Zhur.* **2**, No. 5, 86–7(1939). -Increase of the ZnO content in glass intensifies the red color; with an increase of ZnO, the content of alkalies should be increased. The content of ZnO in glass should not be lower than 3% for pressed articles. An addn. of up to 10% of B_2O_3 increases the red color of glass. B_2O_3 also increases the clearness of glass; it is best introduced as cryst. borax. Replacement of K_2O by Na_2O diminishes the red color. Na glass "fades" more at high temps. than does K glass. The content of alkalies should not exceed 15 20%. Decreasing order of the intensification of the color produced by the oxides of Se and Cd is ZnO, B_2O_3, P_2O_5, K_2O, Na_2O, Al_2O_3, SiO_2, BaO, CaO and MgO. Tartaric acid and SrO should be introduced in amts. of 0.5 0.8% of the wt. of glass. The introduction of Sb should be avoided. W. R. Henn

Variations in absorption of selenium colored glass as a function of temperature. Jean Escher-Desrivières and Yves Godron. *Compt. rend.* **210**, 215–17(1940).—The variation in absorption by an orange Se glass was examd. between 10° and 360° for light of λλ 5700 to 6500 A. Transmission decreases with temp.; thus for light of λ 6200 it is 80% at 10°, 39% at 267° and 2% at 360°. For light of λ 5900 the corresponding figures are 63, 47 and 13%. The curves of transmission against λ for various temps. are approx. parallel. (Cf. Luckiesh, *C. A.* **13**, 3291.) C. A. Silberrad

Melting glass of different compositions in a pot furnace. K. V. Manzhurnet and V. E. Stepanov. *Stekol'naya Prom.* **15**, No. 7, 14(1939).—Four kinds of glass for glass pipes and glass rods were melted simultaneously in a 12-pot furnace fired with unpurified gas. M. V. Condoide

Tank furnace with circulation for the production of chemical glass. M. A. Bezborodov. *Stekol'naya Prom.* **14**, Nos. 8-9, 25–7(1938); *Chimie & industrie* **41**, 1122.—The furnace provides for heat regeneration, with transverse movement of the flame, and is heated by means of 2 pairs of burners. The tank is shallow (0.8 m.) which permits reduction of the inert layer to a min. For a given quality of product, this furnace is more advantageous than pot furnaces. A. Papineau-Couture

Heat flow in a glass furnace. Otto Th. Koritnig. *Glashutte* **69**, 548–51(1939).—The detn. of the quantity of heat transferred to the melt in pot furnaces and also in tank furnaces is difficult because 3 different temps. exert an influence on the melt: (1) the variable heat from the fuel source, (2) the reflection from the furnace walls and ceiling and (3) the heat of the melt itself. Temp. measurements with a pyrometer may not be correct because numerous factors as the position of the instrument with reference to the gas flow, the conditions at the beginning

and ending of temp. measurement, and the duration of temp. measurements condition the accuracy of measurements. Equations are given for the theoretical calcn. of heat loss by absorption of heat by furnace masonry and radiation; heat-transference (3 types); emissive power of walls and charge; and the heat-penetration figure. Since these factors depend on the type of fuel, excess of air for firing, temp. of the heating gases, type of furnace masonry and size of the furnace, the difficulty of accurately detg. the total heat transference is understood. The theoretical calcns. do have a practical value, however, for the study of improving furnace construction and the comparison of furnaces fired with different types of fuel. M. V. C.

Annealing muffle for hollow glass. Otto Ehinger. *Glashutte* **69**, 822-4(1939).—A gas-heated well-insulated muffle in "channel" form for annealing gold borders, markings and printing which can be built inexpensively in any plant is described. Gas firing is very economical and can be regulated; it gives more uniform heat and the charge is not coated. The burner in the furnace is arranged over the muffle. In order to anneal 5 6000 glasses in 8 hrs., the muffle (7500 mm. long) is divided into 3 zones: preheating (2500 mm.), annealing (3000 mm.), cooling (2000). The annealing muffle is divided into 6 parts of 500 mm. length. The interior width of the channel is 600 mm. M. V. Condoide

Dielectric loss of glass at high frequencies. H. Thurnauer and A. E. Badger. *J. Am. Ceram. Soc.* **23**, 9-12 (1940).—Power-factor measurements at frequencies of 100, 500, 1500 and 5000 kilocycles were made on a series of Na_2O-CaO-SiO_2 glasses and on another series starting with a base glass contg. Na_2O 17.4, CaO 10.1 and SiO_2 72.5%, to which 0.030 gram-atom of various elements, in the form of oxide, was added. In the 1st series the power factor for all glasses decreased with increasing frequency and increased markedly with increase in Na_2O content. In the 2nd series the power factor decreased with increasing frequency; it increased with addns. of Zr, Na and Al oxides, and decreased with addns. of the oxides of Si, V, Zn, Mg, B, Ti, Co, Ca, Ce, Ni, Mn, Fe, Ba, Pb, Li and K. C. H. Kerr

Optical constants of glasses. Hans Schulz. *Glashutte* **69**, 620-30, 653-5(1939). The optical consts. of glasses are better for characterizing their type than other values such as the mech. properties of tensile strength, resistance to pressure, density, etc., because they can be detd. with greater accuracy by simple means and permit certain conclusions to be drawn regarding the compn. of the glass. The problem of the relationship between the optical consts. and the compn. of glass is dealt with in detail and the work of other investigators on this subject is summarized. A table gives values for optical consts. for glasses of the new Schott catalog No. 5858. The work of E. Zschimmer, F. E. Wright, H. Mees and H. Karmaus and others and expts. on the effect of increasing addns. of certain constituents in the glass (PbO), and a comparison of calcd. and measured values for the index of refraction and the effect of the infrared and ultraviolet absorption fields are discussed. Conclusion: A simple relationship between optical consts. and compn. can be found only after more exact values of a greater no. of glasses of known composition can be detd. in one larger wave-length interval; the measurements so far obtained are insufficient. M. V. Condoide

Effect of time and temperature on accelerated chemical durability tests made on commercial glass bottles. Frank R. Bacon and O. G. Burch. *J. Am. Ceram. Soc.* **23**, 1-9(1940).—Tests made of chem. durability on both crushed samples and bottle surfaces of a variety of com. glass-bottle compns. show the difficulties in attempting to correlate accelerated tests with the actual performance toward various solns. under service conditions. Results thus far indicate that the value of accelerated tests conducted with distilled H_2O as a leaching medium is questionable as an aid in predicting resistance of various glass compns. to neutral solns. at room temp. C. H. K.

The specific gravity of the ternary glasses CaO-Na_2O-SiO_2 at high temperatures. VI-VIII. Ikutaro Sawai and Syukiti Inoue. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 331-2(1939); cf. *C. A.* **33**, 8371[1].—Sp. gravities of glasses in the region SiO_2 70%, CaO 8-13%; SiO_2 71%, CaO 8-12%; and SiO_2 72% and CaO 10-13% were detd. at temps. ranging from 25 to 1200°. The graph shows the interrelationships of temp. and sp. gr. are not straight lines as was stated in the previous paper. With a const. SiO_2 the sp. gr. generally increases at the various temps. with increasing proportions of CaO. **IX. Measurement of the specific gravity according to Badger and Harman as well as the specific gravity at 1300°.** *Ibid.* Suppl. binding 407-9.—The relations between sp. gr. and temp. for the 3 glasses studied cannot be expressed by straight-line curves as was reported by Badger and Harman (*C. A.* **32**, 8716[7]), but take the form obtained by Haenlein. The sp. gr. at 1300° as reported by B. and H., who used the "bubble-pressure-method," is higher than that reported by the authors, who used Haenlein's method (an arm balance from which is suspended a platinum bead that is immersed in the molten glass, the temp. of which is measured by Pt-Pt + Rh thermoelements). A. W. K.

Surface-tension measurements on molten glass by a modified dipping-cylinder method. C. L. Babcock. *J. Am. Ceram. Soc.* **23**, 12-17(1940). Measurements were made on a series of both calcite and dolomite lime glasses. The temp. range covered was 1100-1400° and the viscosity range was logarithm viscosity 1.65-3.30 (45-2000 poises). The results agree with published data obtained by the max. bubble-pressure method. The temp. coeff. of surface tension is approx. −0.02 dyne per cm. per C°. The surface tension of glass at a particular temp. can be represented as a linear function of compn. on a mol. fraction basis. C. H. Kerr

Joining chromium-iron parts to glass. Schad. *Sprechsaal* **73**, 23-4(1940).—Cr-Fe alloys with more than 15% Cr do not change from the α-structure between room temp. and the m. p. The coeff. of expansion is close to 100 × 10⁻⁷/°C., similar to that of alkali-lime glasses. The thin surface oxide reacts with the glass, forming a stable silicate. A special lathe with two synchronous chucks is used, one holding the metal part, the other the glass part. Some glass is applied first to the heated metal by means of a rod and then the 2 parts are united. Frequently Cu is joined to Cr-Fe parts instead of directly to the glass. J. M. N.

Developments in the field of ceramic engineering during the past ten years. Arthur S. Watts. *Ohio State Univ., Eng. Expt. Sta. News* **12**, No. 1, 19-20(1940). E. J. C.

Notes on clays. IV-V. Mune Utida. *J. Japan Ceram. Assoc.* **47**, 27-33(1939).—Thermal dehydration of Kochite, Otoge pyrophyllite, acid clays (fuller's earths), bentonites, zeolites, a diaspore and a bauxite are reported. Their origin, chem. compn., and phys. properties are discussed. **VI-VII.** *Ibid.* 89-94.—Thermal dehydration curves are given for binary systems, kaolin-bentonite, silica gel-bentonite, silica gel-pyrophyllite, and bentonite-pyrophyllite. Theories regarding clay substance are discussed and the classification of clay minerals based on lattice structure. S. Kondo

Physical and colloidal chemistry of clays. C. G. Albert. *J. Am. Leather Chem. Assoc.* **35**, 25-36(1940).—The surface activity of kaolin particles is discussed. Particle size data are given for some com. kaolins. Penetration of kaolin into sheep leather is illustrated by photomicrographs. H. B. Merrill

Some characteristics of Illinois pottery clay. C. G. Harman. *J. Am. Ceram. Soc.* **23**, 26-9(1940).—Four Illinois pottery clays were studied. They approach ball clay in characteristics. Permeability of the raw clays was detd. by timing the rate of passage of H_2O through a definite layer of clay under standardized conditions; a definite relation was found between permeability thus detd. and the ratio of pore H_2O to shrinkage H_2O. The temp. of inversion of low to high cristobalite in these clays is much lower than is usually accepted for the lower limit of this inversion, because cristobalite is formed at low temps. C. H. Kerr

Present condition of Fukushu clays in Manchuria.

Takehito Sibata. *J. Japan. Ceram. Assoc.* **47**, 141–5(1939). — These clays are produced at Gokoshi in Fukuken of Hotensho. They comprise a stratum of 4 common clays and a stratum of 5 hard clays. Refractoriness of the common clays is cone 34–35. They are very plastic: Al_2O_3, SiO_2 and P. C. E., resp., of the hard clays are: common hard clay, 45%, 35%, cone 35; superior hard clay, over 60%, under 20%, cone 37; special hard clay, over 70%, under 10%, cone 38. S. Kondo 1

The origin, mineralogy and distribution of the refractory clays of the United States. Arthur F. Greaves-Walker. *N. Carolina State Coll. Agr. Eng., Univ. N. Carolina, Eng. Expt. Sta. Bull.* No. **19**, 87 pp.(1939). E. H. 2

Determination of quartz (free silica) in refractory clays. L. J. Trostel and D. J. Wynne. *J. Am. Ceram. Soc.* **23**, 18–22(1940).—A rapid procedure is as follows: Weigh a 0.5-g. sample of dried material ground to pass 150-mesh, 3 in a vitreous SiO_2 crucible. Fuse with 10–15 g. $K_2S_2O_7$ starting at low temp. to prevent loss of SO_3. Dissolve the cooled fusion in 150–200 cc. of hot H_2O in a 400-cc. beaker. To the warm soln. add cautiously about 12 g. of NaOH pellets, one or 2 at a time, to dissolve the pptd. SiO_2. Digest on a hot plate for 1/2 hr. at 85–90°, then filter off the quartz quickly, using a paper of close texture. Wash 10 times with hot H_2O, then 5–10 times with hot 1:1 HCl to dissolve the Fe and other compds. from the quartz 4 not entirely removed by filtering; wash again 5 times with hot H_2O. Ignite and weigh in a tared Pt crucible. The residue is free quartz. To the residue add 2 drops of 1:1 H_2SO_4 and 10 cc. 48% HF; evap. to dryness, ignite and weigh. If this residue exceeds 0.001 g. discard the detn. and repeat. The procedure has proved useful on the more common unfired refractory clays; its value for high-temp. forms of cryst. SiO_2 and fired fireclay products remains to 5 be studied. C. H. Kerr

Manufacture of high-grade firebrick of highly aluminous clays (Preliminary report). Kozo Kawai and Syuzo Siowaki. *J. Japan. Ceram. Assoc.* **47**, 136–40(1939).—In Japan, most highly aluminous bricks are made from fire clays of Manchuria and North China. Their P. C. E. is cone 37 or 38. They are not satisfactory, since their softening temp. under a load of 2 kg. per sq. cm. never exceeds 1400°. To obtain fire brick contg. corundum and 6 mullite but no free SiO_2, Al_2O_3 or diaspore and mineralizers were added to highly aluminous Chinese clays and the brick fired to cone 18 or higher. Two of the resulting bricks had the following properties, resp.: true sp. gr. 3.09, 3.10; absorption 9.72, 8.33%; softening temp. under load of 2 kg. per sq. cm. 1535°, 1555°. S. Kondo

How to increase the corrosion resistance of bricks for chemical tanks. Adolf Moser. *Sprechsaal* **73**, 2–3 7 (1940).—Increased temp. and time for firing improved porosity, permeability, and corrosion resistance. Firing at cone 26 rather than at cone 14 improved all these properties. J. M. Noy

Low-fire glazes for roofing tiles. Yosio Mizuno. *J. Japan. Ceram. Assoc.* **47**, 294–7(1939).—A popular bluish green glaze for roofing tile in the Province of Mikawa is made of frit 55, feldspar 47, quartz 10 and cupric oxide 4.5; the frit batch being borax 38, feldspar 5, soda ash 8 12, limestone 14, kaolin 4 and quartz 27. Various glazes were prepd. of raw borax for a firing temp. of 1000–1050°. Satisfactory bluish green glazes were made contg. raw borax 50–40, soda ash 10, feldspar 20, quartz 15, limestone 5 and CuO 3–4 parts. S. Kondo

Titanium compounds. IV. Siniti Suzuki. *J. Japan. Ceram. Assoc.* **47**, 8–12(1939).—Phys. and elec. properties were detd. of 17 bodies contg. 0.007–0.047 KNaO, 0.088–0.095 CaO, 0.057–0.072 MgO, 1.00 Al_2O_3, 0.007–0.035 Fe_2O_3, 2.410–5.842 SiO_2 and 0.449–3.475 TiO_2. Results: The min. value of tan δ is shown with a body contg. 2.6 mol. TiO_2. For bodies rich in alkalies, it occurs at 0.5–0.6 mol. TiO_2; hence the effect of the TiO_2 is reduced by the change of the oxide into a basic substance. Tan δ and dielec. const. decrease with a rise in firing temp. until overfiring occurs. A body contg. 0.007 KNaO, 0.088 CaO, 0.069 MgO, 1.000 Al_2O_3, 0.007 Fe_2O_3, 2.731 SiO_2 and 2.612 mol. TiO_2 had a tan δ of 9.1 × 10^{-4}, when fired to cone 10. V–VI. *Ibid.* 123–30(1939).—To obtain satisfactory insulator for high-frequency current, firing and elec. examns. were made of 150 bodies in systems (*A*) kaolin–feldspar–quartz–TiO_2, (*B*) kaolin–feldspar–quartz–$CaCO_3$–Al_2O_3–TiO_2, (*C*) talc-feldspar–kaolin–TiO_2 and (*D*) kaolin–feldspar–quartz–$CaCO_3$–TiO_2. Thermochem. considerations are given for the reduction of TiO_2 to Ti_2O_3. Five bodies were obtained in system (*D*) that were superior to steatitic. The mol. compns. of these 5 were:

No	Na_2O	K_2O	CaO	MgO	Al_2O_3	SiO_2	TiO_2
IP 1	0.030	0.027	0.479	0.071	1.000	3.020	0.243
IP 2	0.029	0.026	0.669	0.069	1.000	2.700	0.243
IP 3	0.029	0.029	0.864	0.070	1.000	2.373	0.281
IP11	0.058	0.042	0.525	0.069	1.000	3.060	0.272
IP12	0.056	0.041	0.723	0.071	1.000	3.260	0.270

The absorptions (cone 14 burning) of the 5 bodies were 0.49, 0.22, 0.00, 0.00 and 0.00%, resp. The dielec. consts. were 5.11, 5.28, 4.40, 7.46 and 7.11, resp. The dielec. losses (× 10^{-4}) were 6.0, 7.9, 9.8, 13.9 and 10.6, resp. **VII.** *Ibid.* 243–8.—To aid in obtaining insulators of high dielec. const. the bodies now used were classified into vitrified rutile and titanate bodies. Forty-eight new bodies contg. $(NH_4)_2HPO_4$ as a mineralizer were prepd. and fired to cones 10 and 12, and tested for dielec. const. and tan δ. The effects of admixts. and firing temp. also were studied. S. Kondo 4

The diatomaceous earths of the Noto Peninsula. I. Their occurrence and quality. Masami Ono and Seizi Kondo. *J. Japan Ceram. Assoc.* **47**, 3–7(1939).—Diatomaceous earth produced near Wakura hot spring is typical. Its analysis is: loss on ignition 10.22, SiO_2 74.28, Al_2O_3 11.79, Fe_2O_3 1.59, CaO 0.56, MgO 0.82%. S. K.

Agalmatolite of Gahoku Hill in Korea. Takahiko Ukisu. *J. Japan. Ceram. Assoc.* **47**, 201(1939).—Descriptions are given on the production and quality of agalmatolite (Roseki) of Gahoku hill near Mituyo town in Keisho-nando, Korea. The hill is a solid mass of agalmatolite. Its refractoriness varies from cone 36 to 32. It is particularly useful in improving the load-bearing behavior of medium and superior fire brick. S. Kondo

Magnesia spinel. Siniti Suzuki. *J. Japan. Ceram. Assoc.* **47**, 302–9(1939).—A study was made of the refractoriness, load-bearing behavior, soly. in *N* soln. of mineral acids, linear expansion, and microstructure of magnesio-aluminous bodies made of Manchurian magnesites, Al_2O_3, and inland diaspores. The spinel bodies were sufficiently matured at cone 18. Formation of spinel was favored by the introduction of B_2O_3 and SiO_2. S. K.

Viscosity of transparent fused silica. Hideo Inuzuka. *J. Japan. Ceram. Assoc.* **47**, 292–4(1939).—The viscosity of transparent fused SiO_2 was detd. by English's method. The elongation Δl caused by a wt. suspended from the end of the specimen was measured by a cathetometer. The viscosity was calcd. from the formula $\eta = P.l.T/a^2\Delta l$ where P = wt. in dynes, l = length of specimen, T = time, a^2 = sectional area of specimen, and Δl = elongation. The softening temp. of the specimen was about 1150°. When a specimen was used for each temp., the relation between log η and temp. was rectilinear for temps. 1130–1430°. However when a specimen was used for several temps., the line was a little curved for 1100–1200°, probably from devitrification. S. Kondo 8

Inversion of dicalcium silicate. Seizi Kondo, Tosiyosi Yamauti and Mititane Oki. *J. Japan. Ceram. Assoc.* **47**, 76–81(1939).—Specimens were prepd. by heating mixts. of pure $2CaCO_3 + SiO_2$ for 2–8 hrs. at 1400–1700°. They were quenched in ice-cold Hg and examd. for microstructure, x-ray diffraction, thermal changes, etc. Specimens made at 1500° or over dusted less than those prepd. at lower temps. All specimens quenched in an ice-cold Pt crucible or in a similar way were mixts. of α- and β-$2CaO.SiO_2$. When the temp. was raised gradually to above 1500°, the products quenched as above were poorer in the γ modification and richer in the α one, almost pure α-$2CaO.SiO_2$ being obtained at about 1700°. On cooling naturally, the products always 9

contained the α form. Pure γ-$2CaO.SiO_2$ can be obtained from its mixt. with the α form by sieving, collecting the fine powder, reheating for a long time at temps. at which the α form is stable (e. g., 300 hrs. at 550°), and also by dissolving the α form in water. In thermal analysis, γ-$2CaO.SiO_2$ showed a strong endothermic reaction at 720 ± 5° in heating up and a strong exothermic one at 690 ± 5° in cooling. These changes are probably due to γ-β inversion. Slight exothermal changes were noted in α-$2CaO.SiO_2$ and in $3CaO.2SiO_2$ at temps. of 600 700°; they are due probably to γ-β inversion of γ-$2CaO.SiO_2$ contamination in the specimens. S. Kondo

Mineralizers effective in the crystallization of mullite. Tosio Nakai and Yosio Hukami. *J. Japan. Ceram. Assoc.* **47**, 225 7(1939).– An x-ray study was made of the effect, on the formation of mullite, of the addn. of 0.5, 2 and 5% of mineralizers to (*A*) a Korean kaolin, (*B*) a mixt. of the kaolin and Al_2O_3, and (*C*) a mixt. of quartz and Al_2O_3. Eleven compds. (CaO, Li_2O, Na tungstate, CdO, MgO, Bi subnitrate, PbO, NH_4 molybdate, B_2O_3, MnO_2 and CuO) were effective. In every case, the temp. at which mullite crystals were formed was lowered 50 200°. Each mineralizer has it's own most effective temp. The compds. of Mo and B are most effective at relatively low temps. CuO is effective at both lower and higher temps. MnO_2 is most effective at higher temps., although moderately effective at lower temps. Na_2WO_4 is moderately effective through a wide range of temp. CaO, Li_2O and MgO are similar to MnO_2 in regard to temp. though less effective. CdO, Bi subnitrate and PbO are least effective for all temps. The temps. in the expts were 950 1100° in (*A*), 1250 1400° in (*B*) and 1300-1450° in (*C*). S. Kondo

Properties of ceramic diaphragms. M. Sanada. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 314(1939). By use of the methods of Stender (*C. A.* **29**, 2856[7]) and of Encken and Jakob (*C. A.* **29**, 6327[2]), the chem. compn., acid- and alkali-resistance, true and apparent sp. gr., total porosity, pore size, elec. resistance, permeability and diffusion of ceramic diaphragms were investigated.
George Ayers

Manufacture of Seger cones. I. Tosio Nakai and Yosio Hukami. *J. Japan. Ceram. Assoc.* **47**, 233 7 (1939). –Expts. on feldspars are reported. Diffraction patterns of orthoclase, anorthoclase, albite, oligoclase, andesine, labradorite and anorthite are given and discussed. True sp. gr. of 7 specimens in the cryst. and the glassy states are 2.575 2.785 and 2.371 2.703, resp. The change in true sp. gr. on heating the specimens at 1050 1300° is given. Results indicate the existence of a eutectic between orthoclase and albite. The effects of MgO, CaO, borax, PbO, quartz and kaolin on the m. p. of orthoclase and albite are shown graphically. S. Kondo

Internal structure of Japanese potteries. Tosio Nakai and Yosio Hukami. *J. Japan. Ceram. Assoc.* **47**, 347 51 (1939).– Tableware of 7 chief porcelain-producing districts, those of 2 porcelain plants, a tableware of a china plant, and an elec. insulator product were examd. for chem. compn., x-ray diffraction and sp. gr. Results: Chem. compn., SiO_2 68 80, Al_2O_3 16 26 and alkalies 3.5 6%; crystals present, quartz, mullite and cristobalite; sp. gr. 2.41 2.56. S. Kondo

Magnesian porcelain steatitic. VIII. Syoitiro Nagai and Akira Naruse. *J. Japan. Ceram. Assoc.* **47**, 238 43(1939); cf. *C. A.* **30**, 2338[8]. –It was found from a preceding study that an addn. of 5 10% ZnO (Jap pat. 120,960, July 1, 1937), 3 15% Al_2O_3, or some pulverized Zn, Al or Mg (Jap. pat. 124,041, March 7, 1938) to talc improves the products. The present article relates mainly to the effects of various oxides. Talcs of Korea, Manchukuo and Shantung peninsula of North China are very pure. An addn. of 5% Al_2O_3, 10 15% ZnO, 5% BaO or 5% PbO to pulverized Manchurian talc was beneficial, while TiO_2 and Cr_2O_3 were not. S. Kondo

A study of heat-insulating materials. I. Tosio Nakai and Yosio Hukami. *J. Japan. Ceram. Assoc.* **47**, 283 7 (1939).—The plate method of detg. thermal cond. proposed by Nukiyama was introduced (cf. *C. A.* **30**, 7021[1]). 1 The detns. were made on a glass wool, a diatomaceous earth, and a diatomaceous-earth brick. The relations between cond. and bulk d. are discussed. Detns. of x-ray diffraction and true sp. gr. of insulating brick proved that a change in lattice structure greatly affects the thermal cond. of the brick. S. Kondo

Deformation of insulating firebrick under load. C. L. Norton, Jr., and V. J. Duplin, Jr. *J. Am. Ceram. Soc.* **23**, 22 5(1940).—In an electrically heated furnace load 2 was applied to full-size insulating firebrick. Sixteen com. brands were tested under various loads and over a considerable range of temp. No apparent relation was found between cold strength and deformation under load. A dense, strong brick did not necessarily carry more load at high temp. than a light, fragile brick. Some of the brands with best load-carrying capacity were also among the lightest tested. Bulk d. and cold strength, in general, did 3 not indicate ability to withstand hot-load conditions. Some brands of light-weight insulating firebrick actually carried more wt. at the same temp. than 2 samples of dense firebrick tested. It is surprising that a refractory which consists of 80% solid matter may not stand as much load at high temp. as another contg. only 20% solid matter.
C. H. Kerr

Fire resistance of ceramic building materials. H. D. Foster. *Ohio State Univ., Eng. Expt. Sta. News* **11**, No 4 5, 11 13(1939). J. M. Noy

Coal-fired kilns of Matumura. Zirokiti Kumazawa. *J. Japan. Ceram. Assoc.* **47**, 34(1939). S. Kondo

The third symposium of the Special Committee for Refractories. Anon. *J. Japan. Ceram. Assoc.* **47**, 35 41, 95 105(1939).– Third symposium of the special committee of the Japan Ceram. Assoc. and the Japan Refractories Assoc. The method of detg. P. C. E. and indicating the result, the reliability of cones, the methods of 5 testing for spalling tendency, expansion or contraction, load-bearing behavior at high temp., porosity, absorption, sp. gr., chem. analysis, sampling, corrosion, abrasion, specifications for silica, clay, agalmatolite, high Al_2O_3 and rotary kiln refractories were discussed. S. Kondo

Practical problems on the refractories for metal-melting furnaces. Tokizi Isikawa. *J. Japan. Ceram. Assoc.* **47**, No. 558, Suppl. 11 14(1939). Silica brick for open-6 hearth furnaces must have refractoriness of cone 33 or over, allowable deviation in dimensions being ±2% in length and width and ±2.5% in thickness. S. Kondo

Raw materials of refractories. I. Takeo Ao. *J. Japan. Ceram. Assoc.* **47**, 351 5(1939). The mineralogical and chem. compn., refractoriness, and sp. gr. of Roseki clay or agalmatolite are discussed. Three grades are recognized: the higher grade or diaspore-agalmatolite consists of diaspore and a small proportion of kaolinite, 7 the medium grade or kaolinite-agalmatolite is a mixt. of kaolinite and pyrophyllite; the lower grade or pyrophyllite-agalmatolite is composed of pyrophyllite and accessory minerals as quartz, sericite, alunite. S. Kondo

A proposal for the revision of the specification for the refractories of rotary cement kilns. Committee on Special Refractories. *J. Japan. Ceram. Assoc.* **47**, No. 558, Suppl. 3 10(1939).—The refractories are classified into 8 *A*, *B*, *C*, *D*, *E* and *F*. Allowable deviations in size, ±1.5% in length and width, and ±2.5% in thickness. Min. content of Al_2O_3: *A* 45, *B* 40, *C* 35, *D* 30 and *E* and *F* 25%. Min. P. C. E.: *A* 34, *B* and *C* 32, *D* and *E* 30, and *F* 26. Absorption: *A* to *E* 12 and *F* 11%. Max linear shrinkage on reheating for 4 hrs. at 1410°: −0.7% for *A* and *B*. Same for 4 hrs. at 1200°: ±0.2% for *C* to *F*. S. Kondo

Chemical analysis of refractories and their raw materials. 9 Syoitiro Nagai and Keiiti Akiyama. *J. Japan. Ceram. Assoc.* **47**, No. 556, Suppl. 1–4(1939).—The method recommended by a committee is given. S. K.

A proposal for the revision of the standard method of determining refractoriness. Committee for Refractoriness of the Japanese Ceramic Association. *J. Japan. Ceram. Assoc.* **47**, No. 558, Suppl. 1–2(1939).—The following revisions are proposed. The specimen is ground to pass a wire gauze sieve with 0.30 mm. openings. The

ground material is formed into truncated equilateral cones whose upper side, lower side and height are 3, 7 and 30 mm., resp. Standard and test cones are set in a refractory plaque, a face making an angle of 80° with the plaque and 4 mm. of its lower end being in the plaque. Intermediate cone equiv. is shown thus: cone 34–35. S. Kondo 1

A study on the manufacture of forsterite refractories. I. Tosio Ikeda and Tutau Hurukawa. *J. Japan. Ceram. Assoc.* **47**, 287–92 (1939).—A light-burned magnesite from Daisekkyo and a calcined talc from Kaijo were mixed in the proportions $MgO.SiO_2$, $2MgO.SiO_2$, $3MgO.SiO_2$, $4MgO.SiO_2$, $5MgO.SiO_2$, MgO and $3MgO.4SiO_2$. Small plates were formed under a pressure of 500 kg. per sq. cm.; they were fired at 1250°, 1350° and 1450° for 2 hrs. Then they were examd. for shrinkage, absorption, bulk d., sp. gr., and compressive strength. The $2MgO.SiO_2$ mixt. produced forsterite easily at lower temp. X-ray observation showed that fired talc consisted of clino-enstatite and SiO_2; $2MgO.SiO_2$ fired at 1250° contained clino-enstatite, but when fired at 1450° was composed almost entirely of forsterite. S. Kondo 2

The modulus of elasticity of magnesite refractories. XIII A method of improving mechanical strength of unfired magnesite refractories at ordinary and high temperatures. Seizi Kondo and Hiroşi Yosida. *J. Japan. Ceram. Assoc.* **47**, 15–17 (1939).—Mixts. of 80 or 100 parts of a pulverized clinker and 20 or 0 parts of a pulverized caustic burned magnesite were mixed with aq. soln. of dextrin, $MgCl_2$ and $MgSO_4$ and formed into test pieces under a pressure of 1000 kg. per sq. cm. Compressive strength was detd. after 1 week, that on drying, that on heating at 100 1160°, and that on firing to cone 16. The temp. producing the least compressive strength of each mixt. was lowest with dextrin, medium with $MgCl_2$ and highest with $MgSO_4$. The range of temp. at which the $MgSO_4$ specimens showed the lowest or like strengths was narrow. Test pieces which were made of the pulverized clinker and a soln. of $MgSO_4$ showed a min. hot compressive strength of 294 kg. per sq. cm. They can probably be used without firing. Their linear firing shrinkage was about 5%. However, the shrinkage can be reduced 50% by introducing coarse grains of clinker up to about 50%. **XIV. Chemical composition versus spalling character.** *Ibid.* 131 5 (1939).—Adding 5 parts of Al_2O_3 to 95 parts of pulverized magnesite clinker was remarkably effective in reducing spalling. The aluminous test pieces were fired to cones 12–28; they were vitrified at cone 16 and over. The spalling tendency of test pieces made with varying amts. of coarse clinker grain and fine aluminous powder was detd. Also the spalling tendency and the lowering of the modulus of elasticity of 5 other Manchurian magnesites were examd. Finally specimens made of a pulverized clinker with addns. of SiO_2, Al_2O_3, Fe_2O_3 and CaO were tested for spalling. Conclusions: The addn. of SiO_2 or CaO is detrimental, if some remains in the free state. The addn. of Fe_2O_3, MnO_2, TiO_2, $SrSO_4$, BaF_2 or $BaSO_4$ increases the spalling tendency. When Al_2O_3 or Cr_2O_3 exceeds a certain amt. the elasticity is abruptly increased and the spalling tendency suddenly lowered. The spalling tendency of specimens contg. effective amts. of Al_2O_3 or Cr_2O_3 decreases with a rise in firing temp. The effect of Cr_2O_3 is greater than that of Al_2O_3 at higher firing temps. The effective amt. of Al_2O_3 is not affected by introducing 10% Fe_2O_3 or SiO_2, while it varies if small amts. of CaO are added. When coarse grains of clinker are bonded with its own fine powder plus Al_2O_3, specimens contg. about 35% or less of the fine powder are inferior to those made with fine powder only. Specimens with 5% Al_2O_3 and also 1.5% CaO added vitrify better, are more resistant to thermal shock and are better in load-bearing capacity than specimens with 5% CaO and 10% Fe_2O_3 added. S. Kondo 3 4 5 6 7

Considerations on the modulus of elasticity and spalling. I. Siniti Suzuki. *J. Japan. Ceram. Assoc.* **47**, 230–3 (1939).—Difficulties in the detn. of the modulus of elasticity are discussed. Plastic deformation is closely related to the modulus. S. Kondo

Stannic oxide in ceramic glazes. Ludwig Stuckert. *Sprechsaal* **73**, 13–15, 21–3, 29–31, 37–9, 45–6 (1940).—The soly. of SnO_2 in the frits normally in use was investigated. Slow cooling reduces soly. due to supersatd. soln. With PbO the soln. reverses almost completely during the cooling, while frits rich in alkali metal oxides dissolve the SnO_2 irreversibly. It is advisable not to introduce the SnO_2 entirely with the frit (in the latter case) but to add it also to the mill. In general, SnO_2 increases the ease of melting, and the resistance to acids. The results with B_2O_3 are similar to those with PbO, in combination with SnO_2. Al_2O_3 is more favorable than SiO_2 and should not be eliminated entirely. ZrO_2 can replace SiO_2 in combination with SnO_2 or even replace SnO_2. To replace PbO with alkali metal oxides is always detrimental. In cases where 3 components are used certain ranges are defined as applicable. Other means of rendering glazes opaque are not advisable, except fluorspar, which combines with SnO_2 increasing its effect. J. M. Noy 8

Protecting metals by vitreous enamels. A. E. R. Westman. *Can. Metals Met. Inds.* **3**, 38 41 (1940).—A general review of vitreous enamels and their use for the protection of metals. Points considered are: the nature and compn., the enameling process, some of the more interesting developments in the last decade and the use of vitreous enamels for protecting metals against atm. corrosion. The vitreous-enameled products used most extensively to combat atm. corrosion are enameled sign and architectural units. W. H. Boynton 9

Enameling zinc-alloy die-castings; the necessity of chemical pretreatment. E. E. Halls. *Ind. Chemist* **15**, 433–6, 443 (1939).—The compn. and mech. properties of the principal Mazak Zn alloys (similar to Zamak series in U. S.) are tabulated. Chem. pretreatments are indispensable for sound, durable finishes. The Zn surface must be converted into an inert compd. which exerts no chem. action on the org. film coating. The 2 most widely used treatments are phosphatizing (Parker PZ and Granodine processes) and the chromate process. Test results show practically all types of industrial finishes as satisfactory with phosphate or chromate pretreatment. Special types of Al powder media also reduce the rate of failure somewhat. Failure is attributed primarily to interaction between Zn and moisture passing through the covering film of paint or enamel. M. McMahon 10

Effect of enamel on the strength of enameling iron. A. I. Andrews and E. W. Dietterle. *J. Am. Ceram. Soc.* **23**, 29 32 (1940).—Ground-coat enamel was applied on one side and on both sides of 26, 20, 18, 10 and 6-gage enameling stock and the strengths were detd. in cross bending. The enameled specimens showed a decided increase in strength over that of the stock before enameling. Increase in enamel thickness increased the strength within limits. The effect on the lighter gages was greater than on heavy gages. The strength was greater when the enamel was under compression than when under tension. C. H. Kerr 11

Apply thin, uniform ground coats by electric deposition (Badger, King, Jr.) **4**. Acidproof masonry in the sulfite industry (Björnstad) **23**. Transparent, rubbery sheets of polyvinyl acetal resin [for laminated-glass manuf.] (U. S. pat. 2,184,442) **13**.

Method and apparatus for casting vitreous articles. The British Thomson-Houston Co. Ltd. Brit. 508,295, June 28, 1939. In casting fused vitreous material, e. g., glass, in contact with a surface to which the fluid material normally adheres, adhesion is prevented by interposition of a layer of B nitride. Molds for use in casting glass may have their receiving surface coated with a layer of the B nitride.

Copper linings for mirrors, etc. Paolo Misciattelli. U. S. 2,183,202, Dec. 12. See Brit. 490,159 (*C. A.* **33**, 1118[2]).

Seals between ceramic and metal parts of potheads and like electrical fittings. Standard Telephones and Cables

Ltd., Thomas R. Scott and Leonard A. C. Pooley. Brit. 508,693, July 4, 1939. A filling of a cementing material consisting of styrene (I) or an insulating compn. contg. I is provided between the parts, the cementing material then being polymerized *in situ*. The cementing material may be plasticized as in Brit. 490,814 (*C. A.* **33**, 1062[7]) and may be blended with rubber, etc., with or without the addn. of rubber plasticizers, e. g., ceresin wax; it may be I admixed with an olefin, e. g., polyethylene, polyisobutylene.

Forming sealed joints between an outer metal body and an inner ceramic body. Otto Bormann (sole responsible partner of Julius Pintsch Kommanditgesellschaft). Brit. 508,542, June 29, 1939.

Electrically heated double tunnel furnaces. Aktiengesellschaft Brown, Boveri & Cie. Brit. 508,738, July 5, 1939. In furnaces for firing ceramic articles, these are conveyed through the furnace in counterflow, 1 tunnel serving for biscuit firing and the other for glaze firing, a longitudinal wall completely sepg. the tunnels over the whole length of the furnace so that the 2 processes can be accomplished simultaneously at different const. temps.

Apparatus for deaerating clay slips for making ceramic ware. Davis Brown. U. S. 2,183,763, Dec. 19. Various structural, mech. and operative details.

Pottery. Wm. Salisbury. U. S. 2,183,944, Dec. 19. App. is described, and a process for producing pottery, comprising pugging clay to a degree of stiffness beyond that suitable normally for jiggering thereof, simultaneously forming a portion of the pugged clay into a pair of gobs of approx. equal mass, shaping the gobs in sep. molds into complemental elements of a container with rim portions on the elements, drying the elements equally to a stage where they are mutually nonadhesive, coating the rim portion with a slip, abutting the coated rim portions for effecting assembly into a container, and firing the assembly to unite the complemental elements to form a container, such as a teapot.

Abrasive compositions. The Carborundum Co. Brit. 508,486, June 30, 1939. An abrasive or hard-wearing compn. is formed from a fusion contg. B carbide (I) and 1 or more addnl. hard carbides, e. g., of Zr, W, Mo, Cr, Ti or Si, having the hardness of Mo carbide or greater hardness and present as a sep. cryst. phase that has solidified from the fused mass. The I is preferably the major constituent. The addnl. carbide may occur, at least in part, as a eutectic in the form of finely divided particles distributed through a matrix in which the I forms a basic ingredient, or partly as eutectic and partly as cryst. plates or, with further increasing proportions thereof, as a cryst. skeleton extending through a hard tough matrix of I, the skeleton dividing the matrix into vols. that are bounded by substantially plane surfaces and (or) sharp corners or edges.

Abrasive sheets. Donald E. Edgar and Harry G. Stauffer (to E. I. du Pont de Nemours & Co.). U. S. 2,184,293, Dec. 26. Abrasive material is bound to sheet material such as paper or cloth by a resinous reaction product such as may be formed of urea, CH_2O and an alc. such as iso-Bu alc. in specified proportions, which on treatment with $ZnCl_2$ and Ac_2O yields the acetate of the alc. Cf. *C. A.* **33**, 7513[2]; **34**, 2150[2].

Magnetic apparatus suitable for coating paper or cloth with abrasive material. Henry P. Kirchner and Raymond C. Benner (to Carborundum Co.). U. S. 2,184,348, Dec. 26. Various structural and operative details.

Emery boards. Marshall T. Brekke (to Northam Warren Corp.). U. S. 2,183,930, Dec. 19. Various mfg. details.

Apparatus for separation of air from slip. Japan. 128,727, March, 1939. Atuzi Terasaki. Slip is introduced at the top of a vacuum chamber, and flows in a thin layer over inclined zigzag plates.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

The fineness of cement. Kimbe Tyuzyo. *J. Japan. Ceram. Assoc.* **47**, 248–53, 297–302, 361–5(1939).—The application of air analysis to the study of the fineness of cement was investigated. Two groups of limit particles for 2 velocities were collected with a Gonell's analyzer. Then 400 particles of the groups were examd. by means of ocular micrometers for plane area f, height t and other dimensions. The frequency curves of these dimensions indicated that diam. of each particle is best represented by $\sqrt{ft}$. The Goldstein or the Oseen formula holds for the relation between vol. and velocity of flow in the cross section of the tube. The air analyzers of the Petersen type, English and American standard types, Gary and Lindner type, Gonell type, and Reller type are discussed, and results are given of tests of T.'s analyzer (Jap. pat. No. 114,750, March, 1936). The error due to the time of analysis is discussed. To find a rational method of calcg. the sp. surface of cement, T. examd. the outer shape of grain and the grain distribution. The statistical shapes of the grain are similar regardless of its size and brand of the cement. S. Kondo

Researches on the mechanism of cement formation in rotary kiln. III. X-ray analysis of cement raw meal in the rotary kiln. T. Yosii. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 304–5(1939); cf. *C. A.* **33**, 7069[1,2].—X-ray studies were made on cement samples from the drying (wet process), preheating, calcining, sintering and cooling zones of a cement kiln. The diffraction line of limestone was present in samples for 70% of the length of the kiln. Following this region the lines of free lime appeared, and finally those of alite and belite and possibly some of celite. Limestone, free lime and a small amt. of belite were detected in the flue dust. **IV. General description of the microscopical examination of the raw meal in the rotary cement kiln.** *Ibid.* 305–8.—Pulverized limestone gave a n below 1.68, birefringence of about 0.17, clay aggregates gave a n 1.540–1.552 and a strong birefringence (cericite or pyrophyllite series). Purple ore, a by-product from H_2SO_4 contained small amts. of limestone, quartz and clay. The clinker contained alite ($3CaO.SiO_2$), belite (α-$2CaO.SiO_2$) and celite ($4CaO.Al_2O_3.Fe_2O_3$). **V. Microscopical examination of raw meal in the rotary kiln.** *Ibid.* 308–13.—In both wet and dry processes samples from the first 70% of the length of the kiln gave predominantly $CaCO_3$ diffraction patterns. In the dry process at about the 70% point $CaCO_3$ dissocn. begins and continues over approx. 15% of the kiln length. At the 85% point the first belite and celite formation occurs. At the 90% point the transformation of belite to alite is quite rapid and clinker is forming. Finished clinker consists of alite, belite and celite. In the wet process $CaCO_3$ dissocn. takes place from 70–85% kiln distance from the feed end. At 80–85% distance belite and celite are formed first, at about 93% distance transformation of belite to alite is rapid, and celite crystals are becoming well developed. The finished clinker consists of alite, belite and celite with no free lime. H. E. Messmore

Fluxes in cement mixes. S. E. Hutton. *Rock Products* **42**, No. 11, 51–2(1939).—A general, inconclusive discussion of the effectiveness of Fe_2O_3 and Al_2O_3 as fluxing agents in the manuf. of portland cement clinker based on analyses as reported in the periodical literature by Blank (*C. A.* **22**, 4219), and others. A. W. King

Shrinkage [of cement]. Vieri Sevieri. *Tonind.-Ztg.* **63**, 288–90(1939).—So many factors in mixing concrete influence shrinkage that the results of expts. on its avoidance by adjustment of the chem. constitution of cement may be entirely obscured. Most improvement in shrinkage, as in strength, comes from improvement of the phys. character of the cement and mode of prepg. the concrete,

rather than from changes in compn. of the cement. B. C. P. A.

Properties of cements and limes subjected to high pressures. F. Jager. *Cement Lime Manuf.* **12**, 1–3(1939).—Pressures up to 18,000 kg./sq. cm. exerted on dry powders showed that subsequent reaction with water at first was accelerated then retarded and finally close to zero, depending on the pressure. Above a certain pressure the cement powders coalesced to give extremely low reactivity. A. W. King

Blended cements. Kozaburo Watanabe. *J. Japan. Ceram. Assoc.* **47**, 355–7, 358–60(1939).—The blending materials were calcined clay, raw clay, siliceous white clay, diatomaceous earth, sol. white clay ("Kayoha-kudo") and volcanic ash. The best blended cement was obtained with sol. white clay, contg. SiO_2 85.00, Al_2O_3 6.40, Fe_2O_3 1.10, CaO 2.50, SO_3 1.03, and insol. residue 22.04%; loss on ignition was 5.6%; the sol. constituents cond. 69.04 SiO_2 and 5.40 Al_2O_3 and Fe_2O_3. The higher the sol. silica the better was the material. Materials rich in sol. alumina improved early strengths, especially compressive strength. Bending strength was favored by the materials rich in sol. silica. The strengths of wet mortars composed of 1 part cement, 1 part fine sand and 2 parts standard sand after immersion in water, $MgSO_4$ soln., Na_2SO_4 soln. and $(NH_4)_2SO_4$ soln. were compared. The higher the sol. silica in the blending materials, the better was the chem. resistance. Materials rich in sol. alumina gave blended cements that had poor resistance to Na_2SO_4 soln. S. Kondo

Investigations on the properties of portland cement made with sand. V. A. Kind, V. F. Zhuravlev and Kh. P. Kotlyar. *Tsement* **5**, No. 12, 6–9(1937); *Chimie & industrie* **40**, 506.—Portland cement made with sand is slightly less resistant to air than ordinary portland cement, but its air-hardening is not interrupted but merely proceeds at a slower rate. Deformations by contraction and swelling of sand portland cement kept under water are slightly smaller than the corresponding properties of ordinary portland cement; contraction in air is slightly greater, but still remains within permissible limits. Generally speaking, from the double standpoint of mech. strength and the principal technological qualities, sand portland cement is practically equal to standard portland cement. The incorporation of fine sand accelerates hydration of the cement, which explains the good mech. properties of sand portland cement. A. P.-C.

Colored portland cements. II. M. Ya. Bychkov and K. S. Zatsepin. *Tsement* **5**, No. 12, 10–12(1937); *Chimie & industrie* **40**, 506; cf. *C. A.* **32**, 1423[1], 1891[7].—Study of the use of different Mn compds. in the prepn. of colored cements. The color obtained depends on both the nature and the proportion of the compd. used, e. g., 1% pyrolusite gives a brownish gray cement, and 5% pyrolusite gives a black cement with a slight brownish tinge; 1% Mn chloride gives a light-gray cement and 5% a yellowish gray. The mech. strengths of the cements are also different. A. Papineau-Couture

Mixed portland cement. Seizi Kondo and Aitaro Miyagawa. *J. Japan. Ceram. Assoc.* **47**, 191–6(1939).—Kaolin, quartz sand, pyrophyllite, potter's rock, bentonites of Aomori, liparite, and decomposed granite as 30% admixts. to portland cement were compared with the white earth of Beppu, which is widely used in the commercial production of mixed cement. The results of the expt. indicate that the bentonites are as good as the white earth. S. Kondo

Constitution of portland cement clinker. R. H. Bogue. *Proc. Symposium on the Chemistry of Cements, Stockholm,* 1938; *Cement Lime Manuf.* **12**, 205–13, 230–40, 250–6(1939); **13**, 3–11(1940).—A comprehensive presentation on the pos. identification of the various phases present in com. portland cement clinker by means of the most refined microscopic technique. Com. clinkers vary widely in glass content, which is profoundly affected by the rate at which clinker is cooled. Clinkers prepd. in a lab. furnace contg. 3% MgO, when cooled slowly (no glass), gave cements that expanded seriously when tested in the autoclave, whereas the same compns. when cooled quickly (high glass) had a very low expansion. A. W. King

Determination of the constitution of portland cement clinker by the metallographic method. Taro Tanaka and Ryuiti Naito. *Cement Lime Manuf.* **12**, 64–8(1939).—The metallographic method using polished and etched specimens, when combined with the petrographic method, aids considerably in studying the compn. of clinker; 7 photomicrographs. A. W. King

Limit values of the lime-saturation coefficient of high-grade portland cements. V. S. Chernitskiĭ. *Tsement* **6**, No. 8, 38–40(1939).—Max., mean and min. satn. coeffs. are, resp., 102–3.96 *C*, 100–3.7 *C*, and 98–3.5 *C* (*C* = silicate modulus). E. E. Stefanowsky

Effect of temperature on high-alumina cement. F. M. Lea. *J. Soc. Chem. Ind.* **59**, 18–21(1940).—An investigation made of the falling off in strength of set high-Al_2O_3 cement at temps. above normal, supports the hypothesis that a transformation of the metastable, less basic, hydrated calcium aluminates into the tricalcium aluminate hexahydrate is a major factor in this loss of strength. Tests of pure calcium mono-aluminate mortars also show a similar slump in strength. A. W. King

Aluminate-silicate cement. O. A. Gershberg and E. E. Gaĭsinovich. *Stroitel. Prom.* **17**, No. 7, 69–73(1939).—Aluminate silicate cement deteriorates on storage. Small addns. of portland cement or lime considerably accelerate its setting and decrease its strength. The accelerating effect of $CaCl_2$ is less. In moist conditions the strength of the concrete is 25% less than that of air-hardened concrete. E. E. S.

Construction with sulfur cement. C. R. Payne and W. W. Duecker. *Chem. & Met. Eng.* **47**, 20–1(1940); cf. *C. A.* **34**, 1455[1].—Acidproof cements for use in chem. plants should be of as low porosity as possible to prevent absorption of corrosive material. Concrete tanks are lined with a plastic S cement and then lined with acid-proof brick jointed with S cement. Steel tanks for continuous pickling of steel are frequently constructed as follows: the tank is first lined with rubber and this is protected by a lining of acidproof brick jointed with S cement. Pickling tanks lined in this manner have been in successful operation in plants for several years. H. E. Messmore

Some experiments with blast-furnace slags. N. I. Elagin. *Stroitel. Prom.* **17**, No. 4–5, 79–80(1939).—Slag powder was more active than granulated slag; it produces a strong cement with 1/6 the quantity of lime necessary for granulated slag. A lever press for the testing of samples is described. E. E. Stefanowsky

Experimental chromite-alumina linings at the Brjansk cement works. N. I. Khvostenkov and A. A. Tararin. *Tsement* **6**, No. 7, 1–3(1939).—Rammed chromite linings have twice the stability of chromite-brick linings owing to a greater homogeneity of the material and the absence seams. Chromite linings based on alumina cement are more stable for the sintering zones of rotatory kilns than are clinker concrete and talc linings. E. E. S.

A cement with hydraulic admixtures for filling (petroleum-well) crevices. N. A. Lutsenko. *Azerbaĭdzhanskoe Neftyanoe Khoz.* **1938**, No. 12, 25–9; *Khim. Referat. Zhur.* **2**, No. 5, 92–3(1939); cf. *C. A.* **31**, 8164[8].—Addns. of 10–20% of pumice to cement gave best results. The addn. of pumice lowered the temp. of the hardening of the cement. W. R. Henn

Method of determining the effective water-cement ratio in cement mortars. M. Cattaneo. *Strade* **21**, No. 2, 23–7(1939).—The amt. of H_2O absorbed varies with the type of sand used in the mortar; this H_2O is not available for hydration of the cement. Different cements also require different H_2O addns. to develop the optimum properties. These two amts. should be detd. separately to obtain the best conditions, but in practice still further addns. of H_2O are necessary to improve workability. B. C. P. A.

The bleeding of portland cement paste mortar and concrete. T. C. Powers. *J. Am. Concrete Inst.* **10**, No. 6, Proc. **35**, 593–608(1939).—A method is given for measuring bleeding which is treated as if it were subsidence or

sedimentation. The study shows that the adsorption and the immobile water factors open a new field of study as to the influence of salts on the bleeding characteristics. Air bubbles stabilized during the mixing period by certain foaming agents are very effective in reducing the rate and amt. of bleeding. Certain types of sealing are explained in terms of bleeding and the utility of delayed finishing is proved. A. W. King

The binding properties of compounds of the calcium aluminate and calcium silicate types. II. Binding properties of calcium chromites. V. F. Zhuravlev. *Trudy LKKhTI* **1939**, No. 7, 211–16; *Khim. Referat. Zhur.* **2**, No. 5, 90(1939); cf. *C. A.* **33**, 6017[1].—Mixts. of CaO and Cr_2O_3 in the ratios 1:1, 2:1, 3:1 and 4:1 were fired at 1350° for 2 hrs. in an elec. furnace and then rapidly cooled. Homogeneous products were obtained only from mixts. 1:1 and 3:1; this indicates the existence of only 2 binary compds., $CaO.Cr_2O_3$ and $3CaO.Cr_2O_3$. The $CaO.Cr_2O_3$ samples showed no binding properties while definite binding properties were observed in the $3CaO.Cr_2O_3$ samples. W. R. Henn

Sealing the lagoon lining at Treasure Island with salt. Charles H. Lee. *Proc. Am. Soc. Civil Engrs.* **66**, 247–63 (1940).—The clay lining was sealed successfully by salt water treatment (sea water), thus deflocculating the clay. The initial seepage in a test pool was 1.00 in. per day. This was reduced to 0.1 in. per day by the salt water treatment. The fresh water, used subsequently in the lagoon, did not increase in salinity. This method of sealing would appear to have a wide field of usefulness in constructing impervious membranes for water-works structures. W. D. Hatfield

Tests of concrete curing materials. F. H. Jackson and W. F. Kellermann. *J. Am. Concrete Inst.* **10**, No. 6, Proc. **35**, 481–500(1939).—Extensive tests involving the use of burlap, $CaCl_2$, Na silicate, 6 waterproof papers, mats, an asphalt emulsion, a cut-back, a lacquer-like liquid and a rubber-latex emulsion showed that the important factor in developing an adequately cured concrete is the continuous presence of enough water within the concrete to effect optimum hydration and crystn. Intermittent sprinkling is far from being as effective as concrete continuously satd. with water. A. W. King

Factors affecting the resistance to freezing and thawing of vibrated concrete made of crushed dolomite. M. O. Withey. *J. Am. Concrete Inst.* **10**, No. 6, Proc. **35**, 553–60(1939).—Flexure tests of 100 concrete prisms 6 in. by 6 in. by 18 in. subjected up to 150 freezing-thawing cycles show that very little damage is suffered by concrete with 0.54 water-cement ratio (6.1 gal. of H_2O per sack of cement), 0.25 in. slump and 4.75 sacks of cement per cu yd. Leaner mixes and wetter mixes with higher cement content are less durable. The flexural test is far more sensitive than any other used in this study for measuring the resistance to freezing and thawing. A. W. King

What components of sea water damage concrete? F. W. Freise. *Concrete Constr. Eng.* **33**, No. 11, 535–40 (1938); *Bldg. Sci. Abstracts* **11**, No. 12, 408–9(1938). Concrete specimens (1 2:4 mixture) were matured for 90 days and submitted to the action of salt solns. prepd. in the concns. found along the south coast of the State of Rio. Filtered rain water or distd. water was used with the salts, such as Na, K and Mg chlorides and $MgSO_4$ and raw salt manufd. locally. The raw salt contd. 93.5% NaCl, 1.1 to 1.35% $MgCl_2$, 0.07 to 0.12% $MgSO_4$ and 0.01 to 0.012% $CaSO_4$. The concrete specimens were kept in the solns. for 2 years, one series at the uniform temp. of 22° in a cellar, another at the open-air temps. varying from 15.8° to 42.2° under a dust-free shed. Evapn. was counteracted by the periodic addn. of the same kind of water in accordance with the results of titrimetric analyses made of the contents of the vessels. Some of the specimens were kept at rest, others were rotated slowly around a horizontal axis. The final wt. of the specimens after immersion was obtained by washing in warm water and drying to the moisture contents verified before beginning the expt. The wash water was analyzed. The results obtained are tabulated. The aggressive effect of the "common" salts present in sea water is practically nil, whether the salts be single or mixed to the oceanic concn. The slightly greater deterioration of the specimens kept in rain-water solns. is noteworthy. A parallel series of expts. was carried out on identical specimens exposed to natural sea water; the sp. gr., and compn., showing the amts. of both common and rarer components, are given. The results obtained are tabulated, and compared with those above. The damaging agents are the rarer components and the damaging action after a certain time becomes smaller and finally ceases. The latter effect is not due to the formation of a protective cover on the exposed surface but to the disappearance of some ingredient previously present in the sea water. To det. the effect of the rarer components several grades of mother lyes from the crystn. of "raw salt" were prepd., wherein concrete specimens made and cured as before were exposed for 2 years. No appreciable damage was noticed. Thus no ingredient in the mother lye is responsible for any damage to concrete. A typical lye used lacks a certain no. of constituents present in the sea water, namely, $CaCO_3$, NH_4HCO_3, NH_4 phosphate, SiO_2, Fe oxide and org. matter. When the last is subjected to an increase of salinity it decays; the dead matter reduces Fe oxide and the H_2CO_3 present in excess dissolves the FeO as bicarbonate of iron. This is deposited at the bottom of the salt bed as hydrate of Fe_2O_3, owing to the action of atm. O. In the same sequence of transformations the existing SiO_2, the traces of phosphates, and the greater part of the $CaCO_3$ are deposited in the bottom. Every missing ion is thus accounted for, with the sole exception of the NH_4HCO_3 present in the original sea water to the extent of 0.013 g./l. which seems to have totally disappeared. An NH_4HCO_3 complex is intimately connected with animal life in the ocean which builds a protective shell, and clams, for example, produce liberal quantities of this compd. The production increases with the growth of the mollusc, and amounts to many times the weight of the latter. By yet unknown forms of combination the complex is tenaciously secured in the water, but easily freed from it when the water salinity surpasses the grade proper for animal life. Wave movements or breaking surf have no influence on the complex. The damaging effect of sea water on concrete can therefore be traced exclusively to the presence of NH_4HCO_3 complex and as a proof thereof an expt. was undertaken in a wooden tank stocked with clams which were to live on the sea water filling the tank. Although the org. matter in the clams did not increase appreciably owing to the scarceness of food, $(NH_4)_2CO_3$ was liberally produced to increase their shells. Specimens, not directly in contact with the clams, began to show signs of damage after 10 weeks' suspension in the water; a cover of slime developed on all surfaces, and after 40 to 42 weeks a layer 0.01 in. thick could be removed easily by agitating the surrounding water. The slime is a carbonate of lime, that is, a substituted carbonate in which the radical NH_2 is present; the amt. of Ca is from 8 to 8.8%. The slightest currents on the open water are sufficient to bring the substance into the reach of the molluscs, by which it is readily assimilable for shell-building purposes, while diffusion brings the NH_4HCO_3 complex into contact with lime-yielding material. The action on concrete is strictly proportional to the amt. of this substance in the water, where it plays a merely transitory part. Losses of wt. in slabs in sea water with varying amts. of $(NH_4)_2CO_3$ complex at 3, 6, 12 and 24 months are recorded. Expts. with any com. NH_4 carbonates are quite neg., because the specific constitution of the substance produced by the clams cannot be reproduced artificially. Chem. damage to concrete from sea water is connected with a component intimately assocd. with molluscs. Remedies against the damage must be based on the removal of living molluscs from the neighborhood of immersed concrete by frequent dredging along the water front to remove the mollusc colonies, by using stone blocks rich in Fe granites rich in magnetite, and (or) pyrites because the sea water dissolves enough Fe to keep the molluscs away or by introducing fresh water

at the temp. of the surroundings or heated to between 60° and 80°. C. L. B. 1

Durability of concrete pavement—experiences in New York State. E. C. Lawton. *J. Am. Concrete Inst.* **10**, No. 6, Proc. **35**, 561–78(1939).—Case histories beginning in 1925 together with 50 odd exptl. projects have led to standard construction employing 1 bag of natural cement to 6 bags of portland cement in all pavement mixes, a tricalcium aluminate limit of 9% and a tricalcium silicate limit of 55%. A. W. King 2

Blast-furnace slag, road tar and tar macadam. P. Herrmann. *Asphalt Teer Strassenbautech.* **39**, 619–21 (1939).—A description of prepn. and uses of slag and tar for road building. F. W. Jung

Properties of binders and their adhesivity to road-construction stone. H. Suida, O. Jekel and K. Haller. *Asphalt Teer Strassenbautech.* **39**, 253–8, 267–72, 283–6, 295–300(1939).—The relation of increased addns. of C_6H_6-insol. to mixing time; the penetration, softening temp., drop point of Mexican and Rumanian asphalt and petroleum pitch to filler addns.; action of pH of water on adhesivity of binder films to stone; and adhesivity in still and flowing water have been investigated. From the adhesivity tests it is concluded: Properties of a binder are influenced little by finely pulverized filler if a high degree of dispersion is attained. A dispersible filler as free C or "hard asphalt" when added to tar or bitumen in the absence of air and evapn. will reach stability in properties. Free C will elevate viscosity in nearly geometric relation to the amt. added. Effects also vary with origin and method of prepn. and can alter the viscosity-temp. relation favorably. Adhesivity of tar to stone in presence of H_2O is improved proportionally by added free C; that of binder films depends largely upon properties of binder and stone, and pH of the H_2O, the last becoming more important as desirable properties of the binder and stone diminish. The pH of the H_2O influences the limiting surface tension between binder and stone surfaces. Soln pressure of stone at const. pH has little or no effect on adhesivity of binder film; influence is seen when pH is altered through soln. processes. Asphalt and tar generally behave similarly toward the same stone but the same binder will adhere differently to different stones. Each binder-stone combination has its characteristic degree of adhesivity-pH dependence; this is shown in min. adhesivity at or near neutralty or in a decrease with rising pH. Binders unlike stone do not alter H_2O pH at or near neutrality. Within the practical range pH 5.8–8 this dependence may be pronounced; for tests pH 6–7 should be maintained. Natural conditions call for little water in the tests, usual pH range, and tests in slowly flowing water at const. pH. Repeated colorimetric tests during tests are recommended. F. W. Jung 3 4 5 6 7

Bituminous emulsions. E. Vellinger. *Bull. assoc. franç. techniciens pétrole* No. **46**, 149–65(1938).—Bituminous emulsions of the proper viscosity for *road-building* can be obtained by increasing the bitumen content of the emulsion, by adding stearic acid pitch to the emulsion in addn. to the emulsifying agent, or better by adding sulfonic acid extd. from refinery acid residues. Stearic acid partially inverts the emulsion, i. e., disperses part of the water in the bitumen, but produces a highly thixotropic emulsion with a very high temp. coeff. Emulsions contg. sulfonic acids are not thixotropic and possess a satisfactory temp. coeff. The formula of Einstein is useless in explaining the viscosity of emulsions. It is necessary to consider the interface. To explain adherence V. admits the theory of the interfacial binder, i. e., for one substance to adhere to another, the presence of another intermediate substance having an affinity for both is necessary. This binder may be an adhesiphore, i. e., a unimol. layer of a substance having an affinity for both the bitumen and the coarse gravel to which it is to be bound. The adhesiphore thus acts as a wetting agent. Justification of this theory is explained. It is impossible to predict the constitution which an adhesiphore must possess. The following are also explained: the effect of the size of the bitumen particle on the emulsion, the stability of the bituminous emulsion as a function of the pH of the aq. phase, breaking of the emulsion, viscosity, and storage stability of the emulsion. E. J. Mahler 8 9

Further studies in the acid resinification of molasses. Results of tests of molasses tar according to the British Standard specification. Road tests on the construction of molasses road without premetalling. H. D. Sen. *J. Sci. Tech., India* **4**, 65–72(1938); cf. *C. A.* **32**, 8735⁴.—Improvements effected in the process of resinification of molasses with a mixt. of coal tar and asphalt consist of dehydration of molasses to 135°, acidification of dehydrated molasses until the soly. is a min., and resinification with coal tar and asphalt in the presence of acid. Samples of road compn. from molasses of varying consistencies by acid resinification very nearly conform to specifications for road tar from coal tar and petroleum products. Molasses tar macadam roads constructed on hard soils without metalled foundation were satisfactory except under heavy loads. Hard granite stone chips gave the best sustaining power. A. J. Stirton

New wood-impregnating agents. C. Humperdinck. *Arbeitsschutz* **1939**, No. 1, 44–5; *Chimie & industrie* **42**, 271.—A brief discussion of the dangers of intoxication by arsenicals, dinitrophenol, $K_2Cr_2O_7$ and F compds., and of the precautions which should be taken to avoid or minimize them. A. Papineau-Couture

Termite damage: Preventives and remedies. W. J. Baerg. *Arkansas Agr. Expt. Sta., Bull.* **385**, 3–27(1940).—Soil insecticides for the extermination of termites are still in the exptl. stage. Coal-tar creosote mixed with petroleum oil and *o*-dichlorobenzene are recommended as temporarily effective. Lumber treated with coal-tar creosote or $ZnCl_2$ is termite-resistant under some conditions. Termite shields of galvanized sheet Fe or Cu, if properly made and installed, will prevent termites from entering a building. C. R. Fellers

Preservation of timber by the steeping process. R. M. Witka. *U. S. Forest Products Lab.*, Mimeographed Rept. **R621**(1939).—Treatment of wood by long soaking in water solns. of preservative salts in open tanks is described. C. E. Curran

Studies of the osmose process of wood preservation with the use of the disk method. H. Wicht and Bruno Schulze. *Holz Roh u. Werkstoff* **2**, 384–6(1939).—Tests of treated disks show that green wood is more readily treated when colloid pastes are used than with steeping, so that the treating time may be shortened. R. H. Baechler

The preservative treatment of fire-killed mountain ash (E. regnans) and alpine ash (E. gigantea). J. E. Cummins and R. F. Turnbull. *J. Council Sci. Ind. Research* **12**, 294–302(1939).—Details are given of the causes of deterioration of fire-killed timber from a study of two areas contg. mountain ash killed in the 1926 and 1932 fires, and of the conditions favoring the degradation from phys. causes, pin-hole borers and decay. Recommendations are made for the preservative treatment of the felled timber, including end painting of the logs with a mixt. of 8 parts of petroleum jelly and 9 parts of creosote, removal of bark, spraying with creosote, piling for storage either in the open or under cover or by immersion in shallow fresh water. Alfred L. Kammerer

Exposure tests on plywood. Don Brouse. *Mech. Eng.* **60**, 852–6(1938); cf. *C. A.* **32**, 5103⁶.—Joints made with different artificial-resin glues have satisfactorily withstood four years of exposure to severe test conditions. The glues did not appear to soften or hydrolyze on continuous soaking in H_2O, and the joints were unaffected by molds although the presence of the mold-resistant glue line did not protect the wood itself from the action of wood-destroying fungi. After four years of soaking and drying, the specimens still developed a high percentage of wood failure in test. The one vinyl ester included was sufficiently resistant to hydrolysis and mold attack, but lacked the strength required to withstand stresses caused by repeated wetting and drying. Results of previous expts. with older wood-working glues were confirmed, viz., that blood blue contg. pure paraformaldehyde was sufficiently resistant to molds and hydrolysis, but lacked

the strength to withstand indefinitely the mech. stresses set up by repeated wetting and drying, and that casein glues were readily subject to failure from hydrolysis, mold action and mech. stresses when the glue was softened by absorption of H_2O. B. C. P. A.

Proposal for revision of specification for refractories of cement rotary kilns (Committee on Special Refractories) 19. Expts. on protection of wood against fire by use of asbestos cement (Drögsler) 24. Simultaneous production of alumina cement and pig iron in blast furnace (U. S. pat. 2,184,318) 9.

Hoepfner, K. A.: Stand und Aufgaben der Forschung im Teerstrassenbau unter Zusammenwirken von Wissenschaft, Behörden, Industrie und Unternehmertum. Berlin: Allgemeiner Industrie-Verlag Knorre und Co. 38 pp. Reviewed in *Chimie & industrie* **43**, 136(1940).

Cement. Soc. anon. des ciments de Thieu and Leon Blondiau. Brit. 508,736, July 5, 1939. Addn. to 437,855 (*C. A.* **30**, 1971[4]). Cements, particularly slag cement, are obtained in which the constituents of the cement are mixed or ground with gypsum that has been calcined in a slightly reducing atm. at 900–1200°. When rock gypsum is used, the reaction can be made slightly reducing by addn. of 0.5–1% of coal. A rotary tubular kiln is particularly suitable for the calcination of the gypsum and a short period of calcination, e. g., 5–15 min., is preferable to avoid decompn. of the $CaSO_4$. Cf. *C. A.* **32**, 8738[8].

Apparatus for cooling cement clinker, lime, etc. Johan S. Fasting. Brit. 508,500, June 30, 1939. The hot material is supplied to 1 end of, and is distributed from there over the whole length of the mouth of, at least 1 elongated shaft down which it moves under the influence of gravity, and in which at least 1 wall of each shaft is air-permeable, and air is forced through the wall and into the material to cool it. The shafts may be vertical or inclined. The app. may form part of a rotary-kiln plant.

Solidifying and compacting sand, soil, etc. Tiefbau- und Kaltemdustrie-Akt.-Ges. vorm. Gebhardt & Koenig and Hugo Joosten. Ger. 684,769, Dec. 5, 1939 (Cl. 84*c*. 6). A labile ammonia-contg. SiO_2 soln. and a gas that will expel the ammonia from this soln., as air or CO_2 or a mixt. of these, is injected into the mass to be solidified either during or after the introduction of SiO_2 soln.

Road construction. Allison R. Chambers. U. S. 2,183,253, Dec. 12. On a sub-base comprising the subsoil and a water-sol. electrolyte such as NaCl incorporated with it, there is placed a waterproof coating such as tar or asphalt to retain the electrolyte in the sub-base, and a wearing course is placed over this waterproof coating.

Paving. Vincent V. Malcom (to Philip Carey Mfg. Co.). U. S. 2,184,148, Dec. 19. Sections of pavement such as concrete are spaced apart and recesses are provided in adjacent section ends. Compressible material such as cork in granules is used to fill the space between the ends of the sections below the recesses, and waterproofing filling material such as asphalt is poured in place to fill the recesses and remaining space between the sections.

Markings on highway surfaces. James D. French (5% to Vernon Lowrey and John M. Mason). U. S. 2,184,192, Dec. 26. Stripes or the like are formed on the surface of highways by treating a portion of the surface, after laying and while still plastic, with a coloring material comprising an oxide of Fe.

Flooring or pavement comprising rubber. Charles W. Leguillon (to B. F. Goodrich Co.). U. S. 2,184,146, Dec. 19. Paving is formed comprising a pressed body of resilient, slightly flowable, self-healing, permanently unvulcanized rubber compn. contg. a comminuted material, a rigid frame member enclosing the compn., and an open-work metallic reinforcement embedded in the compn. and unattached to the frame member, the frame member having inwardly projecting means overlying the margins of the reinforcement limiting upward movement of the margins.

Forming shingles of laminations of fiber-portland cement composition. John W. Ledeboer (to Keasbey & Mattison Co.). U. S. 2,183,965, Dec. 19. Various mfg details.

Gypsum plasters. National Gypsum Co. Brit. 508,433, June 30, 1939. A set stabilized plaster comprises calcined gypsum, a suitable retarder and inter cake of $NaHSO_4$ in quantity sufficient to stabilize the time of setting when the plaster is gaged with H_2O.

Heat insulation for use in building construction. Richard L. Parish. U. S. 2,183,406, Dec. 12. Sheet units for walls and ceilings are coated on at least one surface with terneplate and on the opposite surface are provided with a closely adherent coating highly reflective to infrared radiation such as bronze, Al or gold leaf. Various structural details are described.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Motor fuels over the world. Gustav Egloff. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 103–13(1939).—A review of the technology of modern motor fuels. The use of alc. as a substitute for gasoline was declared economically and mechanically troublesome. NH_3, H_2, C_2H_2 and coal dust were also considered as motor fuels.
J. H. Reedy

Native liquid motor fuels. Erik Hägglund. *Svensk Papperstidn.* **42**, 488–90(1939).—Benzine and motor alc. (from waste sulfite liquor) are compared as to prepn., and use as motor fuels separately and in mixts. with each other. Wilhelm Segerblom

Relation of Diesel fuel properties to their engine performance. W. S. Mount and G. A. Hope. *S. A. E. Journal* **46**, 100–5, 136T(1940).—Performance tests of 12 Diesel fuels of 20–80 cetane no. under a variety of operating conditions were made. Only slight gain is obtained from use of cetane nos. higher than needed to prevent misfiring.
H. A. Beatty

Vegetable oils as Diesel motor fuel. B. Ilev. *Ann. univ. Sofia, V. Faculté agron. sylvicult.*, Livre **1**, 15, 146–84(1937); *Chem. Zentr.* **1938, II**, 3494.—Tests made with sunflower oil and castor oil as fuels in a one-cylinder Diesel motor (Wichterle Kovarik, Czechoslovakia) are reported. The fuel consumption was about the same for sunflower oil as for petroleum fuels. The motor could not be started with a hand crank. Either a petroleum fuel or a mixt. of the sunflower oil and such fuel must be used to start the motor. Since sunflower oil belongs to the semi-drying oils, it is necessary to introduce a mineral oil fuel again before shutting off the motor. A slight addn. of alc. (3–5%) also has a beneficial effect. Castor oil was tested only in mixts. with alc. For such mixts. the fuel consumption was greater than that for sunflower oil. No essential change in the fuel consumption resulted from increasing the alc. content from 5 to 30%. The annual production of sunflower oil is 190 kg./ha.; that of castor oil 400–500 kg./ha. of field area. M. G. Moore

The use of selective solvents for improving the quality of lignite motor fuels for use in Diesel motors. M. Marder. *Mitt. Ges. Brankohlen- u. Mineralolforsch. Tech Hochschule Berlin* No. **12**, 46–8(1936); *Chem. Zentr.* **1938, I**, 4559.—Oils of excellent quality are obtained by the treatment of lignite tar oils with selective solvents. With Diesel motor fuels especially, ease of starting (the motor), stability during storage, odor and color are improved. Through the removal of resinous and asphaltic compds. as well as corrosive S and O compds. in the ext., the corrosive action of the fuel and the tendency to carbonize are reduced. The efficiency of phenol, alc., furfural,

liquid SO_2, benzene, nitrobenzene, cresol, pentane, acetone, crotonaldehyde and Chlorex as selective solvents for the refining of lignite tar oils was tested. The improvement in quality was measured by a comparison of analytical data and data from motor operation for the original oils with the same data for the refined product. By altering the amts. of the solvents used, oils of the desired quality and properties can be obtained. M. G. Moore

Gas as a [motor] fuel. J. S. Clarke. *Automobile Engr.* **30**, 8–10(1940).—An exptl. spark-ignition engine run on city gas at 1.5 : 1 compression ratio compared favorably with Diesel engines in economy and power developed. A. O. Allen

Liquid ammonia as a substitute motor fuel. G. Benoist. *Rev. carburants franç.* **1**, 349–54(1938).—H obtained by decompn. of liquid NH_3 by means of a special catalyst is used with gaseous NH_3 and employed as a motor fuel. The fuel wt. carried, including tank, is 1.3 lb./h. p.-hr. as compared with 0.65 lb./h. p.-hr. for gasoline. B. C. P. A.

Composition of Italian bituminous rocks and their utilization for production of liquid fuels. F. Roma. *Il Calore* **10**, 265–86(1937).—Italy's oil-shale resources are reviewed. A new oven designed by the author for extg. oil from bituminous rocks is diagrammatically described. A stream of gas heated to 500° is continuously circulated past the heated material in the oven and the extd. oil is condensed. The following yields per ton were obtained by treating Abruzzo rock contg. 11.7% of bitumen: oil extn. 80%, residual combustible material 0.9%, heat consumption 130,000 kg.-cal., current consumption 10.8 kw. B. C. P. A.

Calculation of heat of combustion of solid and liquid fuels from calorific values of their constituents. R. Michel. *Feuerungstech.* **26**, 273–8(1938).—The heat of combustion of C atoms in compds. is less than that of C in the free state. A method of calcn. is developed whereby the calorific value of the constituents of an org. substance can be deduced from its ultimate analysis. The method is applied to the calcn. of the calorific value of the C atom in coal. The energy of the C atom not combined with O in bituminous and brown coals is greater than the heat of combustion of elementary C in the solid phase. There is no universal formula for calcg. the heat of combustion of all qualities of coal. The appropriate formula is detd. for C calorific values from 95 to 100 kg.-cal., and a nomogram is given for constructing corresponding formulas for other pertinent calorific values. B. C. P. A.

Failure of the producer-gas vehicle on the continent. Ernest W. Steinitz. *Petroleum Times* **42**, 485–6(1939).—If charcoal is used for fuel for the producer-gas generator and if by means of a steam generator the gas is enriched with H_2, its calorific value is still no more than 130–138 B. t. u. per cu. ft. The starting operation is complicated and difficult; and a truck cannot be driven with the accelerator pedal alone because the compn. of the gas is constantly changing with engine speed and load. Operation with anthracite, low-temp. coke or, especially, lignite coke is still more troublesome. Emma E. Crandal

Some chemical changes in coal samples during storage. O. W. Rees and M. L. Kalinowski. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 120–1(1939).—Samples of coal stored 4½ yrs. at 30 32°F. showed an av. loss in B. t. us. of 2.29% and a gain in sulfate S of 330%. The loss in fuel value during storage seems to decrease as the ratio of fixed C to volatile matter increases. J. H. Reedy

A formula for calculating the calorific value of Japanese coals. Takasi Arai. *J. Japan. Ceram. Assoc.* **47**, 343–6(1939).—The calorific power Q is calcd. approx. from $Q = F[100 - (A + M)]$, where A and M are percentages of ash and moisture, resp., in the coal and F is a variable factor. For bituminous coal whose fuel ratio or fixed carbon/volatile matter is 1 to 4, when moisture content of coal is 0 to 2%, 2 to 4%, and 4 to 6%, F is 89 − 2.5 M, 88–2.0 M, and 86–1.5 M, resp. For brown coal whose fuel ratio is less than 1, when moisture content is 0 to 4% and 4 to 6%, F is 87–2.0 M and 81–1.5 M, resp. The calcd. values agree within 5% of those obtained by Mahler's bomb calorimeter. S. Kondo

Coal-washing processes employing suspensions of dense media. Henry Verdinne. *Colliery Guardian* **159**, 667–70, 711–15, 747–50, 787–8(1939).—In these processes the raw coal is divided up in accordance with the sp. gr. without the help of dynamic means. In general, a bath of one shape or another is employed which is equipped with the necessary handling gear for removing the 2 or 3 sepd. products. The suspensions used in coal washing are composed of a liquid suspending medium (as water) and of a finely divided solid which does not react with the liquid. An essential characteristic of the system is that it possesses stability. If the solids are ground sufficiently finely the suspension becomes more or less stable and remains so for some time. This has the practical drawback that after use the recovery of the suspension is very slow and costly. For this reason it is generally preferable to use more coarsely divided medium and to resort to some other method to obtain the desired degree of stability. In the Chance process particles of sand (0.2 to 0.5 mm.) are kept in suspension by means of an upward current, which in practice is augmented by the action of a system of slowly rotating paddles. In the de Vooys process which employs barites the diam. of the particles is approx. 0.05 mm. The stability of the suspension is effected by the addn. of a protective colloid, in this case clay. The presence of the colloid increases the viscosity of the suspension and slows down the sepn. of the constituent particles of the raw coal. In practice it is necessary to control both the viscosity and d. of the suspension between fairly narrow limits; this is done by limiting the percentage of solid material in the suspension and by heating the medium to about 35°. The Loess washing method developed at the Dutch State Mines resembles the de Vooys process because clay is present in the natural material; the particles are about 0.5 mm. in size; this suspension has a uniform d. which is maintained without the use of upward currents. The suspensions in all 3 of the above processes have a uniform d. from top to bottom of the bath. The Tromp process employs a suspension of magnetite (sp. gr. 4–8) which is ground to pass 0.1 mm. The suspension is not stable and no attempt is made to prevent the natural sedimentation of the particles of magnetite, the d. increasing from top to bottom of the bath. The d. selected for the sepn. between the clean coal and the middlings on the one hand, and between the middlings and the shale on the other are maintained at const. values by the return and remixing of the heavy medium withdrawn from the bath at various levels. I. Hartmann

Specific-gravity coal washing with special reference to the Tromp process. C. W. H. Holmes. *Colliery Guardian* **159**, 861–4, 899–902(1939).—The sp.-gr. processes can be divided into those that employ a high-density liquid and those in which a suspension of heavy, finely divided material in water is employed. This paper is concerned only with latter processes. The suspensions that can be used are grouped into stable and unstable types. Stability can be obtained in the following ways: (1) by the selection of a solid medium which is naturally stable over a useful range of sp. gr. (as in the Loess and Wuench processes); (2) by means of rising currents (Chance process); (3) by mech. agitation; (4) by the addn. of some stabilizing agent that will procure the desired stability without at the same time raising the viscosity to such an extent as to prohibit its use (clay in the de Vooys process). The Tromp process is the only one that purposely employs an unstable suspension; the solid media that have been used are magnetite and burnt pyrites, chiefly the former. The instability of the medium must be controlled and the initial control consists in first deciding on the approx. densities that are required at the top and bottom layers of the suspension, and prepg. the magnetite by regulating the grinding time for each batch of raw material to give the necessary degree of fineness that will in turn give the required rate of settlement. In this process the raw coal is fed to a bath and falls beneath the surface of the suspension, the clean coal floats up to the

surface and is continuously removed by a scraper over an inclined slot screen; the refuse sinks through the suspension and is extd. through a drain. Particles of intermediate d. are continuously moved across the bath by means of slow horizontal currents of suspension and are finally extd. with another scraper, together with a certain amt. of suspension. The circulation of the streams of heavy medium is effected by means of air lifts, and arrangements are made for mixing the circulations to obtain the desired densities at various levels. The process is claimed to have the following advantages over the use of jigs: higher yield of washed coal for an equiv. ash content; ash content of washed product is more uniform; increased yield of screened sizes owing to decreased breakage during washing; absence of degradation. I. Hartmann

Preparation of humic acids from Illinois coals. G. R. Yohe and C. A. Harman. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 134–6(1939). Humic acids were prepd. from the banded ingredients (durain, clarain and vitrain) of Illinois coal by dry-air oxidation at 150° for 3 weeks. The humic acids were extd. by 5% NaOH and repptd. by HCl. They were also prepd. by bubbling air through an NaOH suspension of coal at about 95°, and repptg. as before. The dry-air oxidation gave better yields, was more convenient, and the results were more reproducible. Vitrain (obtained by a float-sink separation) can be converted almost completely into humic acid (yields of 96%), while durain and clarain (prepd. by hand picking at the mine) gave yields of 60–80%. J. H. Reedy

Pyrite from bituminous German coal. F. Kolbe. *Brennstoff-Chem.* **19**, 373(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 276. By a suitable modification of the washing process (described), which however, requires considerable space and much water, slimes contg. up to 85% pyrite are obtained. A dry method involving wind-sifting, and electrostatic and magnetic methods also deserve consideration. C. A. Silberrad

The influence of benzene-pressure-soluble bitumens on the carbonization and gasification behavior of bituminous coal. Otto Rossow. *Braunkohlenarch.* No. **51**, 3–32 (1939).—Extn. app. is shown and procedure described wherein a series of 5 coking (*A*), 3 gas (*B*), and 4 free-burning (*C*) coals were repeatedly extd. with C_6H_6 by the method of Fischer. Cokes prepd. from extd. coals, unlike those made from the original coals, could not be classified according to properties which differed little. Examn. of gas fractions obtained in the gasification test of Dolch showed that the original coals yielded more gas to 550°, contg. more hydrocarbons, more CH_4, of higher calorific value and total gas B. t. u. than did the same fractions from the extd. coals. The 550–1100° fractions likewise were larger from the original coals but the results of compn. comparisons and the influence of bitumens were not entirely clear. Less cracking is indicated by compn. of the gas from the extd. coals. With coals *A* and *B*, gas B. t. u. decreased 20%, with *C* coals 15%. Study of the bitumens extd. showed their coking residue and tar increase with decreasing volatile matter while gas increased with increasing volatile matter. Properties as fixed C and volatile matter paralleled those of the original coals; gasification balances also confirmed this. Further examn. included detn. of the solid and oily fractions, flow and drop points, all without characteristic relation to either coke, tar or gas formation. Mixts. of residual coal with added bitumen exhibited 50–60% recovery of caking and swelling properties with the *A* and *B* coals in Schroth cakability tests and in swelling tests at 700–1100°. With the *C* coals, these tests were neg. as before. Residual coals mixed with petroleum pitches and resins gave results similar to those produced by bitumens, caking and swelling increasing with increasing admixt. but not attaining the values for the original *A* and *B* coals. With *C* coals the values for swelling exceeded those of the original coals. Conclusions: Bitumens favor melting processes of the coal substance and support the hypothesis of coke formation. The principal portion of the bitumen, without regard to origin, but in its distribution in the coal together with the specific nature of the residual coal, dets. the nature of the coke formed. 29 references. F. W. J.

Viscosity of coal-ash slags. P. Nicholls and W. T. Reid. *Trans. Am. Soc. Mech. Engrs.* **62**, 141–53(1940).—Relatively few coal-ash slags have the melting characteristics of glasses; for most ash compns. there is a distinct liquidus point. Preliminary viscosity-compn. diagrams for coal-ash slags melted in air are given at temps. of 1538, 1427, 1316, and 1204°; the liquidus lines are indicated at each temp. It is suggested that when complete diagrams become available accurate predictions can be made on the effect of mixing the ash of 2 coals or of the addn. of the main constituents. The authors emphasize that predictions of the relative fusion and clinkering characteristics of coals from the cone softening temps. may give erroneous comparisons, but that the initial and fluid temps. can be some addnl. guide. I. Hartmann

Swelling behavior of brown coals. Weather stability of brown-coal briquets. Karl Fritzsche. *Braunkohlenarch.* No. **52**, 3–44(1939).—The literature is reviewed in its bearings on the problem; causes and possibilities of lessening weather instability were investigated. Lab. app. and the procedure used for the rapid detn. of stability by H_2O uptake are described. Data for briquets originating in 4 districts are presented. The effect of pretreatment of the highly swellable Upper Geiseltal brown coal with 10% HCl, H_2SO_4 and H_2SO_3, drying and steam treatment on the briquets was detd. Likewise, effects of drying, heating, and moistening were correlated with factors as time, particle size, bitumen content and position in the coal seam. Tech. app. for these treatments is described together with effects of factors encountered in industrial application. It is concluded that causes of weather stability are not in org. admixts. or bitumen content but in coal compn. which is dependent upon genesis of the coal in Ca-rich localities. 41 references. F. W. J.

How is the degree of decomposition and of processing of crude peat to be determined? S. I. Sidyakin. *Za Torfyanuyu Ind.* **1937**, No. 12, 20; *Chem. Zentr.* **1938**, I, 4257.—The degree of turbidity that remains when an aq. peat suspension is allowed to stand can be used for estg. the degree of decompn. of the peat and the extent to which it is influenced by the processes employed in working up the material. The water content and viscosity of the sediment are also of value in this connection. M. G. Moore

The gas industry in Switzerland. W. Tobler. *Schweiz. Ver. Gas- u. Wasserfach., Monats-Bull.* **19**, 217–23(1939); cf. *C. A.* **33**, 6560⁸.—A review of nearly 100 years of Swiss gas industry. B. J. C. van der Hoeven

Natural gas and petroleum in the Languedoc. V. Charrin. *J. usines gaz* **56**, 499–501(1939).—The only source of natural gas in quantities sufficient for use is in the Buisin valley (Ain). Besides these the presence of natural gas in other parts is suspected, such as in the Languedoc range. At Gabian (Herault) little hydrocarbon gas was found, but CO_2 instead, borings at Castelnau were dry down to 1000 m., likewise at Bauquinies. So far a boring at Pic Saint Loup down to 1000 m. has not shown any sign of gas or oil. B. J. C. van der Hoeven

Experiences in gas purification. W. L. Ashdown and C. K. Cornilsen. *Water Works & Sewerage* **86**, 250–2 (1939).—An Fe oxide scrubber is used to remove the H_2S. W. A. Moore

Gasification of Italian fuels by means of oxygen. G. Natta and R. Rigamonti. *Atti X° congr. intern. chim.* **4**, 312–19(1939).—The results of continuous retorting on a semi-industrial scale of coal, lignite, etc., contg. volatile matter by means of mixts. of O_2 and steam, according to a process first applied to coal poor in volatile substances, are summarized. The process in one case led to the production of a very pure water gas most suitable for chem. syntheses (methanol, higher alcs., Fischer gasoline, etc.), for conversion and for the production of H_2, and synthetic NH_3. A. H. Krappe

Autothermal conversion of water gas. I. Lavrent'ev. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 16–23(1939).—Equations are derived for calcg. and controlling the heat

relations of the H_2O-heating tower and the gas-satn. tower. The calcns. of Usyukin (*C. A.* **33**, 1471[8]) are criticized. H. M. Leicester

Generation of water gas and synthesis gas from brown coal, peat, and bituminous coal in the Pintsch-Hillebrand plant at the Hamburg gas works. Friedrich Stief. *Gas- u. Wasserfach* **83**, 1–6(1940).—Present German endeavors are to increase the quantity of gas by dilg. coal gas with water gas. The cheapest source of this gas is the Pintsch-Hillebrand continuous water-gas generator, using brown coal (*C. A.* **30**, 6937[8]). Improvements were made in this generator so that it has been possible to operate continuously and shut down the regular (coke) water-gas plant. One advantage of this process is the reduced content of org. S and H_2S in the gas, owing to the reforming of the carbonization products by passage through the generator fuel bed. The most important change has been to use producer gas for heating the regenerators, with the burners at the top of the regenerators. The length of time that the regenerators are used for heating the circulating gas has also been increased. Tar yields are about $^2/_3$ of that indicated by the Fischer retort test. The best fuel is brown coal, preferably in briquet form. This coal should not have too high an ash content, too low an ash m. p., and the ash should not react with the refractories. Good results were also secured with peat (*C. A.* **34**, 609[2]). Bituminous coal (high volatile) was also tested, but its low reactivity did not permit complete gasification. If certain changes in construction were made, it should be possible to use this coal but it would be necessary to use the resultant high-ash coke in gas producers. R. W. Ryan

Propane and butane as domestic fuel gases. G. Dall'Ara. *Atti X° congr. intern. chim.* **4**, 697–704(1939).—The practical and economic aspect of the use of propane and butane as domestic fuel gases is stressed, with special reference to Italian rural households. A. H. Krappe

The reaction between methane and steam. Toyoziro Ogura and Tosio Huzimura. *J. Chem. Soc. Japan* **60**, 139–48(1939); cf. *C. A.* **30**, 1542[8].—The reaction $CH_4 + 2H_2O = CO_2 + 4H_2 - 38.5$ cal. was studied with natural gas contg. CH_4 95.2, C_2H_6 1.9, CO_2 1.6, C_nH_m 0.3, air 1.0%. For this reaction a catalyst is necessary. With an effective catalyst the reaction is completed at 550–600°. $H_2O:CH_4 = 7$ to 10 is the best ratio. Ni is the best catalyst: However, if it is used alone its catalytic activity decreases at higher temp. (700°) owing to its melting. Addn. of a promotor prevents this inactivation. With Al_2O_3 as promotor, $Ni:Al_2O_3 = 1:0.025$ in mols. gives the greatest activity. Addn. of a minute amt. of alkali does not affect the catalytic activity but decreases the durability of the catalyst. Concn. of the catalyst 10%, particle size 3–4 mm., contact period 25–30 sec. are recommended. Temps. below 700° for the roasting and below 300° for the reduction give the best catalyst. A Ni-Al_2O_3-kaolin catalyst prepd. according to these observations gave good results in an expt. lasting 150 hrs. K. Shinohara

The yield of gas during coking depending on the content of volatile substances in coal and in coal mixtures. S. G. Aronov and B. I. Kustov. *Coke and Chem.* (U. S. S. R.) **1938**, No. 2, 17–20; *Khim. Referat. Zhur.* **2**, No. 5, 97 (1939).—The compn. of gas obtained from different coals varied widely The heat content of gases varied directly with the content of volatile substances in coal. The yield of gas from coals contg. 22–4% of volatile substances varied between 300 and 315 cu. m. (with a standard heating value of 4000 cal./cu. m.). An increase of the volatile substances by 1.6–3.8% caused an 8–10% increase of the yield of gas. W. R. Henn

Drying and cleaning [coke-oven] gas by refrigeration. W. Niebergall. *Z. Ver. deut. Ing.* **82**, 1423–8(1938).—Recent developments in the sepn. of H_2O and $C_{10}H_8$ by refrigeration are reviewed. B. C. P. A.

Corrosion in gas systems and consequent disturbances. Leopold Kaatz. *Gas- u. Wasserfach* **83**, 17–21(1940).—A questionnaire relative to causes of, and consequences from, corrosion was submitted to 3 large German gas companies. The compn. of the mixed coal-water gas and that of the water gas was given for each of the companies. Variations of the gas compn. during the day or month were as high as 3%. The heating value of the mixed gas was 440 to 450 B. t. u. per cu. ft. Carbonizing equipment included horizontal, inclined and vertical retorts (and ovens?), and a wide variety of coal was used. Only one company removed HCN, and none dried the gas. All of the plants used dry S purification and oil absorption for light oil recovery, except that one company had a small active C plant. The residual light oil content varied from 1 to 5 g. per 100 cu. m. and the org.-S content after oil scrubbing was 6 to 8 grains per 100 cu. ft. Difficulties were encountered with stopcocks and valves due to (1) rust, plus fatty constituents, (2) condensate and (3) gum. These difficulties were minimized by the use of special lubricants. One company had trouble with sluggish diaphragms and sticking valves in house governors, another vent-line stoppages, fouled valves and deterioration of rubber. Still another had naphthalene stoppages. Gas-meter difficulties were attributed to rust, tar, sticking of valves and condensate; provision was made for oiling valves. Corrosion was encountered with wet-drum meters. Practice in covering service pipes was reviewed. The larger part of the distribution systems were steel. Tar and gum deposits were found near the works by one company and in drips, governors and pilots by another. Naphthalene content of the gas varied from 1.2 to 5 grains per 100 cu. ft. and but little difficulty was encountered with naphthalene stoppages. Rust deposits varied in color in the 3 systems (this was due in part to cyanide content). Tar deposits generally occurred at the same point as rust, and were largely sol. in benzene. Internal asphalt coatings of mains were frequently dissolved. Internal corrosion of the mains coincided with condensate formation in both cast iron and steel mains. R. W. Ryan

The bases of dry removal of hydrogen sulfide from coal gas. H. Brückner. *Atti X° congr. intern. chim.* **4**, 289–304(1939).—Of the purification methods for the crude gas, the dry process with $Fe_2O_3.xH_2O$ is still the most widely used. Its efficiency depends on the H_2O content of the material, the reaction temp., and the structure of the hydrate. Most suitable are cryst. hydrates, especially bauxite residue. The reaction velocity of the natural hydrates is much smaller, partly owing to the effect of humic acids. A rational arrangement of the process also permits complete removal of NO compds. from the gas; thus prevents the occurrence of resinous deposits. A. H. Krappe

Clarifying gas-holder waters. J. J. O'Loughlin. *Gas Age* **84**, No. 12, 19–20(1939).—When a water-sealed water-gas holder contained some coal gas, and steam was injected into the sealing water to prevent freezing, a white, milky ppt. formed. After some time a white resinous coating appeared on the tank surfaces which were in contact with the water. This white deposit, at places 0.25 in. in thickness, was a pptd. emulsion of naphthalene. The milky condition can be successfully treated by addn. of 100 p. p. m. of neutralizing alkali, changing the pH from 6.1 to 8.9. The addn. of 830 p. p. m. of $FeCl_3.6H_2O$ (pH 2.8) and 670 p. p. m. of an alkali precipitant resulted in a final pH of 10.2. The milky material was adsorbed and settled out by the ferric ppt. During the addn. of these reagents the aq. soln. was well mixed by mech. or gas agitation. H. E. Messmore

Production of two grades of benzene by the method of fractional condensation. M. Z. Litvin and M. B. Khvat. *Coke and Chem.* (U. S. S. R.) **1938**, No. 12, 23–7; *Khim. Referat. Zhur.* **2**, No. 5, 97(1939).—Light benzene leaving the dephlegmator at 85–90° contained 94–7% of the fraction b. up to 160° and 4% of the fraction b. up to 180°. The yield of the heavy benzene was 6–18% of the wt. of the crude benzene remaining after distilling off the fraction up to 180°. The coumarone resin was of high quality, clear, of amber color and softened at 82°. It amounted to 7.5–11% of the heavy benzene. The equipment for the process is described. Refluxing produced only a slight improvement in the quality of benzene. W. R. Henn

Tentative equilibrium constants for light hydrocarbons. B. H. Sage, B. L. Hicks and W. N. Lacey. *Refiner Natural Gasoline Mfr.* **17**, 350-8(1938).—Available data relating to the equilibrium consts. of light hydrocarbons (CH_4, C_2H_6, C_3H_8, etc.) under the conditions of temp. and pressure encountered in the production of petroleum from underground reservoirs are correlated. B. C. P. A.

The determination of the carbon dioxide content of ammoniacal liquors. F. N. Astley and H. D. Greenwood. *J. Soc. Chem. Ind.* **58**, 251-2(1939).—Of a concd. gas liquor, take 25 cc. dil. to exactly 250 cc. and add 5 cc. of NH_4OH. Titrate 10 ml. of this soln. with *N* HCl to a methyl orange end point. Transfer another 10 cc. of the soln. to a 250-cc. flask contg. some distd. water, add 25 cc. of 10% $BaCl_2$ soln. while shaking, and make up to the mark. If a clear soln. does not result in 10 min. add 1 g. of NH_4Cl to accelerate coagulation of $BaCO_3$. Filter and titrate 200 cc. of the filtrate with *N* HCl. Satisfactory detns. can be carried out on liquors contg. 2 27% CO_2. R. E. Reeves

Methods of working up coal-tar pitch. L. D. Gluzman, S. M. Grigor'ev and V. N. Khavlzhnov. *Coke and Chem.* (U. S. S. R.) **7**, No. 11, 50-5(1937); *Chem. Zentr.* **1938, II**, 3492. A general review of the possibilities of recovery and use of compds. occurring in coal-tar pitch. M. G. Moore

The hydrogenation cracking of tars. V. The operation of a semitechnical-scale plant. C. M. Cawley and J. G. King. *Dept. Sci. Ind. Research* (Brit.), *Fuel Research, Tech. Paper* No. **51**, 36 pp.(1939); cf. *C. A.* **29**, 6024[2,8]; **32**, 1074[7], 9448[8]. The design, operation and control of the plant and the phys. and chem. results obtained are described. The purpose of the work was to det. whether and in what manner the results obtained in the small-scale expts. would be influenced by expansion to large-scale operation. The plant was erected for the treatment of 200 to 400 gal. of raw material per day at 200 atm. pressure or of considerably higher throughput at 400 atm. pressure. The ratio of H to tar or oil is 200-500 cu. ft. per gallon and of this about 100 cu. ft. per gallon takes part in the reaction while the remainder is recirculated. Low-temp. tar (sp. gr. 1.061 to 1.068), made in narrow brick retorts, was used for making up the various raw materials; the tar is mixed with "recycle oil." The raw material received no treatment before use except filtration and the soln. of 0.5% S in a recycle oil which was to be used alone; the presence of S was essential to obtain the full activity of the Mo catalyst. The products obtained in the plant indicate that results similar to those in the exptl. scale plants can be obtained when certain known differences in the raw materials used are taken into consideration. 10 references. I. Hartmann

Combustion of coke. M. K. Venstrem. *J. Tech. Phys.* (U. S. S. R.) **9**, 1592-603(1939). It is shown by calcn. that in the reduction zone the surface of coke is cooled down by the reaction $CO_2 + C = 2CO$; the temp. of chemically active coke may be several hundred degrees below that of the combustion gases. Water cools coke like CO_2. In another layer of coke the oxidation of CO by O_2 is the preponderant reaction. In this layer O_2 is consumed before it reaches the surface of coke, and the temp. of the gas adjacent to coke is higher than those of coke and of gases further from its surface. The gasification of coke in this layer is faster than in the reduction zone since the gases contain more CO_2 and the rate of diffusion of CO_2 to the surface of coke is higher. J. J. Bikerman

The British by-product coking industry. G. E. Foxwell. *Iron & Coal Trades Rev.* **140**, 115-16(1940).—The present economic position of the industry is examd., possible future developments in connection with by-products discussed, and closer coöperation urged between this industry and the gas industry. New oven construction during the past year is referred to and the question of modernization is treated. I. Hartmann

Development of the by-product coke oven. T. A. Long. *Iron & Coal Trades Rev.* **140**, 120, 161(1940).—Brief review of developments taking place since the by-product coke oven was introduced in Great Britain. I. Hartmann

Improved operation of oven producers. G. Alliata. *Schweiz. Ver. Gas- u. Wasserfach., Monats-Bull.* **19**, 223-4 (1939).—Regulation of the operating conditions in a built-in producer is brought about by using forced draft instead of natural draft. Variations in resistance of the firebed no longer affect the primary air vol. appreciably. B. J. C. van der Hoeven

Handbuch der Gasindustrie. Bd. III. Gasreinigung und Nebenproduktengewinnung. Edited by **Horst Brückner**. Munich: R. Oldenbourg. 635 pp. M. 48. Cf. *C. A.* **33**, 1174[9].

Fuels. I. G. Farbenindustrie A.-G. Brit. 508,482, June 30, 1939. Pulverulent fuels that do not melt or have high m. ps. are produced from oleiferous substances contg. high-boiling substances rich in H along with high-boiling asphaltic constituents poor in H (e. g., the products obtainable from coals rich in bitumen such as brown coals from central Germany, or from Brazilian or South African oil shales, by pressure hydrogenation with small amts. of H, or by extn. in known manner, or also tars, such as brown coal product tar, or asphalt-basic petroleums) by sepg. from the initial materials by treatment with selective solvents, e. g., propane, butane, pentane, hexane, the asphaltic substances and allowing oxides of N, or compds. yielding the same, e. g., HNO_3, to act on the asphaltic substances, preferably in ground state. Wax-like substances practically free from asphalt are obtained as a by-product. Treatment of the asphatic substances with the oxides of N may be conducted simultaneously with their communition in a grinding app.

Apparatus for the destructive distillation or partial carbonization of materials carbonizable at low temperatures David Kainscop. Brit. 508,782, July 3, 1939. The app. comprises a continuous oven with 2 hearths arranged 1 above the other and heated in countercurrent, the carbonizable material, which enters the oven with its natural humidity, traveling first on the upper hearth, which serves for heating and drying, and then on the lower which serves for distn., as a relatively thick layer (approx. 50 mm.) that is constantly turned over by a means comprising endless chains guided laterally and supporting cross members on which oscillate freely independent shovels, which tilt in opposite directions on the 2 hearths so that their shafts take, of their own accord, opposite inclinations on the hearths and which are completely embedded in and always rake the material that collects in heaps against the bank formed by the blades of the shovels. The steam freed from the fresh material during drying mixes with the distd. hydrocarbons to prevent decompn. of the latter.

Apparatus for carbonizing material. Humphreys & Glasgow Ltd. and Eric C. Mengel. Brit. 508,780, July 4, 1939. Divided on 506,994 (*C. A.* **34**, 2457). App. wherein heated gases are circulated through the material to effect carbonization, is provided, in a circuit through which gases leaving the vessel contg. the material pass, with a baffle box or dust catcher so situated in the off-take pipe from the carbonizing chamber that pitch and tarry vapors are not deposited and trapped therein but are left for subsequent removal in the system. A heavy tar trapping-vessel or seal pot, a condensing unit, e. g.,

primary and secondary condensers, and a cyclone separator intermediate of the baffle box or dust catcher and a gas-circulating fan, the arrangement being such that the pitch and tarry vapors are gradually eliminated, are also provided.

Hydrocarbons from carbon monoxide and hydrogen. Wilhelm Michael and Wolfgang Jaeckh (to I. G. Farbenind. A.-G.). U. S. 2,183,145, Dec. 12. Conversion is effected (suitably at a temp. of about 280-360° under 12 atm. pressure) with use of a catalyst prepd. by a thermal treatment of an Fe compd. such as pptd. Fe hydroxide at a temp. above 600° and in the presence of a reducing gas such as H but below the m. p. of the Fe compd. or that of the Fe produced in the treatment, the temp. employed being sufficiently high to effect at least partial sintering of the product. U. S. 2,183,146 relates to a like process in which the catalyst used is prepd. by heating a carbonyl compd. such as that of Fe to such a temp. above 500° as to effect decompn. and at least partial sintering.

Operations such as dewatering coal. Geo. H. Rupp and Philip M. Frantz (to Colorado Fuel and Iron Corp.). U. S. 2,183,896, Dec. 19. App. is described, and a method of sepg. particles of coal, etc., from a liquid with which they are mixed, which comprises the introduction of such a mixt. into a suspended pool confined at its sides and supported on its bottom by an inclined filtering medium, producing an ungraded settling of particles in the pool by the discharge of the liquid content through the filtering medium by subjecting the pool to differential vibratory impulses directed in opposition to the inertia of such pool at approximately 45° to the inclined bottom, compacting the settled solids on the filtering medium in ungraded condition by a continuance of such vibratory impulses, and entrapping solids, inclusive of fines, in the compacted body during its movement along the inclination of the filtering medium upwardly out of the pool induced by repetitions of the vibratory impulses.

Dehydrating lignite. Eugene P. Schoch. U. S. 2,183,924, Dec. 19. A process of dehydrating lignite comprises submerging raw lignite as obtained from a mine under a hydrocarbon oil of which a substantial fraction has distn. temps. higher than water, within a closed vessel capable of standing the resulting high vapor pressure; heating this closed vessel and its contents to a temp. above the vaporization point of the water in the lignite while allowing no substantial amt. of water vapor to escape but retaining it until a desired max. temp. is attained; then allowing any desired portion of the moisture from the lignite to be blown off while the charge is at such a high temp. and while it is still submerged under and is being heated by the oil; and draining off the remaining liquid oil from the lignite.

Treating gaseous hydrocarbon mixtures such as natural or still gases. Arthur J. L. Hutchinson (to Fluor Corp., Ltd.). U. S. 2,184,596, Dec. 26. An arrangement of app. is described, and a process which involves flowing a stream of relatively light and heavy gaseous hydrocarbons through an absorption medium to ext. therefrom hydrocarbons liquefiable at the operating temps. and pressures, distg. the mixt. to remove the absorbed hydrocarbons, condensing removed hydrocarbons, stabilizing the condensed hydrocarbons, and adding a portion of the stabilized hydrocarbons in cooled and liquid form to the hydrocarbons undergoing condensation to increase the ratio of the liquefied heavier constituents to the liquefiable lighter constituents with respect to their ratio in the absorption medium prior to distn.

Water gas. Humphreys & Glasgow Ltd. and Joseph H. Smith. Brit. 508,617, July 4, 1939. In a cyclic process wherein an ignited fuel bed is alternately blasted with air and steamed, purging of the set after blasting of the fuel bed with air is effected by first admitting steam for a very short period at the base of the generator and burning the resulting water gas and expelled blast products in the regenerator or recuperator and waste-heat boiler and thereafter, as soon as the gas leaving the generator is sufficiently low in N, steam is admitted between the generator and regenerator or recuperator so that the waste gases in the set beyond the point of steam admission are expelled to atm. by steam alone without waste of water gas. To avoid contamination of water gas left in the plant by blast gases being used to displace the water gas into the gas holder, the operating cycle is arranged so that the gas-making period is terminated by a backrun, which leaves the spaces in the plant beyond the generator filled with steam, and thereafter steam is admitted to the generator base for just so long as to displace the water gas beneath the grate, any water gas then remaining in the generator being at the commencement of the blow burned in the regenerator or recuperator to store its heat, and the displaced steam and the small quantity of products of combustion of the water gas that are left in the generator are discharged to atm. App. is described. Brit. 508,618, July 4, 1939, describes a cyclic process in which an ignited fuel bed is alternately blasted with air and steamed, the gas-making or run period comprising 2 or more short down- or back-runs sepd. from each other by an interposed up-run to reduce the temp. of the gases leaving the plant during the up-runs and to maintain the lower ash and clinker above the temp. of steam condensation.

Carbureted water gas of high British thermal unit. Leon E. Osmer and Wm. Tiddy (to Semet-Solvay Engineering Corp.). U. S. 2,183,845, Dec. 19. An arrangement of app. is described, and a process of making high B. t. u. carbureted water gas suitable for use as a substitute for natural gas in a set comprising a generator contg. a bed of fuel therein, a carburetor connected with the generator, and a superheater contg. checkerbrick and connected with the carburetor, which comprises the following steps: (*a*) blasting the fuel bed with air and burning the resultant blast gases in the carburetor and superheater to heat these chambers; (*b*) discontinuing the blasting cycle, passing steam up through the fuel bed and passing the resultant water gas into the base portion of the carburetor up therethrough, while simultaneously introducing hydrocarbon oil into the water gas to carburet the water gas, passing the mixt. of oil gas and water gas through the superheater to fix the carbureted water gas and to produce a gas of a B. t. u. content approx. equal to that of natural gas; (*c*) discontinuing the carbureted water-gas-making step and passing steam down through the fuel bed, introducing the resultant water gas into the carburetor, adding secondary air to the water gas to support combustion thereof, and burning the water gas as it passes through the carburetor and superheater to heat these chambers to a temp. suitable for effectively cracking gas oil; (*d*) discontinuing step (*c*) and passing steam down through the fuel bed, introducing the resultant water gas into the base of the carburetor, introducing gas oil into the water gas stream flowing through the carburetor and passing the resultant mixt. of oil gas and water gas through the superheater to fix the gas and to produce a carbureted water gas having a B. t. u. content approx. equal to that of natural gas, and mingling the gas thus produced with that produced in step (*b*).

Rotary-grate gas producers. Karl Koller. Brit. 508,584, July 4, 1939. These, having a rotatable ashpan provided with milling cutters and a submerged ring extending into the ashpan which carries a scraper member and a plurality of stemming shearing members, have the milling cutters arranged only at the periphery of the middle part of the ashpan bottom, which has the form of a steep surface of revolution, each cutter being provided with a vertical shield.

Apparatus suitable for the recovery of carbon dioxide from flue gases, etc., by use of an absorbing liquid. Gustave T. Reich. U. S. 2,183,943, Dec. 19. Various structural, mech. and operative details.

"Depoisoning" gases containing carbon monoxide. Franz Bössner and Carl Marischka. U. S. 2,183,301, Dec. 12. App. is described, and a continuous process for "depoisoning" gases contg. CO by converting the CO into a mixt. of CO_2 and H in the presence of steam and of ankerite, the latter being regenerated as soon as it becomes in-

active as regards the absorption of CO_2, by heating in a regeneration chamber and by being circulated between the gas-treating and regenerating chambers at a temp. of 400–800°.

Wood coke suitable for use in iron-ore reduction. Stevan Ruzicka. U. S. 2,184,317, Dec. 26. A wood coke is made consisting of a structure substantially entirely of cell walls corresponding to those of the wood from which the charcoal was made, formed of high-molecular C compds. and C and graphite, resulting from the conversion by cracking of constituents of the charcoal used in the making of the structure in a coking process, above temps. above the lowest-cracking temp. of the volatile constituents of the charcoal and at the highest temps. employed in the manuf. of artificial graphite.

Plug type coke-oven door. Louis Wilputte. U. S. 2,183,704, Dec. 19. Various structural details.

Operating end doors of horizontal coke-oven chambers. Joel S. Potter (to Louis Wilputte). U. S. 2,183,753, Dec. 19. Various details of app. and operation.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STEWART S. KURTZ, JR.

Posterity and petroleum. A. E. Dunstan. *Bull. assoc. franç. techniciens pétrole* No. 46, 235-43(1938). E. J. Mahler

Hydrogenation of Boldesti petroleum in relation to its chemical composition. C. Cândea and J. Kuhn. *Mon. pétrole roumain* **41**, 73-6(1940).—The aim of the work was to study the effect of hydrogenation upon different groups of hydrocarbons, either alone or mixed with Boldesti kerosene. Hydrogenation was conducted in a rotating autoclave at 450° and 1 atm. for 1 hr. The kerosene alone was hydrogenated with and without MoO_3. Less unsatd. hydrocarbons formed when the catalyst was used. A com. paraffin m. 51 56° hydrogenated at 420-450° in the presence of MoS_3 showed a remarkable change in yield of gasoline fractions with temp. rise, from 14% at 420 to 71% at 450°. The gasolines contained no unsatd. and very little aromatic hydrocarbons. Naphthenic acids from a Rumanian gas oil were easily converted to simple naphthenes in presence of MoO_3, CO_2 being found in the gaseous by-products. When 20% of C_5H_{10} was added to kerosene for treatment the product contained only 2% of unsatd. hydrocarbons. It appeared that under the conditions there had been no condensations, polymerizations or other more pronounced secondary reactions. In tests upon kerosene alone, (1) without initial pressure and (2) with 60 atm. initial N_2 pressure, the yields of gasoline were the same in both. E. E. Crandal

Refining of petroleum products by solvents. III. Selectivity of acetone at different temperatures. R. Verona and C. Fostiropol. *Bul. Chim. Soc. Române Chim.* **39**, 167–83(1937-38)(in French).—See *C. A.* **33**, 8411. A. D.

Utilization of petrolum gases. A. E. Dunstan. *Bull. assoc. franç. techniciens pétrole* No. 46, 191-9(1938). The uses of petroleum gases in the following processes are briefly outlined with charts: high-temp. pyrolysis, pyrolysis for production of aromatic gasoline, pyrolysis for production of olefin hydrocarbons, olefin polymerization and combined pyrolysis and polymerization. E. J. M.

Production of petroleum resins. S. C. Fulton and A. H. Gleason. *Ind. Eng. Chem.* **32**, 304-9(1940). Two general processes are outlined for the recovery of resins from cracking-coil tar. The first method consists in sepg. the resins by the aid of distn. and a selective solvent followed by acid treatment. In the second method the tar is distd. to a pitch of low m. p., which is treated with anhyd. $AlCl_3$ under condensing and polymerizing conditions without diln. The latter treatment, besides forming addnl. resins, causes the highly dispersed asphaltenes (defined as petr.-ether insol.) to coalesce, in which form they can be readily filtered from the oily hydrocarbons. Light petroleum distillates on solvent extn. yield highly aromatic concentrates which may be condensed with formaldehyde to form useful resins. This method of production is discussed from the viewpoint of feed stocks, catalysts (H_2SO_4, H_3PO_4, $ZnCl_2$), solvents for the reaction (AcOH, etc.), aldehydes used, and resin properties. With high-boiling distillates it is more difficult to obtain light-colored resins, regardless of whether cracked or virgin distillates are the starting materials. Heavy distillates, e. g., cracked oils, tars, and tar distillates, in addn. to formaldehyde condensation, may also be resinified by chlorination and thermal dehydrochlorination, or by chlorination and condensation with metallic halides. Charts are reproduced showing the formation of resins from 10° Am. Petroleum Inst. and 3° Am. Petroleum Inst cracking-coil tar, and from the light and heavy distillates. 27 references. Edward J. Mahler

Propane precipitation of petroleum resins. P. T. Graff and H. O. Forrest. *Ind. Eng. Chem.* **32**, 294-8 (1940).—Propane pptn. of petroleum resins is used commercially to reduce the duty of clay decolorizing lubricating oil stocks. Because of the high mol. wt. and high b. p. of these resins, it has been difficult to sep. them successfully from petroleum on an industrial scale. The pptn. is carried out at moderate temps., and therefore no injury results to the natural properties of the resin components of the crude oil. The essential operations of pptg. resins by liquid propane are indicated in a flow sheet showing the proportions of propane used, settling temps., and products realized from two-stage operations on mid-continent crude residuum. The first stage removes the asphalt, the second ppts. the resin material. Properties of the asphalt, resin and treated residua are given. Color bodies, C-forming material and asphaltenes are found in the depropanizing products. In addn., high-viscosity oil fractions settle out with the resin material, the oil consisting of naphthenes and paraffins of high mol. wt. The quantity and, to some extent, the nature of the oil so included may be controlled by the temp., and propane soln. ratio, and thus a means is available of making narrow cuts of high-viscosity products. One or more addnl. stages of settling in propane soln. will further subdivide the product into oils and a resinous residue. Process diagrams are also shown for deresining a Santa Fe Springs vacuum-still distillate, a Texas crude residuum, and a dewaxed Penn. cylinder stock. Treating data and properties of the products are also included. Edward J. Mahler

Polybutenes—properties and uses in petroleum products. R. M. Thomas, J. C. Zimmer, L. B. Turner, R. Rosen and P. K. Frolich. *Ind. Eng. Chem.* **32**, 299-304 (1940).—Polybutenes are prepd. commercially by low-temp. catalytic polymerization of isobutene contg. varying amts. of the butenes. The polymers vary in appearance from viscous, clear liquids to white, tough, elastic solids. The polybutenes are classified as polymers of low, medium, or high mol. wt., and are known commercially as Vistanex Polybutene LM, MM, and HM accordingly. The various grades of the polymers can be classified according to their apparent mol. wt. as detd. by the Staudinger method (*Der. Aufbau der hochmolekularen org. Verbindungen*, *C. A.* **26**, 3513) based on the change on viscosity of a solvent to which mols. of a threadlike nature have been added. Higher polymers dissolved in heptane suffer mol. breakdown when subjected to violent shaking. A table is given showing the mol. wts. of polybutenes as detd. by the Staudinger method and by the cryoscopic method. The general properties of these substances and their use in various petroleum products, such as lubricating oils, greases, asphalt and wax, are described. At ordinary temps. the polymers are chemically inert and stable. They dissolve in liquid aliphatic hydrocarbons and in certain chlorinated hydrocarbons. A concentrate of the polymers of low mol. wt. dissolved in a light and well-

refined lubricating oil when added to mineral oils improves their viscosity index characteristics. The higher polymers, owing to their rubber-like properties, produce highly viscous solns. having a stringy consistency. They are used to impart string to grease and special oils, in which rubber was formerly employed. The effect of polybutenes on the phys. properties of asphalts of varying softening points is shown in a table contg. characteristics of such blends. Viscosity, low-temp. flexibility, sealing strength, etc., of waxes are improved by the addn. of polybutenes. E. J. Mahler

The fractionation of Turner Valley (Canada) crude oils using Stedman columns. R. M. Donald. *Can. J. Research* **18, B,** 12–29(1940).—A Sterling Pacific no. 3 crude oil (33.2 I.), Royalite Oil Co., Alberta, Canada, was sepd. into 6 fractions in a Stedman gauze-packed column (cf. *C. A.* **31,** 8259[5]) 2 ft. long and 3 in. in diam. These cuts were then carefully fractionated in a 5-ft. Stedman column 3 in. in diam. The compn. of the fractions thereby obtained, based on the b.-p. curve and on the *n* of the fractions, after removal of the aromatic constituents by carefully controlled nitration (Bruun, Leslie and Schicktanz, *C. A.* **25,** 2551) gave the following vol. percentage compns. of the crude oil boiling below 81° (the second figure represents the percentage of this constituent in a mid-continent crude oil investigated at the U. S. National Bureau of Standards (cf. Bruun and Hicks-Bruun, *C. A.* 25, 2551)): isopentane 0.38, —; pentane 0.79, —; cyclopentane 0.09, —; 2,2-dimethylbutane 0.11, —; 2,3-dimethylbutane 0.27, 0.04; 2-methylpentane 0.94, 0.09; 3-methylpentane 0.56, 0.18; hexane 2.40, 0.33; methylcyclopentane 0.82, 0.20; benzene 0.32, 0.08; cyclohexane 0.76, 0.33. The compn. of the fractions boiling above 80° has not been detd. with the same accuracy as was possible with the lower-boiling constituents, but the following is a preliminary estimate of the higher-boiling constituents in the crude oil (the second figure represents the percentage of this constituent reported in a mid-continent crude oil): dimethylcyclopentane 0.75, 0.4; 2-methylhexane 1.0, 0.3; 3-methylhexane 0.7, 0.2; heptane 1.6, 0.9; methylcyclohexane and ethylcyclohexane 0.6, 0.1; three xylenes and ethylbenzene 2.5, 3.1; nonane 0.8, 1.0; trimethylbenzenes 1.6, 0.28. The higher-boiling constituents could not be estd. with the data at hand, but the presence of decane, hendecane, the diethylbenzenes, butylbenzene, tetramethylbenzenes and *n*-, *sec*-, and *tert*-butylcyclohexanes was indicated in the fractions boiling from 174 to 200°. Ultraviolet absorption studies made on the higher-boiling fractions failed to identify completely the aromatic compds. in this range. W. Gordon Rose

Selective refining of some Rumanian mineral oils by means of nitrobenzene and phenol. I. L. Blum and N. Popescu. *Bul. Chim. Soc. Române Chim.* **39,** 153–4 (1937–38)(in German). See *C. A.* **33,** 841[6]. A. D.

Catalytic alkylation of isobutane with gaseous olefins. F. H. Blunck and D. R. Carmody. *Ind. Eng. Chem.* **32,** 328–30(1940).—At 1000 lb./sq. in. and about 400°F., isobutane reacts with gaseous olefins under the influence of double chlorides of Al and alkali metals, particularly $NaCl.AlCl_3$ and $LiCl.AlCl_3$. The alkylation reaction must compete with the polymerization reaction under these conditions, so the olefin concn. should be kept low. It would be advantageous to bleed in the olefin gradually to the paraffin, either in a static or a flow system; this was not followed in the expts. herein described. The mixt. of olefin and excess paraffin was simply passed over the catalyst. The catalyst was prepd. by heating the alkali chloride and anhyd. $AlCl_3$ to 500°F. in a sealed glass tube placed inside a sealed steel bomb, remelting the complex salt to sublime off any unchanged $AlCl_3$, and pouring the molten double salt onto an equal wt. of pumice carrier. $NH_4Cl.AlCl_3$ is somewhat less reactive than the above salts and the KCl complex is almost inactive. The alkylation reaction is accompanied by a varying but considerable amt. of polymerization in all cases, and by extensive rearrangements, which lead to the production of products with all possible nos. of C atoms in the gasoline range. The life of the catalyst is short, and the alkylation reaction declines more rapidly than the polymerization. The optimum temp. for the production of liquid hydrocarbon products is around 440°F. When the feed vol./catalyst vol./hr. exceeds 4.0 the yield falls off rapidly. Tabular results are given for the alkylation of isobutane with propylene over $LiCl.AlCl_3$, and for the alkylation of isobutane with isobutylene, propylene and ethylene over $NaCl.AlCl_3$. Edward J. Mahler

Production of high-octane gasoline in American refineries. E. Vellinger. *Bull. assoc. franç. techniciens pétrole* No. **47,** 61–85(1939).—As a member of the French official committee sent to America to study the methods of manuf. of high-octane-no. gasoline, V. reports on the following refinery operations: the Dominguez polymerization unit of Shell for the transformation of butylene to isooctane; the U. O. P. catalytic polymerization plant in which solid H_3PO_4 on a porcelain carrier is employed for the polymerization of olefins, at 175° and 40 kg. pressure; the low-pressure hydrogenation unit at Dominguez, Calif., operating at 180° and 4 kg. using a $NiNO_3$-porcelain catalyst; the high-pressure hydrogenation unit of the S. O. Co. of La. at Baton Rouge; the Shell Chem. Co. alc. and chem. plant at Dominguez; and the Socony-Vacuum plants at Marcus Hook and Paulsboro employing the Houdry cracking process. The results of the Bureau of Standards on fractionation of crude oil are commented on. Five flow diagrams are given. E. J. Mahler

Cracked gasoline as aviation fuel. E. Vellinger and G. Radulesco. *IIme Congr. mondial pétrole* **3,** Sect. 4, 820–1 (1937)(in French).—Cracked gasoline can be used as an aviation motor fuel provided proper antioxidants are incorporated therein. Certain antioxidants are active at high temps. and their period of stabilizing activity is long enough to prevent gum formation during the passage of gasoline vapors from the tank through the lines to the carburetor. Antioxidants are also useful in stored cracked gasolines and the activity may be periodically checked by means of a special app. for recording stability changes due to O absorption. E. J. Mahler

Manufacture of synthetic gasoline in Germany. A visit to the Leuna works. Michel N. Constantinescu. *Mon. pétrole roumain* **41,** 133–8(1940).—The works at Leuna producing NH_3, MeOH, gasoline and oils use air, water and lignite as raw materials. The site of the works was chosen close to lignite deposits of probably a billion and a quarter tons; and 25,000 tons of lignite is mined daily. Winkler gas producers burning lignite and coke make the CO and H_2. By liquefying the air the N_2 is sepd. from the O_2. The H_2 for the NH_3 synthesis is completely freed of the oxides of C. The lignite must have its water content reduced to 4% before it, with the catalyst, is made into a paste with a heavy oil and subjected to the action of H_2 under 200 atm. pressure. Operation is conducted first in liquid phase and then in vapor phase. Up to 97% of the lignite is converted to gasoline, gas and oil. The gasoline differs in no respect from that made from petroleum. Emma E. Crandal

Influence of antidetonation admixtures on the octane number of shale gasoline. N. V. Ershov. *J. Applied Chem.* (U. S. S. R.) **12,** 871–3 (in French, 874)(1939).—The effects of EtOH, aniline and tetraethyl lead and their mixts., on the octane no. of shale gasoline (cf. *C. A.* **34,** 611[9]) were investigated and data are plotted. Each 10% addn. of EtOH increased the octane no. approx. by 3 points, each 1% of aniline increased it by 1–3 points and 2 cc. per 1 kg. of gasoline increased the octane no. by 6 points and 3 cc. by 9 points. The greatest effect in increasing the octane no. was obtained by adding alc.-tetraethyl lead or alc.-aniline mixt. An addn. of the tetraethyl lead-aniline mixt. caused pptn. and decreased the octane no. A. A. Podgorny

New blending agents for aviation gasoline of 100 octane number. E. Hofman, M. Lapeyrouse and W. Sweeney. *IIme Congr. mondial pétrole* **3,** Sect. 4, 812–19(1937)(in English).—Recent developments in aviation gasoline addn. agents are reviewed. The properties of iso-Pr_2O as a blending agent are discussed together with actual engine tests and successful storage stability tests on fuels

contg. it. Octane blending values of mixed ethers are also tabulated. E. J. Mahler

Correlation of octane numbers with road performance. C. B. Kuss, A. J. Blackwood and G. H. B. Davis. *IIme Congr. mondial pétrole* **3**, Sect. 4, 780–9(1937)(in English).—A dual system of octane rating is proposed for gasolines, one for high-atm.-temp. performance and the other for low-temp. performance. This is necessary because the C. F. R. Motor Method, while adequate for high-atm.-temp. ratings (100–110°F.), shows a poor degree of correlation at lower temps., reaching a min. at about 40°F. Correlation test results from runs at San Bernardino, Tulsa and Detroit are reported in graphs. In these tests the av. road rating was 3.05 octane no. higher than the av. C. F. R. Motor Method values. Road ratings made at 30–50°F. correlate well with the Research Method values and the degree of correlation becomes poorer for higher temps., the av. road rating being 2.92 octane no. lower than the av. Research rating in the Tulsa tests at 100°F. On the basis of a dual rating system for high and low temps. an octane no. index for gasolines corresponding to the detn. of 2 viscosities of an oil at 2 temps. for viscosity index calcn. could be developed serving a similar purpose. E. J. Mahler

Laws regulating the oxidation of fuel mixtures in combustion motors and the possible connection with knock. M. Prettre. *IIme Congr. mondial pétrole* **3**, Sect. 4, 732–7(1937)(in French).—A close relationship exists between the spontaneous oxidation of fuel mixts. and the tendency to knock. P. contends that a quant. study of the oxidation together with a kinetic study of the process should reveal all the factors entering into the phenomenon of knock, and permit the detn. of the law governing the oxidation reaction, combustion and flame ignition. The accelerating effect of chemically inert gases, e. g., N_2 and A, on combustion and the interference of the walls of the combustion chamber should be taken into account when knock tendency is measured. 21 references. E. J. Mahler

Classification of gasolines based on knock tendency. Max Serruys. *IIme Congr. mondial pétrole* **3**, Sect. 4, 721–6(1937)(in French).—Gasolines can be classified according to their knock tendency by a known detn. and the "synthetic index," which represents the power output ratio of a certain fuel to the reference fuel. This index serves at the same time as a key to the "knock index" and the "consumption index." Knock index represents supercharging and supercompression possibilities compared with the reference fuel, and the "consumption index" is indicative of the consumption rate under the above circumstances. Practically the "synthetic index" furnishes a simple method for obtaining for each fuel representative figures for specific consumption power and rate of feed. The index value may replace to a certain extent the pressure limit of detonation in theoretical studies. E. J. Mahler

Knock ratings of gasolines and their chemical composition. E. B. Evans and F. H. Garner. *IIme Congr. mondial pétrole* **3**, Sect. 4, 753–9(1937)(in English).—A no. of gasolines of which 50% distils at 100° were prepd. from crude oils of various sources, and their phys. properties, hydrocarbon contents and octane nos. at 212°F. and 300°F. jacket temp. on the S-30 engine were detd. both before and after removal of aromatic constituents. The octane blending values of aromatic hydrocarbons and naphthenes are 115 and 51 at 212° and 106 and 45, resp., at 300°F. No similar value can be ascertained for paraffins because the normal and isoparaffins differ greatly in octane no. and cannot be differentiated by chem. analysis. If the aniline points and the octane nos of the various hydrocarbons and of the nonaromatic gasolines are plotted, the engine results indicate very clearly the approx. compns. of the nonaromatic gasolines in terms of the normal and isoparaffins and naphthenes. Thus, it is shown that Mexican and Persian gasolines contain considerable amts. of straight-chain paraffins; Miri gasoline is highly naphthenic and California gasoline, usually considered naphthenic, contains large amts. of isoparaffins. Other properties, such as d_4 and n of the aromatic residue, support these conclusions. E. J. Mahler

Supercharged knock testing. S. D. Heron and F. Gillig. *IIme Congr. mondial pétrole* **3**, Sect. 4, 769–79(1937)(in English).—Representative motor fuels were studied in a supercharged C. F. R. engine with systematically varied engine conditions to det. the sensitivity of knock measurements to supercharging. Com. isoöctane and a low-octane Michigan straight-run gasoline were employed as reference fuels. Blends of the 2 fuels were used for ratings below 100 octane no. and isoöctane plus $PbEt_4$ for antiknock values above 100. The permissible indicated mean effective pressure for the reference fuel blends increases sharply with increase of engine speed, while for benzene, toluene, methanol and its blends, and diisobutylene it decreases with increase in engine speed. This results in a pronounced effect of engine speed on the relative ratings of aromatic compds., aromatic blends, methanol, etc., in terms of the reference fuels. Increase of jacket temp. decreases the permissible boost and the indicated mean effective pressure for both the test and the reference fuels, the former being more sharply reduced. Engine speed and jacket temp. have only a slight effect on the relative ratings of diisopropyl ether and isooctane-isopentane blends. The sensitivity of detn. of octane no. increments in the range from 100 octane no. to isoöctane plus 3 cc. $PbEt_4$/gal. is much greater with supercharging than with existing test methods. The effect of high jacket temp. on increase of the charge temp. is almost directly proportional to the duration of the intake period. Supercharging in conjunction with changes in engine speed and cylinder temp. gives rise to large variations of the relative ratings of the pregnitum group of fuels in terms of the reference fuels. Latent heat of evapn. has but little effect on vol. efficiency (indicated mean effective pressure). Because of the insufficient range of present reference fuels the supercharged engine will have to be resorted to for octane measurements. E. J. Mahler

Effect of fuel richness on detonation. L. A. Peletier. *IIme Congr. mondial pétrole* **3**, Sect. 4, 744–52(1937)(in French).—Curves are given for a C. F. R. engine and for an air-cooled aircraft test engine expressing the effect of mixt. strength in terms of the allowable power output at incipient detonation. The effect of mixt. strength on the ratio of sp. heats, mixt. temp., flame speed, and on combustion wall temp. has been considered and an attempt has been made to gage the effect of these factors on knock tendency. From tests on the C. F. R. engine in which mixts. were compressed without spark until ignition occurred (to imitate the conditions of the end gas) it might be concluded that the tendency to self-ignite is a max. at a very rich mixt. ratio (about 70%). The tendency to detonate is a max. at a much leaner mixt. strength (about 5–10%). From this it may be concluded that the mixt. strength, by influencing the conditions to which the end gas is subjected, has an indirect effect on the self-ignition of this end gas, which appears to predominate over the direct effect of mixt. strength on the self-ignition tendency of the end gas as such. E. J. Mahler

Stationary gas waves in the detonation zone of gasoline motors. J. J. Broeze, H. van Driel and L. A. Peletier. *IIme Congr. mondial pétrole* **3**, Sect. 4, 727–31(1937)(in French).—Recordings were made of the combustion taking place within the cylinder head and the features accompanying it, such as pressure changes, heat evolution, vibrations and luminosity. Av. wall temp. was observed by means of temp. plugs. When detonation occurred a stationary gas wave could be observed accompanied by pressure vibrations caused by more rapid combustion of the end gas. Three different zones can be distinguished: the detonation zone, where the end gas burns rapidly; the zone of greatest pressure and vibration; and the zone in which the greatest amt. of heat is transmitted to the cylinder walls. E. J. Mahler

Detection [and determination] of lead tetraethyl in fuels. K. E. Schulze. *Chem.-Ztg.* **64**, 47(1940).—To 1–2 cg. $KClO_3$ in a test tube add about 5 cc. of gasoline to be tested, then 3–5 drops of HCl (d. 1.19). Cl formed

converts the $PbEt_4$ to $PbCl_2$, recognized by the turbidity produced in the gasoline. The method is sensitive to 1 part in 5000. After a time the $PbCl_2$ settles out of the gasoline and is redissolved in the KCl soln. formed. The method can be made quant. by pouring off the clear gasoline, neutralizing the aq. soln. with NaOH, adding $Na_2S_2O_3$, and pptg. PbS by means of H_2S. E. H. 1

The purification and separation of hydrocarbons. A. Foulon. *Teer u. Bitumen* **37**, 325–7(1939).—A brief description of several patented processes for the refining of hydrocarbons. F. W. Jung 2

Raman effect of hydrocarbons and the analysis of liquid fuels. M. V. Vol'kenshtein. *Uspekhi Khim.* **8**, 970–97 (1939).—Data are given on the Raman spectra of numerous hydrocarbons and the qual. and approx. quant. analysis of motor fuels by means of their Raman spectra are discussed for various fractions. A complete analysis is possible in solns. F. H. Rathmann 3

Polymerization of unsaturated hydrocarbons. H. I. Waterman. *Bull. assoc. franç. techniciens pétrole* No. **46**, 183–9(1938); cf. *C. A.* **32**, 4318³.—The production of hydrocarbon mixts. by polymerization of unsatd. compds. has led to methods of detg. the compn. of the resulting products. The properties of the products can be ascertained by studying the structure of the compds. contained therein. The methods advanced by W., Vlugter and van Westen, using sp. refraction and the sp. parachor, are reviewed. E. J. Mahler 4

Construction of large reservoirs for hydrocarbons. Ch. Berthelot. *Génie civil* **115**, 301–5, 322–3(1939).—The advantages of the various types of reservoirs (metallic and concrete) for storing hydrocarbons are discussed. Losses by evapn. are compared, also costs. A. N. H.

Isomorphism of paraffins. Mathieu. *Bull. assoc. franç. techniciens pétrole* No. **46**, 71–91(1938).—The relationship existing between mol. structure and chem. properties of paraffinic substances is considered an important basis for the detn. of the properties of paraffinic oil mixts. that are difficult to analyze when the components are of diverse origin. The work of Piper, Francis and Chibnall, etc., is reviewed, and it is concluded that the dissymmetry of the mols. is responsible for the properties of paraffin hydrocarbons, such as viscosity, wetting power, soly. and solvent power. Numerous graphs and diagrams are given. E. J. Mahler 5

Paraffin wax, ozocerite and ceresin—the Russian standards reviewed and criticized. I. Leo Ivanoszky. *Oil Colour Trades J.* **97**, 241, 243(1940).—The Russian standards for the wax-like solid hydrocarbons have much more the character of standards for trade in the material than of standards for their testing and evaluation. The Russian standards are given for these types of waxes. **II. Testing methods.** *Ibid.* 297–9.—Color, solidifying and drop point, penetration, sp. gr., mech. impurities, water estn., test for soly. and for absence of water and of mech. impurities, mineral acids or alkali, org. acids, saponifiable matter, flash point and ceresin content are considered. W. H. Boynton 6

New solvent dewaxing processes. P. M. Edmond Schmitz. *Bull. assoc. franç. techniciens pétrole* No. **47**, 39–59(1939).—Dewaxing processes employed since 1835 are reviewed. Diagrams are given showing the dewaxing processes employing all the known solvents. Special attention is given to propane deasphalting and deresining. Properties of a suitable solvent for the dewaxing process are outlined. 47 references. E. J. Mahler 7

Synthesis of lubricating oils. G. Hugel. *Bull. assoc. franç. techniciens pétrole* No. **46**, 57–60(1938); cf. *C. A.* **33**, 7542¹.—Besides viscosity there are other properties of synthetic lubricants that must approach those of the natural product, e. g., thermal stability, age resistance and oiliness. The reason for the poor viscosity curve of naphthenic oils is the phenomenon of mol. assocn. brought about largely by temp. If it were possible to ascertain the nature of the mol. aggregation it would be possible to modify it by changing the structure of the mols. When the problem of the viscosity index of cyclic oils is cleared up the synthesis of lubricants will be greatly advanced. E. J. M. 8

Bearing corrosion and Diesel-engine lubrication. C. J. Copley. *Southern Power and Ind.* **58**, No. 2, 58–62(1940).—Modern Diesel engines operate at higher speeds, higher temps. and higher compression ratios than in the past and as a result new bearing metals have been required. The new operating conditions tend to cause more rapid oxidation of the lubricating oil, with acid formation, and corrosion of the bearings. This has been eliminated by the use of addn. agents to the oil. Other desired characteristics of the Diesel-engine lubricating oil are also secured by compounding. A straight mineral oil is unsuited for lubricating such engines. R. W. Ryan 9

A new simple method of recovery of used lubricating oil. Syozi Hamagami. *J. Fuel Soc. Japan* **18**, 995–1000(English abstr. a83–4)(1939).—The sample (1 kg.: 0.14% of ash, 17% of petr. ether-insol. residue and 15% of residue separable by a centrifuge) was warmed to 80° and 200 cc. of 1% NaOH was added. The mixt. was stirred quietly for 10 min.; the color on the surface changed from black to transparent brown. The liquid was then allowed to stand for about 20 min. and the clarified oil was extd. by a siphon. The yield of the recovered oil was about 75%. The recovered oil was transparent reddish brown and contained practically no mineral matter; flash point 178°; viscosity (Redwood) 1030 and 297 at 30 and 25°, resp. F. I. Nakamura 10

Stability of crankcase oils. W. F. Weiland. *Trans. Am. Soc. Mech. Engrs.* **62**, 125–32(1940).—W. attempts to answer 2 questions concerning lubricating oils: (1) performance and (2) useful life. Oxidation and corrosion tendencies constitute the major elements in the deterioration of crankcase oils. W. outlines the requirements for conducting oxidation tests and also includes the results of tests. Behavior of oils in service offers a means of predicting oil performance. Acid-vapor tests to det. oil breakdown are discussed and the results of corrosion studies are detailed. Saverio Zuffanti 11

A primer in oils. Harry D. Kolb. *Blast Furnace Steel Plant* **27**, 587–91(1939).—Characteristics and properties of lubricating oils are discussed. C. B. Jenni 12

Rheological properties of asphaltic bitumens. R. N. J. Saal and J. W. A. Labout. *J. Phys. Chem.* **44**, 149–65(1940).—After an extensive study of the rheological properties of 2 quite different bitumens made by measuring the deformation under const. shearing stress, the elastic recovery and different combinations of these by means of a conicylindrical viscometer, S. and L. conclude that asphaltic bitumens must be considered mixed gel-sol systems and that the degrees of structure exhibited can vary widely with compn. These conclusions were reached previously by Pfeiffer and van Doormaal (*C. A.* **30**, 6545⁷). 6 references. Henri Marc 13

Asphaltic bitumen as colloid system. J. Ph. Pfeiffer and R. N. J. Saal. *J. Phys. Chem.* **44**, 139–49(1940).—P. and S. found little difference between the C/H ratios of the asphaltenes of most steam-refined and blown products examd.; they varied in most cases from 0.8 to 0.9. The asphaltenes from cracked residues showed ratios up to about 1.3. By studying the rheological properties of synthetic bitumens prepd. in the lab. with a conicylindrical rotation viscometer P. and S. also found that the tendency of asphaltic bitumens to form gel structures is absent in the presence of a certain excess of aromatic malthenes and increases as the aromatic content of the malthenes is lowered. By a "sweating" process not described in detail P. and S. studied 3 asphalts of the same penetration index but differing in asphaltene content and were able to sep. the intermicellar liquid from the micelles and intramicellar liquid and to show that this "sweated" oil is practically free from asphaltenes. They concluded that at normal temp. the micelles in asphaltic bitumen consist of asphaltenes to which a substantial portion of the malthenes may be bound and that since the quant. ratio between the vol. of the micelles and that of the asphaltenes is not const., the quantity of asphaltenes is to be considered only as a very approx. indication of the micelle content. 6 references. Henri Marc 14

The destructive distillation of coconut shells. Reginald

Child. *Trop. Agr.* (Ceylon) **93**, 195–204(1939).—About 40,000 tons of coconut shells is burned annually in Ceylon to produce about 13,600 tons of charcoal, without attempts to recover by-products. The destructive distn. of coconut shells yields charcoal 34, pyroligneous acid 40, tar 6 and gas 20%. The economics connected with the distn. process and the production of chemicals from the by-products are discussed. Thirteen references. J. O. H.

Breaking emulsions such as natural petroleum oil and brine emulsions. Ivor M. Colbeth (to Baker Castor Oil Co.). U. S. 2,183,487, Dec. 12. Emulsified liquids have mixed with them castor oil, that has been bleached by oxidation at a temp. of about 160° and then oxidized by blowing air through it at a temp. of about 140°, the oxidation continuing until compds. are obtained including both aldehydes and acids, and the bleached and oxidized oil is modified by treating it with an aldehyde reactive reagent such as $NaHSO_3$, NH_3 or an aromatic amine, etc.

Agitating and mixing apparatus suitable for mixing petroleum oil with refining reagents, etc. Warren O. Chace. U. S. 2,183,859, Dec. 19. Various structural and operative details.

Heat-exchange apparatus suitable for use in petroleum-oil refining. Charles H. Leach. U. S. 2,181,308, Dec. 26. Various structural details.

Conversion of hydrocarbon oil. Charles H. Angell (to Universal Oil Products Co.). U. S. 2,184,069, Dec. 19. An arrangement of app. is described, and a process which involves distg. an oil such as a crude petroleum contg. poor antiknock gasoline and essentially paraffinic gases to recover a gasolinic distillate and lighter fractions comprising at least a major portion of the paraffinic gases, subjecting the distillate to conversion conditions regulated to effect the production therefrom of high yields of good antiknock gasoline and substantial quantities of readily polymerizable, normally gaseous olefins, recovering the good antiknock gasoline from the resulting conversion products in the form of a distillate substantially free of dissolved normally gaseous olefins, adding to the last named distillate substantial quantities of the heavy paraffinic gases resulting from the distillation step to form a gasoline product of materially increased vapor pressure, and separately recovering from the conversion products a mixt. of normally gaseous hydrocarbons contg. a high concn. of readily polymerizable olefins.

Treatment of hydrocarbon oils and gases. Clarence G. Gerhold (to Universal Oil Products Co.). U. S. 2,184,096, Dec. 19. An arrangement of app. is described, and a process of obtaining polymerizer charging stock from the sepd. pressure distillate of substantially gasoline boiling range and normally incondensable gases produced in the cracking of hydrocarbon oil, which comprises stabilizing the distillate of substantially gasoline-boiling range to liberate dissolved normally gaseous hydrocarbons therefrom, sepg. the stabilized distillate into relatively light and heavy fractions, scrubbing the incondensable gases with at least a portion of the heavy fraction to absorb in the latter heavier polymerizable components of the gases and to sep. these components from lighter unpolymerizable components of the gases, isolating the unabsorbed gases from the process, supplying the enriched portion of the heavy fraction to the stabilizing step to free the same of the absorbed heavier components of the gases and to combine these components with the normally gaseous hydrocarbons liberated from the distillate, and recovering, as the polymerizer stock, independently of the unabsorbed gases, the overhead product of the stabilization.

Extraction and separation of hydrocarbon mixtures by use of solvents. James H. Boyd, Jr. (to E. I. du Pont de Nemours & Co.). U. S. 2,183,852, Dec. 19. Normally liquid hydrocarbon mixts. are treated, as for effecting fractional sepn. of paraffin and naphthene constituents from mixts. such as petroleum oils, by use of a solvent contg. dimethylformamide or other substituted aliphatic amide of an acid of from 1 to 4 C atoms together with MeOH or other compd. of the general formula ROH in which R represents H or an alkyl or a methylol group.

Removing acid components from hydrocarbon distillates. David L. Yabroff (to Shell Development Co.). U. S. 2,183,801, Dec. 19. A process of sepg. org. acid-reacting substances contained in a water-insol. neutral or basic liquid such as a west-Texas straight-run gasoline, involves treating the liquid with an aq. soln. of a strong base such as NaOH contg. a substantial amt. of dissolved propylene glycol and contg. 15 70% of water, under conditions (suitably at 0 60°) to absorb at least a portion of the acid-reacting substances in the aq. soln. and to form 2 liquid layers, one comprising the aq. soln. contg. absorbed acid-reacting substances and the other consisting essentially of the treated org. liquid, and the layers are sepd. Cf. *C. A.* **33**, 4011².

Recovering mercaptans from hydrocarbon distillates. Thomas F. McCormick and Arthur Lazar (to Tide Water Associated Oil Co.). U. S. 2,183,968, Dec. 19. A process of recovering mercaptans from hydrocarbon distillates comprises treating a hydrocarbon distillate contg. mercaptans, H_2S, and other acidic compds. with a NaOH soln. at a temp. between the freezing point of the soln. and 150° sufficiently high to remove selectively substantially all the acidic compds. of a greater acidity than the mercaptans so that the mercaptans remain dissolved in the distillate, treating the distillate with further NaOH soln. while at a lower temp. between the freezing point of the soln. and about 15° sufficiently low for the soln. to absorb the greater portion of the mercaptans, then freeing the mercaptans from the soln.

Decolorizing oils. Ernest W. Rembert (to Johns Manville Corp.). U. S. 2,183,590, Dec. 19. A method of decolorizing an oil such as Penna. petroleum oil, comprises mixing therewith a hydrous, pptd., absorbent Mg silicate, heating the mixt., and sepg. the silicate and adsorbed decolorizing constituents from the oil; the moisture content of the silicate is adjusted to a quantity predetd. in accordance with the temp. to which the mixt. is treated, the moisture content is adjusted to a min. of 18% by wt. of the silicate for treatments at temps. in excess of 205°, and to a content of 12–18% for treatments at 105 205°, and 6 12% for treatments at temps. of 38–105°.

Device for removing paraffin from well tubing. John C. Lucceus (to Herbert C. Otis). U. S. 2,184,393, Dec. 26. Various details of a device with scraping blades.

Locating water leakages into oil wells. Geo. H. Enns (50% to Robert V. Funk). U. S. 2,184,338, Dec. 26. App. is described, and a method of operation which involves testing the electrochem. qualities of the residual material in the well at different levels in the well without the addn. of any substance to the material in the well, causing an ingress of connate fluid into the well, and again testing the electrochem. qualities of the material in the well at different levels to determine the point of entrance of the connate fluid.

Recovery of solvents from crude paraffin. Texaco Development Corp. (Herbert L. Duffy, inventor). Ger.

684,966, Dec. 9, 1939 (Cl. 23*b*. 2.01). Crude paraffin is sepd. by treatment of a mineral oil with a solvent mixt. contg. a water-sol. or water-miscible component, (e. g., acetone) and cooling. The paraffin is heated to a temp. (e. g., 31°) at which it dissolves in the solvent contained therein. This soln. is let stand at this temp. until an aq. layer seps. The solvent is recovered from the aq. layer by distn.

Desulfurizing light petroleum distillates such as gasoline and kerosene. Ulric B. Bray (to Union Oil Co. of Calif.). U. S. 2,183,782, Dec. 19. Vapors of a distillate contg. objectionable org. S compds. are brought into contact with a porous oxide of Zn at a temp. (suitably about 205–340°) to cause some of the oxide to react with the org. S compds. to produce a catalytic metal sulfide, and the contact is continued at temps. of about 200–330° to convert the org. S compds. into org. sulfides, and the distillate is sepd. from the metal oxides and sulfides. 2

Stabilizing gasoline. Paul D. Barton, Karl Finsterbusch and Nathaniel M. Floyd (to American Locomotive Co.). U. S. 2,183,604, Dec. 19. An arrangement of app. is described, and a process wherein a hydrocarbon mixt. including gasoline-like hydrocarbons is fractionated in a first fractionating zone to sep. the heavier from the lighter hydrocarbons of the mixt., and wherein certain of the lighter hydrocarbons are then fractionated in a higher-pressure fractionating zone to recover a stabilized light motor fuel. The process comprises removing such a portion of the lighter hydrocarbons from the mixt. before the first fractionating step is performed that hydrocarbons uncondensed by the first fractionating operation are substantially completely condensable under a pressure no higher than exists in the first fractionating zone and at normal atm. temp., then performing the first fractionating operation on the balance only of the mixt. and, subjecting the initially removed portion of lighter hydrocarbons to fractionation in the higher-pressure fractionating zone with the lighter hydrocarbons from the first fractionating zone. 3 4 5

Increasing the octane number of gasoline stock. Walter A. Schulze (to Phillips Petroleum Co.). U. S. 2,183,591, Dec. 19. An arrangement of app. is described, and a process of treating a gasoline stock to increase its octane number, which comprises bringing the gasoline stock in the vapor form at pressures in the range of atmospheric to 100 lb. per sq. in. into contact with a bauxite catalyst impregnated with a soln. of a Cr compd. subsequently converted to the oxide; the catalyst contg. a major proportion of bauxite and a minor proportion of Cr oxide, at a temp. of 425–600° and a flow rate of about 1 to 10 liquid vols. of gasoline stock per hr. per vol. of catalyst. The decomposed impurities and the light gas fraction contg. a substantial proportion of H are sepd. from the hydrocarbons boiling within the gasoline range, and a gasoline stock with a higher octane number than the untreated gasoline stock boiling within the same temp. range is obtained. 6

Purifying raw gasoline distillates. Rudolph C. Osterstrom (to Pure Oil Co.). U. S. reissue 21,299, Dec. 12. A reissue of original patent No. 1,891,109 (*C. A.* **27**, 2026).

Filter suitable for use with gasoline as fed to engines. Alfred C. Korte (to Carter Carburetor Corp.). U. S. 2,183,616, Dec. 19. Various structural details. 7

Diesel-engine fuel oils. Bernard H. Shoemaker and Howard R. Batchelder (to Standard Oil Co.). U. S. 2,184,440, Dec. 26. A method of obtaining Diesel-engine fuel oils having good ignition characteristics and substantially free from corrosive S involves treating a stove distillate obtained from a crude oil of the Winkler type with Na plumbite in the presence of S amounting to about 7 times the theoretical amt. of S required normally to sweeten such a distillate, distg. the treated stove distillate to produce an overhead amounting to about 30% of the original stock and a bottom stock amounting to about 70% of the original stock, further reducing the bottom stock by suitable means to produce a reduced bottoms amounting to about 1% to about 6% of the original stove distillate and adding 0.5–5% of the reduced bottoms to distillate fuel oils having undesirable ignition characteristics. 8

Lubricating oil. Ulric B. Bray (to Union Oil Co. of Calif.). U. S. 2,183,783, Dec. 19. A lubricating oil of low pour point is prepd. contg. a large proportion of a highly refined mineral spray oil having a high de Ong no. and low viscosity and a highly refined paraffinic viscous lubricating-oil fraction of relatively greater viscosity.

Lubricating oils. N. V. de Bataafsche Petroleum Maatschappij. Dutch 47,379, Dec. 15, 1939. Aviation lubricating oils are prepd. by mixing natural lubricating oils made by ordinary refining methods with synthetic lubricating oils made by polymerization of alkenes, which may contain aromatic compds., at 20° by means of $AlCl_3$. The former oil has a viscosity index above +80 and a viscosity of more than 10° Engler at 50°; the synthetic oil has a viscosity between 25° and 75° Engler at 50°. The synthetic oil contains substances of high film-forming temp. little tendency to carbonize, etc. The mixt. of natural oil with synthetic bright stock has higher Conradson carbon no. and oxidation test than has a mixt. of natural oil with natural bright stock.

Mineral lubricating oil. Standard Oil Development Co. Ger. 684,967, Dec. 8, 1939 (Cl. 23*c*. 1). The oil, of a viscosity index above 60, which has been subjected to a suitable mild oxidation, contains dissolved Pb soaps and corrosive S combined with mineral, plant or animal oil in an amt. calcd. not to exceed the stoichiometric ratio of Pb:S but at least equal to 0.2%.

Lubricating oil composition suitable for use under extreme pressures. Bert H. Lincoln and Alfred Henriksen (to Lubri-Zol Development Corp.). U. S. 2,183,294, Dec. 12. A mineral lubricating oil is used with about 0.1–20% of a halogenated oxidation product of a hydrocarbon oil in which alcs. and acids present have been esterified.

Filter for engine lubricating oil or other liquids or gases. Paul Belyavin (to Flexofiltration Ltd.). U. S. 2,184,243, Dec. 19. Various structural details.

Lubricant. Standard Oil Development Company. Ger. 684,821, Dec. 6, 1939 (Cl. 23*c*. 1). The lubricant contains as an added material some 0.25–5.5% of an ester, b. 150°, acid of an aliphatic monocarboxylic acid contg. at least 6 C atoms with a monohydric aliphatic alc. contg. not more than 5 C atoms.

Lubricants. N. V. de Bataafsche Petroleum Maatschappij (F. R. Moser and J. M. Hoeffelman, inventors). Dutch 47,234, Dec. 15, 1939. Lubricants are improved by addn. of ternary sulfonium compds. of the general formula RR′R″SX, in which R, R′ and R″ are aliphatic cyclic or alicyclic groups. Preferably one of the groups has more than 5 C atoms (aromatic ring) to promote soly. in the oil; another one of the groups should be a straight C_{10} or more aliphatic chain to improve the capillary qualities. X represens a negative group: OH, NO_3, SO_4, alkyl sulfate, sulfonate, palmitate, oleate, naphthenate, etc. The amt. of sulfonium compd. used is up to 5%.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Purified wood cellulose. Geo. A. Richter. *Ind. Eng. Chem.* **32**, 324–8(1940).—Specific details regarding the prepn. and properties of purified wood cellulose are given. F. A. Simmonds

The mechanism of deformation and the fine structure of hydrated cellulose. XV. Optical polarization analysis of the process of deformation of fibers of isotropic hydrated cellulose. 1. Double refraction in the unswollen condition. P. H. Hermans and P. Platzek. *Z. physik. Chem.* **A185**, 200–8(1939); cf. *C. A.* **32**, 9482[1]; **33**, 7174[4].—Fibers of hydrated cellulose were prepd. from 4 and 8% viscose, stretched, and treated in various ways.

They were then dried, cut wedge-shaped and examd. under a polarizing microscope with Na light. The sp. double refraction increases with increase in the degree of swelling to which the fiber was subjected before drying. As a function of the degree of extension to which the fiber was initially subjected, the optical anisotropy measured in the dried condition behaves qualitatively in the same way as does the anisotropy in the swollen condition. T. H. D. 1

Transition of hydrate cellulose into native cellulose. III. Through molecular compounds of cellulose. Teruitiro Kubo. *Cellulose Ind.* (Tokyo) **15**, 99–104(in English, 13–19)(1939); cf. *C. A.* **33**, 7558⁹.—Hydrazine-cellulose II and ethylenediamine-cellulose II, prepd. from viscose rayon by immersion in a soln. of the appropriate base, are completely converted into native cellulose by immersion in glycerol for 3 hrs. at room temp., followed by heating at 250° for 3 min. The direct conversion of hydrate into native cellulose is more difficult, and the difference is ascribed to the solvation of the mols. of the diamine-celluloses, which permits freer relative movement. 2

B. C. P. A.

Method for estimating the internal surface of cellulose by means of thallous ethylate. Chapin A. Harris and C. B. Purves. *Paper Trade J.* **110**, No. 6, 29–33(1940).—EtOTl, in dil. Et_2O or C_6H_6 soln., and dry mercerized ramie gave a Tl cellulose deriv. in which the Tl replaced hydroxyl H; more Tl was occluded in varying amts., and in an undetd. state. The reagent failed to penetrate into the interior of the cellulose micelles, its action being restricted to the more amorphous regions or to the effective internal surfaces of the fiber. Methylation of the Tl cellulose deriv. gave a product contg. 1.45 ± 0.3% of OMe; the H in 1 OH in every 40 had thus been replaced by Tl and the effective internal surface of the mercerized ramie was accordingly about 4×10^6 sq. cm. per g. Semiquant. data suggested that each OH group on the internal surface was capable of attaching 1 mol. of H_2O or Et_2O; the formation of the resulting fairly stable unimol. adsorption films was thus explained. Preliminary results with purified but unmercerized ramie and with a drastically mercerized specimen gave 0.24 and 18.4% as superficial OH, with corresponding internal areas of 3.7×10^4 and 2.9×10^6 sq. cm., resp.; these data were not comparable because the 1st sample contained more β- and γ-cellulose. A cotton regenerated from cuprammonium had an area of about 4×10^6 sq. cm. per g. The new estn. of the internal surface of cellulosic materials was not unduly long or difficult; it gave reasonable results reproducible to ±20% and was sensitive to the pretreatment of the sample. A. P.-C. 3 4

Experiments to make visible the inner structure of cellulose fibers by depositing extraneous materials. Ernst Kulnel. *Kunstseide u. Zellwolle* **22**, 3–7(1940).—Freshly prepd. ammoniacal colloidal Au soln. was impregnated into fibers in the presence of NaOH soln. Care was taken to exclude light to prevent the Au from pptg. After rapidly filtering the Au was deposited in the fiber by reduction with acidified CH_2O. The fibers were dried at 105°, covered with oil of cloves as the embedding agent at 100° and allowed to cool. Photomicrographs are reproduced showing 4 possible ways of deposition: on fiber surface, just under the surface, throughout the fiber and in the center only. *Ibid.* 35–8.—The treatment with Au salts previously described was repeated with Ag salts. For reduction, photographic developers can be used, such as Amidol, in the presence of a protective colloid. Photomicrographic cross sections of treated fibers showed that deposition had taken place throughout the fiber. Also $BaSO_4$ and colloidal S were thus deposited in the fiber. The first treatment in every case must be in the presence of NaOH both to swell the fiber and to dissolve out some component that makes room for the particles. K. believes that the method will lead to a better understanding of the orientation of fiber elements and the presence of short- or long-chain mol. groups. It may also be possible to use this method as an analytical tool in the estn. of the degree of polymerization. • M. P. 7

Cellulose acetate production in U. S. A. Herbert Chase. *Brit. Plastics* **11**, 381–4(1940). G. G.

Increasing the resistance to light of cellulose acetate films. M. M. Moiseev and M. S. Sverdlin. *Org. Chem Ind.* (U. S. S. R.) **7**, 519–21(1939).—The yellow discoloration of cellulose acetate films on exposure to light was traced to the impurities of Fe and Ca in tap water used in washing of cellulose acetate. The transparency and resistance to light were considerably increased by the use of distd. water in washing. Excessive washing under all conditions gives inferior films. Chas. Blanc

Yield and viscosity of holocellulose and some of its cellulosic fractions. Wm. G. Van Beckum and Geo. J. Ritter. *Paper Trade J.* **109**, No. 22, 107–9(1939); cf. *C. A.* **33**, 4017⁸.—Holocellulose gives high viscosities in spite of the fact that it contains appreciable amts. of hemicelluloses. Its high viscosity indicates that it contains longer cellulose chains than does either the Cross and Bevan cellulose or raw hydrolyzed holocellulose on the basis of the wood. The alk. treatment employed for the isolation of the α-cellulose suggests that an alk. treatment dissolves the short-chain material and leaves as a residue the long-chain material. An acid treatment, on the other hand, dissolves short-chain material and also degrades the residue as is shown from the viscosity data on the hydrolyzed holocellulose and its α-cellulose. Cross and Bevan cellulose and its α-cellulose have viscosities between those of the holocellulose and the hydrolyzed holocellulose, which fact indicates that the action of aq. 2.0% Na_2SO_3 is less drastic than that of aq. 1.3% acid on cellulosic material. High hemicellulosic content of a cellulosic material is not an indication of a material of low viscosity, nor is approx. the same hemicellulosic content of 2 cellulosic materials from the same wood an indication of similar viscosities. A. Papineau-Couture 8

Macromolecular compounds. CCXXXVII. The destruction of cellulose by microörganisms. H. Staudinger, M. Staudinger and H. Schmidt. *Zellwolle, Kunstseide Seide* **45**, 2–4(1940).—Microscopic examns. of decaying wood show that the cell walls disintegrate. Although the lignin is destroyed, the av. degree of polymerization of the wood may still be such that useful fibers can be produced from it. Leopold Scheflan 9

Chemistry of the plant cell wall. IX. Further studies on the location of lignin, cellulose and other components in woody cell walls. W. M. Harlow. *Paper Trade J.* **109**, No. 18, 38–42(1939); cf. *C. A.* **33**, 2939⁸.—The investigation was carried out by observing the effect of various solvents applied to cell walls. Wood sections delignified by standard methods do not macerate in the sense that each cell seps. from those touching it, even though the intercellular material is, apparently, all removed; the slightest agitation of such immersed delignified sections is sufficient to cause their dissocn. into large or small cell aggregates depending on the species in question. Treatment of delignified sections with solvents for polyuronides and hemicelluloses had no further macerating action on the woods studied. In delignifying wood, the layer most retentive of lignin seems to be the primary wall. This is shown by its presence as a network in 72% H_2SO_4 (and at a later stage in Schweizer's reagent), after the intercellular substance has been removed, while at the same time the secondary walls are completely sol. in these reagents. Primary walls may be delignified to a point where they are completely sol. in 72% H_2SO_4, but are insol. in Schweizer's reagent; they may then be made sol. in the latter reagent by further delignification, treatment with hemicellulose solvents, or, in some cases, by treatments with solvents for polyuronides. Secondary walls, delignified to the point where they are sol. in 72% H_2SO_4 but insol. in Schweizer's reagent, may be rendered sol. in the latter by further delignification. Soly. of cell walls in Schweizer's reagent is probably a better test for the complete removal of "encrusting substances" (particularly lignin) than is soly. in 72% H_2SO_4. Treatment of wood sections of several dicotyledons with vanillin failed to cause the secondary wall of fiber tracheids to give a coherent structural pattern when subjected to 72% H_2SO_4, even though untreated sections had a strong Maüle color test. 10

A. Papineau-Couture

Chemistry of lignin. I. The existence of a chemical bond between lignin and cellulose. A. J. Bailey. *Paper Trade J.* **110**, No. 1, 29–34(1940).—Digestion of aspen and jack pine wood in BuOH-H_2O mixts., buffered to prevent hydrolysis, removed all of the lignin from aspen and 80% of the lignin from jack pine. The remaining jack pine lignin was easily removed in the same solvent made 2% in NaOH. The lignin fractions appeared to be similar or identical, the difference being that one was in chem. combination with cellulose, the other uncombined. Yields under various conditions of digestion were detd., and changes in the wood caused by digestion were followed by detg. the analytical consts. of the residues from digestion. All tests indicated that lignin may exist partly in true chem. combination with cellulose and partly free, or entirely uncombined with cellulose, the detg. factor being the species of the wood. **II. Butanolysis of wood.** *Ibid.* No. 2, 29–32.—Addn. of 2% NaOH to the BuOH-H_2O mixts. accelerated the delignification 5–16 times. With this type of liquor, almost white pulps contg. only 0.33% lignin were obtained in yields of 43–50%, by cooking aspen for 15 min. and jack pine for 1 hr. Time-yield-alkali-lignin content curves are shown for the entire practicable range for the pressures used. The alkali functions as a catalyst in the lignin-BuOH condensation rather than as a reactant. It is suggested that the mechanism of the pulping consists in one minor reaction, the splitting of the combined lignin from the cellulose, and 2 major reactions: the condensation of BuOH and lignin, and the hydrolysis of the cellulose, the latter destructive, the former essential, and both increasing with alkali concn. Exptl. evidence is adduced in support of this hypothesis. BuOH was easily recovered from the final liquor, 95% being recovered by sepg. the immiscible layer and several % more by distg. only 10% of the total liquor. A. Papineau-Couture

Hydrogenation of lignin in aqueous solutions. Elwin E. Harris, Jerome Saeman and E. C. Sherrard. *Ind. Eng. Chem.* **32**, 440–1(1940); cf. *C. A.* **33**, 854[8].—Methanol-lignin (cf. *C. A.* **32**, 5794[4]), alkali lignin from aspen, H_2SO_4-lignin and cellosolve lignin obtained by heating extd. sawdust with cellosolve contg. 3% HCl for 24 hrs. are hydrogenated in aq. or 1% alk. solns. or suspensions with Raney Ni as catalyst. At 1500–2500-lb. pressure and 225–50° the hydrogenation is completed in 6–10 hrs., approx. 35 mols. H being taken up by each equiv. wt. of lignin (900 g.). The hydrogenation products found are identical with those obtained in the earlier work. F. E. Brauns

Viscose. IV. Compression of mercerized pulp in the steeping press. Mituo Huzii. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 406–7(1939); cf. *C. A.* **33**, 1493[7].—The relation is studied between the compn. of alkali cellulose (I), the ratio of I to original pulp and the thickness of the mercerized pulp under pressure. The compn. of I depends more or less on all of these factors. To obtain a uniform I, it is very important that the wt. of cellulose in pulp and the thickness of the mercerized pulp in the steeping press are always const. regardless of the moisture content of the pulp. F. E. Brauns

Coagulating and chemical action of precipitating baths on the formation of viscose filaments. S. N. Danilov, N. F. Gintse, O. F. Plyushch and I. S. Samarskiĭ. *Org. Chem. Ind.* (U. S. S. R.) **7**, 511–17(1939); cf. *C. A.* **29**, 8325[7]; **33**, 5179[7].—The results of previous investigation are reviewed and some addnl. exptl. data are given. Chas. Blanc

A case of occupational asthma from rayon. Vico Liverani. *Rass. med. ind.* **10**, 735–41(1939).—A worker in a factory making rayon from poplar wood became ill and subject to violent fits of coughing characteristic of asthma. The waste from the pulp was investigated and the various proteins found were tested by the patch test. When the one responsible for the asthma was found, the man was desensitized and thereafter no longer suffered from the attacks. M. Schubert

The literature of wood and wood technology. A. J. Bailey. *Paper Trade J.* **109**, No. 22, 97–104(1939).—The necessity of keeping abreast of all current scientific developments through indexes is pointed out. In the absence of a comprehensive bibliography under a single cover and with proper subject and author indexes to make all past information available, notes are given pointing out the bibliographies, abstract journals, indexes and other forms of literature, the devices for keeping informed on new publications as they appear, and the means of obtaining information by using the various services provided by the large libraries. 87 references. A. P.-C.

Existence and nature of fiber membranes. H. F. Lewis, F. E. Brauns and M. A. Buchanan. *Paper Trade J.* **110**, No. 5, 36–8(1940); cf. *C. A.* **33**, 855[8].—A method was developed for isolating the skin-like bodies left behind as a result of careful swelling of pulp fibers with cuprammonium soln. The cellulose fraction of the fiber is peptized with cuprammonium, and the action of pectic solvents (with the exception of dil. acids) has little or no effect on the viscosity of a soln. of such treated pulps in this solvent. Raw kraft pulps contg. up to 22% lignin have middle lamellar lignin on the outer walls; when the lignin content is reduced to 8.6%, this has largely disappeared. The residual lignin in a kraft pulp contg. 8.6% lignin appears to be assocd. with the amorphous materials sepg. the cambial layer from the secondary wall and sepg. the various layers of cellulose in this secondary wall. It seems improbable that these membranes represent a continuous skin having a physiol. function; rather it would appear that they have resulted from a different chem. activity at the time of their deposition or have reached their location by infiltration. The residues isolated from unbleached sulfite pulps are more than half lignosulfonic acid, with much smaller amts. of carbohydrates; the hydrolyzed residues from the sepn. of the lignosulfonic acid are in part reducing and in part nonreducing sugars. The residues isolated from bleached sulfite pulps are Cu compds. of carbohydrate derivs. One-third of the residue is Cu; 97% of the remainder can be detd. after hydrolysis as reducing sugar. The carbohydrate after removal of the Cu forms a white gel, which on drying yields a white starch-like powder contg. 44.2% C and 6.25% H. Purification of the bleached pulp with hot 1% alkali reduces the amt. of this residue from 1% to 0.1%; the viscosities of the pulps before and after this extn. are much the same. A very highly purified wood pulp with 0.70% pentosan, 0.049 Cu no. and 99.1% α-cellulose swells as though there was no cementing substance between the cellulose layers in the secondary wall; this pulp contains practically no cuprammonium-insol. material, nor can it be made to yield paper after beater treatment. A. P.-C.

Arrangement of the cellulose crystallites in ray cells of white oak as determined by x-rays. S. T. Gross, G. L. Clark and G. J. Ritter. *Paper Trade J.* **109**, No. 23, 37–8(1939).—By means of thin sections of white oak ray cells, a specimen was built that enabled the detn. of the arrangement of the cellulose crystallites by x-rays. The cellulose crystallites deviate about 30° from the vertical crosswise direction in the ray cells of white oak, which arrangement is in general agreement with that found by microscopical means. This finding indicates that the ray cells of white oak will shrink and swell considerably in their longitudinal and tangential directions; this is also in general agreement with the findings obtained by microscopical means. A. P.-C.

The preparation of a wood sample for chemical analysis. W. E. Cohen and A. W. Mackney. *J. Council Sci. Ind. Research* **12**, 365–77(1939).—Wood samples prepd. by using a mill with a cutting action (Wiley mill) and a mill with an impact action (Christy and Norris mill) were examd. Conclusions: The effect of very fine comminution permits some degradation of Cross and Bevan cellulose in subsequent analysis; it is possible to accept for analysis either the 60–80-mesh fraction or a sample of particle size passing through a 60-mesh sieve. The former is preferable because of the more uniform particle size, but in case of doubt, where woods may contain considerable amts. of extraneous material, like jarrah, it would be safer to use the 60-mesh sample. Alfred L. Kammerer

Effect of mechanical gelatinization on the solubility of wood in cuprammonium solution. John Levy and Edwin C. Jahn. *Paper Trade J.* **109**, No. 23, 45–9(1939).—The percentage solubilities of northern white pine mech. pulp in cuprammonium soln. of standard strength for TAPPI viscosity measurements were as follows after various treatments: no treatment, 15.8; hot 4% NaOH soln., 21.8; hot 4% NaOH soln., followed by beating in a rod mill in 2% NaOH soln. for 40 hrs., 32.2; beating in a rod mill in water for 40 hrs., 27.15. The great increase in soly. caused by mech. gelatinization, which greatly increases the surface area of the wood, increases the soly. of the cellulose fraction of the wood. Alk. treatment increases soly. presumably as a result of the softening and swelling of the wood particles and the slight removal of lignin and hemicellulose. Cuprammonium soln. exerts a selective solvent action on the constituents of both gelatinized and ungelatinized wood. The sol. fractions are over 90% cellulose; about 50% of the original cellulose, 5.5% of the original lignin and 13% of the original pentosans are dissolved from northern white pine groundwood which has been mechanically gelatinized in dil. alkali. A. Papineau-Couture 1 2

The determination of water in wood. R. Darnley Gibbs. *Pulp Paper Mag. Can.* **41**, 31–4(1940).—A brief review of methods for the detn. of moisture with a discussion of their suitability for wood. 17 references. A. P.-C. 3

University of Washington completes new pulp laboratory. K. A. Kobe. *Paper Ind. Paper World* **21**, 865–7, 872(1939).—A description of the lab. and its equipment. A. Papineau-Couture 4

Methods used at the Forest Products Laboratory for chemical analysis of pulps and pulpwoods. M. W. Bray. *U. S. Forest Products Lab.*, Mimeographed Rept. R19 (1939).—A revision of methods. Cf. *C. A.* **23**, 976. C. E. Curran 5

The determination of methoxyl groups in pulp and plant materials. Quinton P. Peniston and Harold Hibbert. *Paper Trade J.* **109**, No. 17, 46–8(1939).—A detailed description is given of the technique of a modification of the Vieböck and Schwappach method (*C. A.* **25**, 474, 896), which is particularly well adapted to the detn. of OMe in paper pulp A. Papineau-Couture

The use of the ultraviolet quartz lamp for the analysis of pulp and paper. V. Gruenman. *Papier* **42**, 889–91 (1939).—A brief description of the use of filtered ultraviolet light for the detn. by fluorescence of TiO_2 and of rosin spots in paper. A. Papineau-Couture 6

Pulp woods and pulps. II. Manufacture of pulps from Manchurian spruce, fir and aspen. Nobuhiko Migita. *Cellulose Ind.* (Tokyo) **15**, 54–8(1939); cf. *C. A.* **32**, 8133⁷.—The sulfite cooking of *Picea obovata*, Ledeb. (I), *Abies nepheroleþis*, Max. (II), and *Populus maximowiczii*, A. Henry (III), was investigated. Seven different samples of each were digested with a liquor contg. 4.3–6.2% of total SO_2, at a max. temp. of 145–55°, max. pressure of 4.5–6.5 kg./sq. cm. for 9–15 hrs. In the case of the unbleached pulps I gave the highest % yield (46.7–52.4) and also the highest lignin content (1.04–6.98%), while III, which yielded only slightly less than that of I, gave a pulp with the highest α-cellulose content (86.8–89.4%). On bleaching, III shows the least loss and the highest α-cellulose content in the pulp (85.2–89.0%), while in these respects I is only slightly inferior to III III has the highest and II the lowest pentosan content. All three woods, however, are easily digested, III being the most amenable to pulping by the sulfite process. B. C. P. A. 7

Average yields of wood pulp from various species of wood. *U. S. Forest Products Lab.*, Tech. Note **191**, (Dec., 1939). C. E. Curran 8

Wood pulp. X. Results of cooking experiments with lauan woods. Eisio Hu. *Cellulose Ind.* (Tokyo) **15**, 52–3(in German, 7–8)(1939); cf. *C. A.* **33**, 6044².—Red and white lauan woods were digested with $Ca(HSO_3)_2$ at a max. digester pressure of 8 atm. and max. temp. of 140° for 8 to about 9½ hrs. The liquor contained 6% of total SO_2 and 1.1% of CaO. The woods yielded 44–47% of unbleached pulp, having 1.9–2.7% of lignin, about 94% of α-cellulose, and R20 no. 2.8–3.3. As with all deciduous woods, the max. pressure reached during the cooking plays a very important part in the extent to which the pulps are liberated. B. C. P. A. 9

Pine pulpwood from logging tops. E. O. Siecke. *Paper Trade J.* **109**, No. 26, 28–9(1939).—The tops of pine saw logs can be and are successfully used commercially for pulping by the sulfate process. A. Papineau-Couture

Groundwood pulp control. C. G. Malcolm. *Pulp Paper Mag. Can.* **40**, 635–7(1939).—A discussion dealing briefly with stone burr, temp., consistency, dirt, slivers and oil. A. Papineau-Couture

Effect of wood-stone contact area in the groundwood process. E. R. Schafer and J. C. Pew. *Paper Trade J.* **109**, No. 20, 39–42(1939); cf. *C. A.* **33**, 9630⁴.—The effects of changing the area of the wood-stone contact were studied in the exptl. grinder of the U. S. Forest Products Lab., by varying both the width of the wood in the pockets and the no. of pockets in operation. Increasing the zone length (around the periphery of the stone) up to a certain extent improved results, but too large a zone proved a detriment. Exact formulation of the relationships is difficult on account of the numerous factors involved. The increase in consistency and temp. along the contact zone appears to be of importance. These factors in turn depend on many of the fixed conditions of the expt., such as stone surface, consistency and grinding rate. Aside from these factors the results suggest that the intimacy of contact between the wood and stone is affected by the magnitude of the contact area even when the unit pressure remains the same. A. Papineau-Couture

Cellulose. Preparation of pulp from rice straw by cooking with alkali, and by the sulfite process. T. Kimura. *Cellulose Ind.* (Tokyo), **15**, 105–7 (1939).—**XI.** The most satisfactory cooking conditions for prepg. pulp from rice straw are 2 hrs. at 140° with 10 vols. of 1% aq. NaOH, preceded by a cook at the same temp. with the spent liquor from a previous prepn. **XII.** *Ibid.* 108–110.—The ash and lignin contents of pulp precooked with spent alkali are less than those of pulp precooked with H_2O, and at 140° are less than at 100°. The breaking load and extensibility of precooked pulp are less than those of single-process pulp. **XIII.** *Ibid.* 111–12.—The sulfite process gives pulps with higher ash and lignin contents, but less pentosan, than the alkali process. Their strengths are low, and prolonged treatment causes darkening. B. C. P. A.

Multistage alkali digestion of straw. K. Akagi. *Cellulose Ind.* (Tokyo) **15**, 59–60(in German, 11)(1939).—Rice straw was digested in two stages with NaOH. The yield was 23%, and the pulp light in color but with a relatively high content of ash (60–62.5% of SiO_2). On account of the large no. of parenchyma cells and silicous matter present, however, rice straw is unsuitable for viscose, and as a fibrous material it is stated to be almost valueless. Wheat straw is considered to yield superior pulp to rice straw, but it is available in Japan in much smaller quantity. B. C. P. A.

Chlorination pulping of spruce wood. Carl T. Welte and C. E. Libby. *Paper Ind. Paper World* **21**, 1075–81 (1940).—It was possible to produce a satisfactory white pulp from spruce wood by a chlorination process. The min. alkali treatment that could be used to prep. spruce for defibering prior to chlorination on a lab. scale was 10% of NaOH. It was impossible to obtain a good white pulp by single-stage treatments of the half stock with either gaseous or aq. Cl if only the min. alkali pretreatment was employed. Two-stage and triple-stage chlorinations produced a good white pulp from the min.-alkali half stock The optimum consistency of half stock for gaseous Cl treatment was 25% oven-dry. Treatment with gaseous Cl gave a higher pulp yield than treatment with aq. Cl. There was no pronounced difference in the strength characteristics of pulp prepd. by either gaseous or aq. Cl for the 1- and 2-stage processes; 3-stage chlorination gave much stronger pulps by the gaseous-Cl than by the aq.-Cl process. Bleach consumption of pulps prepd. with aq. Cl

is lower than that of similar pulps prepd. with gaseous Cl. Cellulose degradation occurs to very nearly the same extent in the pulps prepd. by the single-stage treatment with either gaseous Cl or aq. Cl; in multi-stage chlorination, aq. Cl causes much more cellulose degradation than gaseous Cl. A. Papineau-Couture

Bleaching-procedure design for high-white high-strength kraft pulps. Warren A. Chilson. *Paper Trade J.* **109**, No. 25, 29–31(1939).—The following is suggested as a suitable procedure for the production of high-white high-strength kraft pulp: (1) combined chlorination and hypochlorite treatment, wash; (2) hypochlorite treatment, wash; (3) caustic extn., wash; (4) water soak, wash; (5) hypochlorite treatment, wash; (6) acid adjustment and final wash. The advantages and disadvantages of combining chlorination and hypochlorite reactions are discussed, and the relative merits of batch and continuous operations are briefly considered. A. P.-C.

New methods of continuous causticizing [for kraft-pulp manufacture]. J. R. Lientz. *Paper Mill* **61**, 18–20 (Dec. 24, 1938).—The Swenson continuous causticizing system is described and its advantages are pointed out. B. C. P. A.

Comparison of kraft and sulfite [pulps] on paper machines. E. W. G. Cooper. *Pacific Pulp and Paper Ind.* 12, 20–2(Dec., 1938).—The characteristics and paper-making behavior of bleached and unbleached kraft and sulfite fibers are contrasted. B. C. P. A.

New ideas on the use of salt cake in kraft pulp mills. Walter L. Savell. *Paper Trade J.* **109**, No. 24, 18–22 1939).—What appear to be opportunities for improvement in the chem. end of the kraft pulping process are pointed out, more particularly SO_2 recovery from stack gases and the use of a new "synthetic salt cake" (a manufd. product based on a standard alkali and S sintered together in proportions to make the chem. equiv. of salt cake in Na_2O and S). A. Papineau-Couture

Weight factors of beaten pulps. John H. Graff. *Paper Trade J.* **110**, No. 2, 37–40(1940).—Beating has little or no effect on the relative wt. factor of a pulp, but the species of wood, especially in respect to its geographical location, is a factor of great importance. The tentatively proposed wt. factors used by the Institute of Paper Chemistry (Appleton, Wis.) require very little modification except that western hemlock and southern pine pulps must be considered separately. A. Papineau-Couture

Microdissection of paper-pulp fibers. Charles W. Hock and Wm. Seifriz. *Paper Trade J.* **110**, No. 5, 31–2 (1940).—After boiling in water and subsequently treating with H_3PO_3, the fibers of 7 kinds of paper pulp were examd. microscopically and handled with microdissection needles. A typical fiber consists of many fine fibrils running parallel with the axis of the fiber; these fibrils are wrapped by an outer winding encircling the fiber as a whole, and bordered by an inner winding which subtends the lumen of the fiber. Balloon formation is the result of an uneven weakening of the interfibrillar forces of the outer winding, thereby allowing the longitudinal fibrils to push through. The breaking strength of paper pulp is detd., in part, by fiber structure. The strength of wood fibers is due primarily to many longitudinal fibrils; this is augmented by an outer and inner fibrillar winding. A. Papineau-Couture

The drainage resistance of papermaking pulps. W. O. Hisey and C. H. Heigl. *Paper Trade J.* **110**, No. 6, 34–40 (1940).—The flow of water through a forming mat of fibers is analyzed on the basis of Poiseuille's law. An equation is derived for the detn. of the resistance to flow of water under conditions of const. rate of flow, and this equation is tested on pulp samples beaten to various degrees. The equation was valid for the conditions of testing, and the test method described could be used to det. the sp. resistance of pulp fibers to fluid flow and also to det. the compressibility of pulps. The test method described would appear to have considerable value as a routine or research method of detn. of pulp properties. A. Papineau-Couture

Water retention of beaten and gelatinized pulp. Arthur Sedoff, C. V. Holmberg and Edwin C. Jahn. *Paper Trade J.* **109**, No. 26, 42–9(1939).—The percentage of water retained by wet pulp increases with increased beating. Increased pressures up to 3000 lb./sq. in. decrease the percentage of water retained for any const. time of pressing; above 3000 lb., variation in pressure has little effect on the percentage of water retained. Increased time of pressing at any const. pressure decreases the water content; in general, the shorter the time pressed, the greater the differentiation in water content due to beating. Beating has no effect on the water retained if the pulp is subjected to pressure for 4 hrs. or longer. The percentage of linear shrinkage of pressed pulp cakes increases with beating; it correlates with the percentage of water retention to give an approx. straight-line relationship for pressures above 3000 lb. The stiffness of the fibers or their resistance to crushing and deformation in unbeaten pulp is overcome at about 3000 lb.; beating decreases the pressure required to deform the fibers. Pressures up to 3000 lb. cause fiber deformation and the flow of free water; at approx. 3000 lb. both of these resistances are overcome and higher pressures force out capillary water. Detg. the percentage of water retained by pulp pressed at 4000 lb. for 10 min. gives a good measure of beating changes for drastically beaten or gelatinized pulp. Detg. the percentage of water retained in a sheet couched from a standard sheet machine gives a good index of its degree of beating. A. P.-C.

Application of a quantitative technique to the evaluation of color stability of bleached pulps. Influence of machine drying and natural aging on this evaluation. James W. McIntyre. *Paper Trade J.* **109**, No. 24, 29–37(1939). —The effect of temp. and humidity on the rate of discoloration of bleached sulfite pulp was studied by means of specially constructed equipment. Discoloration rates were detd. by the method of Tongren (*C. A.* **32**, 9492[6]). A min. point in the rate of discoloration was found at about 20% relative humidity at 85° and 95°, resp.; other temps. were not investigated thoroughly. Extension of the humidity-rate of discoloration study at 95° to include other types of pulp showed that the position of the min. rate of discoloration was variable, a soda pulp showing no min. rate down to 2.0% relative humidity; hence, the relative values of accelerated discoloration rates of various pulps are dependent on the humidity of the aging atm. On the theory that rates of discoloration detd. at a humidity which would maintain a normal moisture content in the sheets at the aging temp. should parallel most closely the results of natural aging, 55.4% relative humidity at 95° was arbitrarily adopted as a standard aging condition; under these conditions, a moisture content of about 5.7% was maintained in the sheets during aging. A study of some of the variables of pulp handling prior to accelerated aging tests revealed that heat-drying of bleached sulfite pulp prior to hand-sheet prepn. caused a marked increase in subsequent color stability. The increase in color permanency is not due to the reduction in reflectance which occurs during the machine-drying of pulp. When dry sheets are heated, although they may undergo a loss in reflectance comparable to that occasioned by machine-drying, their rate of accelerated discoloration is unchanged. It would therefore seem that in the presence of heat and moisture, some reaction occurs in sulfite pulp which, although reducing the reflectance somewhat, tends to stabilize this property to a marked extent. In an evaluation of the effect of wet storage of pulp on subsequent accelerated aging behavior, 30 days' storage of a bleached sulfite pulp as wet laps reduced the accelerated discoloration rate of air-dried hand sheets prepd. therefrom to 73.0% of the value for hand sheets prepd. from the freshly bleached pulp. Dry storage of air-dried hand sheets made from a slush pulp, although causing a marked reduction in reflectivity, caused no change in subsequent accelerated discoloration rate. A slight increase in aging rate, after similar storage, was observed for air-dried hand sheets prepd. from machine-dried pulp. Natural aging studies carried out on the various pulps showed that the results of the accelerated tests at 95° and 55.4% relative humidity paralleled the rates of naturally occurring discoloration

better than did the results of the accelerated tests at 2.0% relative humidity. The relation of natural discoloration rate to accelerated discoloration rate as detd. was not const., since the natural aging rate was subject to greater percentage change by reason of prior pulp treatment than was the accelerated rate. A. Papineau-Couture

Sulfate pulping of silver fir. Effect of chemical concentration and of wood selection on yield and pulp quality. Mark W. Bray, J. S. Martin and S. L. Schwartz. *Paper Trade J.* **109**, No. 18, 29–36(1939).—Decreasing the concn. of chemicals in the cooking liquors from 80 to 20 g. per l. resulted in a kraft pulp of max. yield and strength properties at approx. 50 g. per l. total initial concn. when the digester was heated with indirect steam. Cooking to equal yield by increasing the time of digestion for lower chem. concns. did not result in pulps of equal strength and bleach requirement to those made at this particular concn. For the production of kraft pulps of high strength characteristics, wood taken from the upper portion of the trunk gave somewhat better pulps than that taken from the butt logs. Slab wood, consisting of all sapwood, gave better pulps than wood in which a greater proportion of heartwood was present. A. Papineau-Couture

Sulfidity effect in the sulfate pulping of Douglas fir. Mark W. Bray, J. Stanley Martin and S. L. Schwartz. *Tech. Assoc. Papers* **22**, 382–7(1939); *Paper Trade J.* **109**, No. 17, 40–5(1939).—The sulfidity of liquor with a 20% free alkali (as NaOH) content was varied from 0 to 100% under 1 set of cooking conditions. Liquors of 100% sulfidity (Na_2S only) can be satisfactorily used for pulping Douglas fir, provided sufficient chemical is present to effect delignification. Na_2S has a sp. effect in pulping in addn. to its caustic content made available through hydrolysis. While this chemical may act to some extent as a buffering agent, the sulfide or the hydrosulfide ion appears to act mainly as a substance of high reactivity toward lignin or encrusting substances in wood. Replacement of NaOH, therefore, with Na_2S at const. initial alky. results in a progressive decrease in yield and bleach requirements of the resulting pulps from Douglas fir up to sulfidities of 34%; further increases in sulfidity up to 100% result in only slight changes in yield and pulp quality. A. P.-C.

Use of swamp black gum sulfate pulps for high-grade papers. Charles Carpenter and G. A. Ritter. *Paper Trade J.* **110**, No. 3, 29–31(1940).—Swamp black gum sulfate pulps suitable for bond papers were made with 16% of active alkali in cooking times of 2–3.5 hrs. Yields were 48–50%. Bleaching consumed 3–6% Cl in 3 or 4 stages. Bleached swamp black gum sulfate pulps were made into bond papers of excellent formation and high strength characteristics; 20 substance sheets (54-lb. 25 × 40–500), (46-lb. 24 × 36–500) tested approx. 35–45 pts. Mullen, 65–95 g. tear and 400–1500 double folds. A. P.-C.

Recovery in sulfate pulp mills. G. Edling. *Pulp Paper Mag. Can.* **40**, 681–5, 734–8(1939).—A description of the Tomlinson system, with a discussion of the results obtained with it in Sweden during the last 2 or 3 yrs. A. P.-C.

The suitability of red pine for the manufacture of sulfite pulp. John Studeny and C. E. Libby. *Paper Trade J.* **109**, No. 20, 29–35(1939).—In the belief that pitch troubles encountered by previous investigators could be avoided by using young trees, 5 series of sulfite cooks were made by using a liquor contg. 6.3% total and 5.0% free SO_2 and a liquor-wood ratio of 6:1. Young red pine wood was readily delignified at low temps. (135–40°) following a 2-hr. penetration period; total cooking time of 10 hrs. was sufficient and gave 45% yields, while 8-hr. cooks gave up to 50% yields. Ca-base cooks of 10-hr. duration at 135–40° gave the strongest, most easily bleached pulps in the best yields; these pulps contained 80–85% α-cellulose, with very little residual lignin, and a fairly low pitch content. Dolomitic liquors gave "soft" pulps, which were not as strong as those made with Ca base, while Na-base cooks gave very dark-colored pulps which were hard to bleach. The best pulps obtained from young red pine wood in these expts. compared very well with one of the higher grades of com. sulfites. With the same liquor under similar conditions, more mature red pine wood gave an excessive amt. of screenings owing to incomplete penetration of the liquor, caused by the high pitch content of the old wood. A. Papineau-Couture

Digesting sulfite pulp and getting a high yield of alcohol. David Johansson. *Svensk Papperstidn.* **42**, 582–8(1939); cf. *C. A.* **18**, 3113; **23**, 2569; **29**, 1628[6].—Emergency production of alc. by simple sugar formation from spruce chips in a sulfite digester with dil. H_2SO_3 has little advantage because the same yield of alc. (60–70 l. of 100% alc. per ton of absolutely dry wood) can be obtained from the wood by modified sulfite digestion. The alc. yield from *sulfite waste liquor* increases with the lowering of the Ca content of the digesting acid and with the use of a pulp with a low Cl no. For the highest yield of alc. per digesting unit easily bleached pulp must be made by one-step digestion, with lowest possible Ca content, and in the shortest possible digesting time. The resulting pulp is of second quality but fully suitable for certain kinds of paper. Long-continued digestion produces a pulp of low viscosity which because of the character of the fiber should be suitable as "fodder-cellulose." Long-continued digestion lowers the yield of alc. per digesting unit. Exptl. conditions are described and numerical data are given in detail. Wilhelm Segerblom

Yield of alcohol from waste liquor from sulfite digesting and retention of the strength of the pulp. Carl R. Bergson. *Svensk Papperstidn.* **43**, 2–4(1940).—B. discusses the results of D. Johansson (cf. preceding abstr.) and H. Nihlén (cf. following abstr.). W. S.

Investigation of two-step sulfite digesting according to the NAF-Hägglund method. Hugo Nihlén. *Svensk Papperstidn.* **42**, 593–9(1939).—The simplified app. used in the NAF-Hägglund multiple-step method for producing sulfite pulp was tested on a lab. scale. This gave the same yield of pulp and pulp of the same strength as was obtained in 1-step digesting with the usual tech. Ca content. The acid concn. needed for the 2-step digesting depends on how far down the pulp is to be cooked. A very low Ca content in both steps may be used in making easily bleached pulp; a doubling of the alc. yield may thus be expected. A higher Ca content must be used to get a harder and stronger pulp, but under these conditions the alc. yield decreases. In general twice as large a yield of alc. may be expected from multiple-step digesting as from 1-step digesting without washing, based on pulp of the same strength in each case. Ten tables of numerical data and 3 graphs give the quant. results from the exptl. comparison of the 2 methods. Wilhelm Segerblom

Acidproof masonry in the sulfite industry. I. Björnstad. *Svensk Papperstidn.* **42**, 609–11(1939).—The formation of cracks in the lining of digesters is discussed. The grading of the raw materials, as well as their chem. compn., is essential for a lining that will not allow the digesting acid to reach the metal shell of the digester. A new mixt. (compn. not given), termed AX-III, has been prepd. which is claimed to give good results W. S.

Degree of efficiency of sulfite acid towers. O. E. Sylwan. *Svensk Papperstidn.* **43**, 6(1940).—Polemic. Nihlén's criticisms (cf. *C. A.* **34**, 1171[7]) of S.'s article (cf. *C. A.* **33**, 8988[8]) are deemed not justified. Wilhelm Segerblom

Pulp mills and fisheries. Sten Vallin. *Medd. Statens Undersökn.-Forsoksanst. Sötvattensfisket, Kgl. Lantbruksstyrelsen* No. 5, 39 pp.(1935); *Chem. Zentr.* **1938**, II, 3438.—Different kinds of fish were used for these expts. and the sewage was dild. with filtered sea water. Acid sulfite waste liquors were much more injurious than alc. wastes. The latter show an instantaneous O demand, which, however, declines much more rapidly than that of the acid wastes. Fiber mixts. showed only a low O demand. In agreement with earlier findings, expts. with strong aeration showed that the fermentable carbohydrates promoted the development of sewage fungi. No injury to the fish gills by the cellulose fibers could be detected. The poisonous effects of the sulfate waste liquors (black liquors) were much greater than those of the sulfite wastes. This has been attributed by Ebeling and by Klingstedt to the presence of resin acids. Of the fish

tested the salmon was the most sensitive to such wastes. Tables and bibliography are given. W. A. Moore

The contamination of water by the waste liquors of sulfate pulp mills. Hilding Bergström and Sten Vallin. *Medd. Statens Undersökn.-Försöksanst. Sötvattensfisket, Kgl. Lantbruksstyrelsen* No. 13, 17 pp.(1937); *Chem. Zentr.* **1938, II,** 3438–9; cf. *C. A.* **33,** 6591[4].—A "poison unit" is introduced for comparison of results. The no. of poison units per l. is the degree of diln. (or diln. factor) required in order that young salmon can live in the resulting mixt. of sewage or waste and pure sea water for at least 5 days. The wash water from the green sludge was least poisonous; the condensates from boilers and diffusers most so, even after sepn. of the crude turpentine. The various S compds. in the condensate from the boiling, which even in small amts. imparts a disagreeable odor to the water and causes fish living in it to have an unpleasant taste, can be removed by effective sepn. of the condensates (during distn.). The greatest poisonous action was shown by the diffuser liquors and was due to the resin acids, fat acids and oleic acid contained in these wastes. The poisonous effects of the diffuser liquors can be essentially reduced by flocculation with acids. Tables and bibliography are given. W. A. Moore

Pressure-molded fiber products from cellulosic materials. L. K. Arnold. *Paper Ind. Paper World* **21,** 760–4 (1939).—Strong, practical cellar window sashes and fiber tubes were produced experimentally from waste newsprint and cornstalk and sulfite pulps. The sashes were waterproofed satisfactorily with paraffin. Warping was avoided by proper conditioning. Further tests in serviceability and practicability are being carried out. A. Papineau-Couture

A new trend in disk refiners. Bruce Armstrong. *Paper Trade J.* **109,** No. 25, 17(1939).—Attention is drawn to the present-day trend away from the double-disk type refiner (two rotating heads operating in opposite directions) toward the single-disk type refiner (one rotating head fitted with removable disks that operate against stationary removable disks attached to the refiner shell). The merits of the latter type are briefly outlined. A. Papineau-Couture

How to win the war on dirt. F. K. Becker. *Paper Trade J.* **109,** No. 18, 18–21(1939).—A brief discussion of the importance of the removal of dirt in pulp, showing the merits of the Bird screens, the Bird centrifiner and the Bird purifiner. A. Papineau-Couture

Activated decantation. Victor Perlmann. *Papier* **42,** 879–86(1939).—An explanation and discussion of activated decantation, which consists essentially in adding to the mixt. to be decanted an ingredient that accelerates sedimentation of the constituents to be sepd. A. Papineau-Couture

The wood-gas producer in the wood industry. H. List and J. Franzl. *Holz Roh u. Werkstoff* 2, 392–4(1939).—Results are given of the analysis of gas from a sawdust gas generator under different loads. R. H. Baechler

United States patents on papermaking. Third quarter, 1939. C. J. West. *Paper Trade J.* **109,** No. 17, 35–8 (1939). **Fourth quarter, 1939.** *Ibid.* **110,** No. 5, 27–30 (1940).—A list in numerical sequence of patents relating to pulp and paper making. A. Papineau-Couture

Utilization of farm wastes for paper and board making. E. C. Dryden, S. I. Aronovsky and T. D. Jarrell. *Paper Ind. Paper World* **21,** 972–7(1939).—A brief discussion and review of the use of cornstalks, straw, flax straw, bagasse, cotton by-products, oat hulls, peanut hulls, hemp and other agricultural wastes for the manuf. of paper and board. 94 references. A. Papineau-Couture

The uses of air in the paper industry. A. B. Davies. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20,** Pt. 1, 159–71(1939).—See *C. A.* **34,** 1847[9]. C. E. Curran

pH value and acidity; their significance in the paper industry. J. Grant. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20,** Pt. 1, 53–70(1939).—See *C. A.* **33,** 9635[1]. C. E. Curran

Applied statistics as an aid to paper investigations. P. H. Prior. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20,** Pt. 1, 81–98(1939).—See *C. A.* **33,** 9634[9]. C. E. Curran

PATRA and the paper industry. G. L. Riddell. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20,** Pt. 1, 109–37(1939).—See *C. A.* **33,** 9635[2]. C. E. C.

Plastics in papermaking. H. W. Rowell. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20,** Pt. 1, 143–51(1939); cf. *C. A.* **33,** 9636[5].—Use of plastics in papermaking equipment is discussed. C. E. Curran

Investigations on the calendering of paper. W. Brecht. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20,** Pt. 1, 11–39; *Paper-Maker* **97,** TS41–52(1939).—A résumé of calendering expts. previously reported by Brecht and Steinbock, *C. A.* **33,** 6591[9]. C. E. Curran

Proposed apparatus for determining the "wet-strength" of paper. O. E. Sylwan. *Svensk Papperstidn.* **42,** 507–8 (1939).—A satisfactory instrument for detg. the "wet-strength" of paper must be simple, easily taken care of, reliable, sensitive, and give a sharp reading. S. has devised an electrometric app. consisting of a bath with const. level of a 0.25% NaCl soln., appropriate elec. contacts and instruments to measure and record the wetting of the paper. The time required for complete penetration of the paper sample by water as measured by a chronometer included in the elec. circuit is a measure of the "wet-strength" of the sample. Wilhelm Segerblom

Papermaking properties of holocellulose. Harold H. Houtz and Ervin F. Kurth. *Paper Trade J.* **109,** No. 24, 38–41(1939).—Material approximating holocellulose (**A**) was prepd. by a method adapted from the quant. procedure developed by Van Beckum and Ritter (*C. A.* **31,** 6458[8]). A 2nd fraction (**B**) was obtained by extg. part of **A** with 0.5% $(NH_4)_2C_2O_4$ soln. at 90°; chem. analysis indicated that a small amt. of the pentosans and polyuronides had been removed. A 3rd fraction (**C**) was obtained by overchlorination and hydrolysis during the prepn.; analysis showed that more than half the pentosans had been removed and that the β-cellulose content had been considerably increased. A 4th fraction (**D**) was obtained by extg. part of **C** with 17.5% NaOH, resulting in a pulp with α-cellulose content comparable to that of com. alpha pulp and low in hemicellulosic materials. The rate of change of freeness when these materials were processed in a lab. beater indicated that the less-resistant forms of cellulose (β- and γ-celluloses), pentosans and polyuronides have an important influence on hydration. The phys. tests indicated that good fiber-fiber bonding and high initial individual fiber strength were obtained with **A** and **B**; good bonding was also obtained with **C**, but the fiber strength had been decreased by degradation of the cellulose or by breaking up of the fiber bundles; **D**, which was low in hemicellulose, was very resistant to beating and developed very poor strength characteristics. **A, B** and **C** aged much more rapidly than **D**, the aging of **C** being the most rapid. The results are believed definitely to substantiate the chem. theory of beating with the formation of gelatinous hydrate. It is evident that hemicellulosic materials play an important part in the development of this gelatinous hydrate, although it would be difficult to deduce just which constituent is definitely responsible for this action. The less-resistant cellulosic materials seem to play a very important part in this respect, while the polyuronides and the pentosans also exert a considerable effect. Aging appears to be accelerated by the presence of hemicellulosic materials, the degraded cellulose having the greatest effect. Probably the most important result of the work was the production of a pulp which not only could be beaten to a glassine stock in a very short time, but also developed some remarkable strength characteristics. The data show the desirability of conducting the cooking process, in the production of pulps to be used for highly hydrated papers, in such a manner that as much as possible of the hemicellulosic material is retained. A. Papineau-Couture

Instrumentation studies. XXXIV. Penetration of papers by liquids and solutions. 1. General discussion of the phenomena. Staff of the Institute of Paper Chem-

istry. *Paper Trade J.* **110**, No. 4, 44–50(1940); cf. *C. A.* **33**, 9638⁹.—Current theoretical descriptions of the flow of liquids and solns. through such porous and fibrous materials as paper are summarized. Tests employed to evaluate paper for various uses involving penetration by liquids and solns. are discussed in the light of these theories. A. Papineau-Couture

The fluorescence size test, an improved method and a new instrument for measuring the water resistance of paper. J. A. Van den Akker, Philip Nolan, A. C. Dreshfield and H. F. Heller. *Paper Trade J.* **109**, No. 21, 33–42(1939).—Expts. leading to the development of a new method for measuring the water resistance of paper are described. The transudation of water is detected by a fluorescent indicator which exhibits strongly a so-called "concn. effect." This characteristic of the fluorescent indicator distinguishes it from other indicators of transudation of water, mainly as regards error due to water vapor permeability of the paper under test. Data and observations are given which indicate that transudation times obtained with the fluorescent indicator are subject to negligible error due to water vapor. The development of an objective method involving photoelec. recording of the fluorescence intensity is given, and data on the influence of a no. of variables are presented. With the photoelec. equipment, it was found that the typical probable error in the mean of 10 observations was 1.5%. A. Papineau-Couture

The Neenah expansimeter. A method for measuring the expansion or contraction of papers caused by change in relative humidity. J. A. Van den Akker. *Paper Trade J.* **109**, No. 22, 105–6(1939).—A sensitive spirit level vial is supported at one end from the lower end of the test specimen (cut in the form of a long strip) and at the other end by a pair of sharply pointed wire feet. The test specimen is supported at its upper end by a simple micrometer arrangement; the lower end of the strip is maintained at const. elevation by means of the spirit level vial, and changes in length are measured at the upper end by means of the micrometer. The pitch of the micrometer screw and the length of specimen are chosen so that the percentage change in length may be read directly from the micrometer dial. A. Papineau-Couture

The Meyers consistency controller and volumetric stock meter. S. E. Meyers. *Paper Trade J.* **110**, No. 5, 13–16(1940).—A description of the latest model of this instrument, which is an improvement on earlier models, together with a discussion of its merits. A. P.-C.

Lubrication, with special reference to paper-mill machinery. D. T. McHutchison. *Proc. Tech. Sect., Paper Makers' Assoc. Gt. Brit. & Ireland* **20**, Pt. 1, 173–82 (1939). C. E. Curran

A practical alum test. L. H. Donnally. *Paper Ind. Paper World* **21**, 1083–4(1940).—Prep. a 0.1% soln. of papermakers' alum ($Al_2(SO_4)_3.18H_2O$); to 2 drops of this soln. on a spot plate add 2 drops of a soln. contg. 100 g. $AcONa.3H_2O$ and 30 cc. glacial AcOH per l., and then 1 drop of 0.05% soln. of hematein in 95% alc., and note the deep purplish coloration. Dil. the standard alum soln. with an equal vol. of mill water and repeat the test; continue making the test after successive dilns. till no purplish coloration appears in 1 min. Run the same test on white water or any other alum-contg. soln. to be tested, and from the resp. dilns. at which no coloration appears in 1 min. in the standard and sample, calc. the alum content of the latter. A. Papineau-Couture

Colorimetry for paper. W. E. Rand. *Pulp Paper Mag. Can.* **41**, 13–18(1940).—A discussion explaining and emphasizing the advantages of numerical over visual measurements of color. A. Papineau-Couture

Some of the paper problems in multicolor offset printing. Charles G. Weber. *Paper Trade J.* **109**, No. 16, 29–33 (1939).—A discussion of the causes of register troubles. The soln. of the problem lies in the prepn. and conditioning of papers. To be properly prepd. for multicolor printing, paper must be in equil., with relative humidity about 5–8% above the pressroom condition. A. Papineau-Couture

The fundamental scattering and absorption coefficients of dyed hand sheets. Wm. J. Foote. *Paper Trade J.* **109**, No. 25, 31[c]–8(1939); cf. *C. A.* **33**, 4029⁸.—The direct proportionality of the concn. of dye solns. to the log of their light transmission holds accurately for the range within which it was used to det. dye retention, but does not hold for high concns. An equation was developed for calcg. the retention of each dye component in a hand sheet dyed with 2 dyes of the same class. For basic dyes, the exptl. data obtained indicated that, in most cases, neither component interfered with the absorption of the other in the range studied; differences in retention due to this interference were less than 4%. The fundamental assumptions made in extending the theory of Kubelka and Munk concerning the diffuse reflection of light from homogeneous media to the more complex systems contg. pulp plus 1 or more dye components were investigated with the following results: (1) Pulp and dye do not in general absorb light independently of each other, since the absorption coeff. per g. of retained dye varies with different pulps. (2) The scattering coeff. of a dyed hand sheet is practically independent of the dye for dyeings up to 1 lb. per 1000 lb. of stock, but it decreases appreciably for heavier dyeings. (3) The absorption coeff. of a mixt. is generally less than the sum of the resp. coeffs. of the components and may be taken as equal to the sum only for purposes of approximation. The assumption that the absorption coeff. of dye in a hand sheet is directly proportional to the amt. of dye present on the fiber is in error; the proportionality is approx. a straight-line function in the range up to 3-lb. dyeings, but deviates strongly with heavier-wt. dyeings. The empirical relationship is presented in graphic and tabular forms. A. Papineau-Couture

Coating paper on the paper machine. G. K. Dickerman. *Paper Mill* **61**, 15–19(Dec. 31, 1938).—The Massey process is described. B. C. P. A.

Paper-machine coating processes. Peter J. Massey. *Tech. Assoc. Papers* **22**, 213–16(1939); *Paper Trade J.* **109**, No. 16, 34–7(1939).—A review of the existing processes relating to coating of printing papers on the paper machine, commenting on the principle involved and mentioning printing developments. Consideration is given to costs involved and the nature of the coating mix. A. Papineau-Couture

The Ortho-Krome process of coating paper. Albert B Hurley. *Tech. Assoc. Papers* **22**, 216–19(1939); *Paper Trade J.* **109**, No. 16, 37–40(1939).—A description of a coating process utilizing the printing principle to reduce glare from the paper surface. A. Papineau-Couture

Antitarnish paper. Herbert W. Rowe and Otto Kress. *Paper Trade J.* **110**, No. 2, 33–6(1940).—The presence of H_2S is the most important factor in the tarnishing of Ag. Cu acetate and Cd acetate are the most effective in protecting Ag from tarnishing. Furthermore, these salts impregnated in paper absorb H_2S preferentially to Ag wrapped in plain paper. Cu acetate is preferable to Cd acetate because of the high cost of the latter. Antitarnish kraft papers impregnated with 2.3% Cu acetate are at least 10–20 times more effective in preventing the tarnishing of silverware by H_2S than are the unimpregnated antitarnish kraft papers. Paper contg. 1.4% CuO (added as $Cu(OH)_2$ to the beater furnish) is at least 10 times more effective than the same paper without CuO, from the standpoint of its ability to prevent the tarnishing of Ag in an atm. of H_2S. Impregnation does not impair the phys. characteristics of the paper. A. Papineau-Couture

Fundamentals of glassine transparency. III. Sheet properties. Dan B. Wicker. *Paper Trade J.* **110**, No. 1, 36–42(1940); cf. *C. A.* **33**, 859⁹.—Surface characteristics of a sheet are important factors in detg. transparency, but not necessarily the limiting factors so far as the results of current com. practice are concerned. The presence of air voids within the sheet is the single factor which has the greatest deleterious effect on transparent qualities. The presence of mineral constituents in proportions of less than 1% has a definite but minor effect on quality. There is a lack of evidence to indicate that the max. attainable transparency of glassine paper is seriously limited by the birefringent properties of cellulose fibers. The addn. of a small

amt. of dye to the furnish for glassine paper seems to have a rather marked beneficial effect on transparency. A photomicrographic study indicated that the residual effect of the contour of the paper machine wire on the properties of the glassine sheet is the greatest contributory factor toward producing undesirable air voids. The practical interpretation of the exptl. results is discussed.
A. Papineau-Couture

Moisture-vapor proofness of wrapping materials used on frozen foods. Clarence W. DuBois and Donald K. Tressler. *Paper Trade J.* **109**, No. 20, 15–18(1939).—On the assumption that a paper or other wrapping material adequately protects meat and other foods from dessication if, at 5°F., it transmits not more than 3 g. of moisture vapor per sq. m. per 24 hrs., and if in addn. the material is not stained by blood or by grease and does not become brittle at low temp. or impart a flavor to the food, 13 of 25 materials tested were considered satisfactory for use in packaging foods for storage in refrigeration lockers.
A. Papineau-Couture

Effect of filler brightness on lined board brightness. W. R. Willets, R. T. Bingham and L. H. Eriksen. *Paper Trade J.* **109**, No. 23, 42–4(1939); cf. *C. A.* **33**, 9638[1].—The brightness of a lined board is shown experimentally to be dependent on the opacity and brightness of the liner, and on the brightness of the underlying filler. If the opacity and brightness of the liner are const., the brightness of the filler dets. the brightness of the board. If the brightness of the filler is const., the opacity and brightness of the liner dets. the brightness of the board. It is probably more feasible to increase board brightness by increasing the opacity and brightness of the liner than by increasing the brightness of the filler. It is possible to cover a filler of low brightness and secure good ultimate board brightness, even with light-weight liners, if the liner is pigmented with TiO_2.

Obtaining cellulose from wood, etc. Henry Dreyfus. U. S. 2,183,643, Dec. 19. In obtaining cellulose, suitable for manuf. of paper or cellulose derivs., from wood or other lignin-contg. cellulosic materials by heating with HNO_3 in amt. sufficient to convert all the lignin into alkali-sol. oxidation products and subsequently washing the material with alkali to dissolve the alkali-sol. products, the HNO_3 is used in admixt. with at least 10 times the wt. of the materials of an aq. lower aliphatic acid such as aq. HOAc of a concn. between 15% and 75%.

Centrifuge for acetylating cellulose or for other chemical reactions. Henri Argant, Henry Chanay and Georges Robatel (to Ateliers Robatel & Buffaud and Compagnie nationale de matières colorantes et manufactures de produits chimiques du Nord réunies, établissements Kuhlmann). U. S. 2,184,038, Dec. 19. Various structural, mech. and operative details.

Cellulose ethers. Horace F. Oxley, Edward B. Thomas and John Downing (to Celanese Corp. of America). U. S. 2,184,564, Dec. 26. A process of the manuf. of cellulose ethers contg. hydroxyalkyl or carboxyalkyl groups, such as cellulose hydroxyethyl ethers, involves impregnating cellulosic material such as wood pulp with an aq. soln. of a base such as NaOH in a concn. of 10–16%, subjecting the impregnated material to treatment under reduced pressure to remove water until the concn. of the base in the aq. soln. present is about 25–35%, and then etherifying with a reagent such as ethylene oxide.

Mixed esters of cellulose. Loring W. Blanchard, Jr., and Carlton L. Crane (to Eastman Kodak Co.). U. S. 2,183,982, Dec. 19. A mixed cellulose ester contg. dicarboxylic acid radicals such as those of phthalic or succinic acid and lower aliphatic acid radicals such as those of HOAc is prepd. by the reaction upon a lower aliphatic acid ester of cellulose of a bath contg. a dicarboxylic acid such as phthalic or succinic acid or its anhydride, an inert solvent for the mixed ester produced, such as Me Et ketone and 2–50% of water based on the wt. of cellulose ester initially present and addnl. to the 2–7% of moisture usually present in a lower aliphatic ester of cellulose (the bath being free from esterification catalysts and tertiary org. bases). Cf. *C. A.* **34**, 623[1].

Compositions of cellulose derivatives such as cellulose acetate. Harold A. Auden, Hanns P. Staudinger and Henry M. Hutchinson (to Distillers Co. Ltd.). U. S. 2,183,317, Dec. 12. A compn. suitable for films is formed of a cellulose ester of an org. acid, such as cellulose acetate, and an acetal contg. 2 O atoms and at least 7 C atoms and resulting from the condensation of an aldehyde with a monohydric alc. contg. a single O atom or a halogen substitution product of such an alc. Several examples are given.

Converting waste regenerated cellulose to cellulose xanthate. Giuseppe Donagemma and Piero Donagemma (to "Snia-Viscosa" (Società nazionale industria applicazioni viscosa)). U. S. 2,184,586, Dec. 26. A process of mfg. artificial textile fibers involves washing in running water and drying waste threads collected in the manuf. of rayon, treating the waste rayon threads in a NaOH bath at 16 to 17.5% for about 1.0–1.5 hr., wringing the waste threads to expel the excess of NaOH, disintegrating the alk. cellulose for about 2 hrs. at a temp. of 18 to 29°, allowing the cellulose to ripen for 25 to 35 hrs. at the temp., treating the ripened cellulose in a bath contg. about 7 l. CS_2 to 100 kg. alk. cellulose for about 1.5–2 hrs. while increasing the temp. to 22–24°, and treating the resulting xanthogenate for about 3 hrs. in mixing machines contg. 0.40 to 0.50% NaOH per 130 l. of water to 100 kg. alk. sulfuretted cellulose to obtain a cellulose suitable for spinning.

Marking cellulosic products such as sausage casings. Roger N. Wallach and Willard L. Morgan (to Sylvania Industrial Corp.). U. S. 2,183,948, Dec. 19. A process of mfg. a marked cellulosic material comprises applying an ink in the form of an indicium to a body, such as a sausage casing, composed of a cellulose deriv., such as viscose in the gel state (the ink having a water-miscible vehicle such as "Cellosolve" which is a solvent for the cellulose deriv.), and converting the deriv. into a cellulose hydrate.

Apparatus for the production of film or foil webs from solutions of cellulose or cellulose derivatives. Emil Czapek (to Guaranty Trust Co. of N. Y.). U. S. 2,183,255, Dec. 12. Various structural, mech. and operative details.

Spinning centrifuge suitable for use in rayon manufacture. Otto Bochmann (to American Bemberg Corp.). U. S. reissue 21,290, Dec. 12. A reissue of original patent No. 1,992,602.

Apparatus for making articles of die-molded and die-dried fibrous pulps. Walter H. Randall and Fred C. Harper (to Canal National Bank of Portland, Me., as trustee). U. S. 2,183,869, Dec. 19. Various structural, mech. and operative details.

Papermaking apparatus. Charles W. Howard (to

Black-Clawson Co.). U. S. 2,184,189, Dec. 19. Various structural, mech. and operative details.

Softening agents for paper, textile fabrics and leather. Herbert A. Lubs and Luther B. Arnold, Jr. (to E. I. du Pont de Nemours & Co.). U. S. 2,183,721, Dec. 19. An aq. treating medium is used contg. Na sulfamate or other sulfamate of the general formula H_2NSO_2X in which X represents H or a salt-forming radical, together with a long-chain alc. sulfate ester salt contg. 8 or more C atoms such as Na cetyl sulfate.

Rendering paper soft and flexible. Francis De Witt (to Pervel Corp.). U. S. 2,183,711, Dec. 19. App. is described, and a process of treating paper to render it soft and flexible which involves applying to the paper a soln. contg. water about 72–80 fl. oz. and about 28 fl. oz. of glycesol or other water-sol., stable polyhydroxy alc. or an ether or ester of such alc. having a b. p. above that of water, together with about 14–16 oz. of finely divided water-insol. inorg. filler such as Mg silicate capable of adsorbing the paper-softening agent, and removing the water from the paper.

Sized paper. Joseph A. Warren (to S. D. Warren Co.). U. S. 2,183,858, Dec. 19. An alk.-filled, uncoated paper is surface-sized with a size consisting essentially of soybean protein.

Basic sulfamate of quadrivalent titanium. Charles W. J. Wende (to E. I. du Pont de Nemours & Co.). U. S. 2,184,538, Dec. 26. A basic salt of quadrivalent Ti and sulfamic acid suitable for use in *treating paper* or *leather* or in *prepg. pigments* is formed by the reaction in aq. soln. of $TiCl_4$ and a sulfamate such as that of Pb the cation of which forms an insol. chloride.

Grease-proof paper. Warner J. Merrill (to E. I. du Pont de Nemours & Co.). U. S. 2,184,312, Dec. 26. A process for prepg. grease-proof paper suitable for use in packaging foods, etc., comprises mixing paper pulp before sheet formation with size contg. deacetylated chitin in an aq. medium, pptg. the deacetylated chitin on the paper pulp, forming the pulp into a sheet, drying and then swelling the pptd. deacetylated chitin by surface sizing the paper with size soln. contg. deacetylated chitin in an aq. medium.

Grease-proof paper suitable for wrapping foods, etc. Louis L. Larson (to E. I. du Pont de Nemours & Co.). U. S. 2,184,307, Dec. 26. A paper-manufg. process is employed which involves mixing paper pulp with size soln. contg. deacetylated chitin as the film-former, pptg the film-former on the paper pulp, applying to the sized fibers within the primary papermaking operation before drying the sheet formed from the sized fibers an aq. soln. of an acid swelling agent which swells the pptd. film-former without parchmentizing the fibers, allowing the swelling agent to react until the film-former is in a highly swollen condition, and before drying the sheet stopping the action of the swelling agent while the pptd. film-former is in a highly swollen state but before it has been dissolved to the sol state.

Carbon paper. Josef Burgmer. U. S. 2,183,474, Dec. 12. Various details of app. and operation.

Carbon manifolding paper. Allan K. Ohashi. U. S. 2,183,580, Dec. 19. A process for making manifold sheets comprises coating and impregnating a sheet of paper on and through one of its surfaces with a suitable normally solid carbon-contg. color compn. and then impregnating the sheet through its other surface with a plasticized cellulose nitrate compn. which solidifies on standing, to form a highly flexible impregnation.

Reclaiming constituents of waxed paper "broke." Arnold M. Hill (to National Oil Products Co.). U. S. 2,183,259, Dec. 12. The "broke" is disintegrated in water heated to a temp. sufficiently high to melt the wax constituent and the wax is emulsified with a mineral oil sulfonate and a sulfonated animal or vegetable oil, fat or wax, such as sulfonated sperm oil.

24—EXPLOSIVES AND EXPLOSIONS

C. G. STORM

Detonation limits of gaseous mixtures. P. Laffitte. *IIme Congr. mondial pétrole* **3**, Sect. 4, 738–43(1937)(in French).—L. defines the limit of detonation so as to include the limits of explosivity but to exclude therefrom the limits of inflammability. After a brief review of the work of various authors on the speed of propagation of the explosive wave a method of photographic recording is outlined which is used not only to mark off sharply the limits of detonation but to measure the speed of progagation of the explosive wave in regions where the explosive phenomenon is very little or not at all photogenic. Detonation limits have been studied for the following mixts.: H_2–O_2, H_2-air, CO–O_2, NH_3–O_2, C_3H_8–O_2, iso-C_4H_{10}–O_2, C_2H_2–O_2 and C_2H_2-air, Et_2O–O_2 and Et_2O-air. All the mixts. produced explosive waves propagating in a helicoidal trajectory. 17 references. E. J. Mahler

Explosion limits of gaseous mixtures. VI. Influence of the temperature on the limits of explosion of hydrogen-air mixtures. A. S. Sokolik. *Acta Physicochim. U.R.S.S.* **11**, 239–50(1939)(in French); cf. *C. A.* **32**, 5630⁸.—The lower explosion limit for H_2-air mixts. is 21% H_2 at 20–150°, decreasing to 18% at 400°. The water formed as a product of reaction retards the formation of the explosive wave and the ignition of the mixt. The force of the explosion wave is decreased to approx. half by passage through a region of temp. drop from 300 to 20°. F. H. Rathmann

The inflammable ranges of ethylene-air mixtures. J. S. Forsyth and D. T. A. Townend. *Engineering* **149**, 127(1940).—At atm. pressure, the inflammability range of C_2H_4-air mixts. extended from 3.1 to 15.5%. Between 27 and 40 cm. of Hg, a range of mixts. was found through which flame could not be propagated, although mixts. of higher or lower C_2H_4 content were inflammable. This range is assocd. with a mechanism giving rise to C deposition. Between 11.2 and 13 cm. of Hg a similar but smaller range was found. The mixts. ignitable at the lowest pressures are those exhibiting the greatest flame speed. Joseph H. Wells

A method for the analysis of technical trinitroxylene (xylyl). Ya. I. Leĭtman. *Trudy LKKhTI* **1939**, No. 7, 127–41; *Khim. Referat. Zhur.* **2**, No. 5, 66–7(1939).—A review of existing methods for the analysis of trinitro-*p*-xylene and nitro derivs. of ethylbenzene. For the detn of "xylyl oil," consisting mainly of the di- and the trinitro derivs. of *o*-xylene and ethylbenzene, dry at 80°, wash 10 g. on a Gooch filter first with hot water (0.75–1 l.), then with alc. to remove the oil drops. The decrease in wt. of the sample gives the content of "xylyl oil." In the product (freed from oil) det. the temp. of the beginning of the crystn. and the eutectic temp. The contents of trinitro-*p*-xylene and trinitro-*m*-xylene are found from the fusion diagram of the binary mixts. of these substances. The content of the nitro derivs. of ethylbenzene is detd by the sulfite method. Heat 10 g. of sample on a water bath with 120–30 cc. of a 5% soln. of Na_2SO_3, filter the insol. residue consisting mainly of a mixt. of the nitro derivs. of ethylbenzene and trinitro-*m*-xylene, dry the residue and det. the content of the nitro derivs. of ethylbenzene from the loss of wt. W. R. Henn

Explosion during the commercial extraction of cacao shells. Kattenstroth. *Feuerschutz* **20**, 6–8(1940).—The explosion occurred when, because of improper manipulation of the extn. app., the pressure of the extg. medium, C_2HCl_3, increased to 6–8 atm. in a machine which had been fitted with a defective cover. Leopold Scheflan

Liquid fires and how to fight them. H. H. Dierksen. *Marine News* **26**, No. 9, 49–50(1940).—A description of methods of extinguishing fires on shipboard. L. S.

Experiments on the protection of wood against fire by

the use of asbestos cement. Otto Drögsler. *Feuerschutz* **19**, 158–9(1939); **20**, 9–10(1940).—Fire tests in a four-room building are described. The resistance to fires of wood is increased by the use of asbestos-cement plates of a thickness of 4–5 mm. Leopold Scheflan

Waterproof package for explosives such as those for blasting. Floyd J. Rape (to American Cyanamid & Chemical Corp.). U. S. 2,184,166, Dec. 19. A container is used formed of at least 2 layers of material such as paper laminated with an intervening layer of moisture-impervious material such as a thermoplastic compn. contg. rubber and paraffin wax.

Apparatus for producing fire-extinguishing foam. Clyde M. Hamblin. U. S. 2,183,561, Dec. 19. Various structural, mech. and operative details.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Preparation of Indigosol Orange HR. M. K. Bezzubets and V. S. Rozina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 500–3(1939).—The theory and practice of the synthesis of the dye by the methods of Ger. pats. 424,981 and 563,958 (cf. Brit. pat. 247,787, *C. A.* **21**, 654) are discussed and a modified procedure of prepn. is suggested. C. B. 3

Attempts to prepare sulfur dyes from rosin. R. Kishore and K. C. Mukherji. *J. Sci. Tech., India* **4**, 23–6(1938). – Abietic acid, m. 154–5°, was nitrated by 3 different methods (Dubourg, *C. A.* **22**, 593; Goldblatt, Lowy and Burnett, *C. A.* **24**, 3019) with HNO_3 of sp. gr. 1.42 and as a third component CCl_4, H_2SO_4 sp. gr. 1.84, and 94% EtOH, resp. The products were not cryst. and decomp. at about 142°, 170° and 130°. Analysis for N showed 6.87% and 7.20% for the products from the first 2 nitration methods. They were apparently dinitro compds. Brown dyes differing only in shade were obtained from 10 g. nitro compd., 15 g. S, 42 g. Na_2S (cryst.), 50 cc. H_2O by refluxing 15 hrs. The dye was pptd. by blowing in air. Previously scoured cotton twill was dyed in a bath contg. 0.31 g. dye, 0.62 g. Na_2S (cryst.), 0.08 g. Na_2CO_3 and 20 cc. H_2O. The dyed cloth was treated with 25 cc. of soln. contg. 1% $K_2Cr_2O_7$, 1% $CuSO_4$ and 1.5% AcOH for 0.5 hr. at 50–5°. The light brownish shades obtained were not deep enough to be satisfactory but may prove useful for hand-spun yarn. Amino compds. were prepd. by reduction of the nitro compds. with Zn and HCl and used to make S dyes. The dyes were not very different from those obtained from the nitro compds. 4

A. J. Stirton

Analysis of naphthols of the AS group. K. D. Shcherbachev. *Org. Chem. Ind.* (U. S. S. R.) **6**, 249–52(1939). – The volumetric detn. is based on the soly. of arylides of 2-hydroxy-3-naphthoic acid (I) in pyridine (II) and the easy diazotization of the solns. with PhN_2Cl. In the presence of excess II the pptn. of the azo dye and naphthol during the titration is prevented. The usual admixts. of free I in com. azo colors can be extd. with aq. $NaHCO_3$ and the insol. arylides of I are then detd. in the filter cake. More accurate results can be obtained by titrating an arylide in 2 sep. weighings with and without the preliminary sepn. of I. If desired, I can be detd. in the $NaHCO_3$ filtrate by titration with PhN_2Cl. Moisten a 0.3–0.4-g. sample with 1–2 ml. alc. and dissolve in 5–7 ml. of hot *N* NaOH. Dil. to 50 ml. with water, add 1–2 drops of phenolphthalein and pass CO_2 until the soln. is decolorized. Filter on a Büchner funnel, wash the ppt. with water, transfer it with the filter into a beaker, dissolve in about 50 ml. II (b. 120–40°) (depending on the soly. of the I arylide) and titrate at 5° with 0.05 *N* PhN_2Cl until the drop test with H acid gives a permanent color reaction (5 min.). Dissolve a 0.3–0.4-g. sample in 50 ml. II and titrate directly with PhN_2Cl as above. Calc. the I arylide from the difference of the 2 detns. To det. the primary amines in I arylides, triturate a 5-g. sample with 5 ml. of concd. HCl and 50 ml. H_2O, add 1 g. KBr and titrate with 0.1 *N* $NaNO_2$ at 15–20°. Chas. Blanc 5 6

The use of sodium hyposulfite in the quantitative splitting of azo dyes. Victor I. Zaraus. *Bol. soc. quim. Peru* **5**, 124–33(1939).—A quant. method for the splitting of azo dyes based on the following reactions is presented: $4NaHSO_3 + Zn \rightarrow ZnSO_3 + Na_2SO_3 + 2H_2O + 2Na_2S_2O_4$; $2Na_2S_2O_4 + 8H_2O + RN{=}NR' \rightarrow 4NaHSO_4 + 3RNH_2 + 3R'NH_2$. 0.1 to 0.5 g. of the dye is shaken up with 10 cc. of a standard $NaHSO_3$ soln. and 3 g. of Zn. After standing 5 min. 1 cc. of glacial acetic acid is added and after 10 min. more 5 g. of $NaHCO_3$ and the soln. titrated with standard iodine soln. Results using methyl red and Congo red are given and a total of 6 dyes have been tried using this method. Oden E. Sheppard 7

Investigation of mordants on fibers as a means of identifying the dyes used. P. Baffroy. *Teintex* **5**, 9–14 (1940).—Animal fibers are burned and then heated with HNO_3 or NH_4NO_3 to complete the oxidation. A white residue indicates presence of Al, Ca, Sn, Sb, Si, Ba, clay, W or Ti. A brown or yellow-brown ash shows the presence of Fe alone or mixed with some white ash. A brown or brown-black residue indicates Cu, Mn, Ni, Co or Cr. A gray-green ash indicates Cr. Methods of testing for these elements are included. Saverio Zuffanti 8

Fast greens on woolen cloth. Raffaele Sansone. *Textile Colorist* **61**, 674–6, 708(1939).—Procedures and formulas are given for dyeing with Indigosol Green 1B, Alizarinecyanine greens, Erio Green B, Palatine Green GN, Anthranlan Green GG and Metachrome Green WL; and for printing with Fast Palatine Green BGN, Alizarinecyanine GT, and the Indigosols. R. K. W. 9

Use of continuous processes in dye industry. N. N. Vorozhtsov, Jr. *Org. Chem. Ind.* (U. S. S. R.) **6**, 422–3 (1939).—The review of known processes for the continuous production of dye intermediates includes the production of phenols, naphthols and their derivs. from the corresponding chlorides and sulfonic acids by decompn. with aq. alkalies, obtaining of amines from PhCl and $C_{10}H_7Cl$ with NH_4OH and reduction of nitro compds. with H in the presence of catalysts. Ten references. Chas. Blanc 10

Note on the absorption of substantive dyes by oxycelluloses of the acidic type. S. M. Neale and W. A. Stringfellow. *J. Soc. Dyers Colourists* **56**, 17–18(1940).—The reduction of affinity consequent upon oxidation of cellulose has been examd. quantitatively and a possible mechanism is suggested. The remarkable effect of relatively mild oxidation on the dye absorption is shown in a curve in which the amt. of Sky Blue FF absorbed at equil. under the same conditions by various oxycelluloses is plotted against the COOH-group content. In the acidic type of oxycellulose COOH anions form an integral part of the solid structure and retain them near their corresponding cations. The greater the no. of sulfonic groups in the dye, the greater is the decrease in absorption for a given oxycellulose compared with the absorption for unoxidized cotton. The supposition is confirmed by recorded results on dyeings of alk. hypobromite oxycelluloses by 2 groups of dyes contg. 2- and 4-sulfonic groups, resp. The actual values of absorption on standard cotton are lower for the group of dyes contg. sulfonic groups in the mol. W. H. Boynton 11

Indanthrene dyeing of cotton in the "Proletarkaja Pobeda." Ryabtsev and Drushinin. *Sherstyanoe Delo* **17**, No. 5, 51–6(1938); *Chem. Zentr.* **1938**, II, 3462.—Cotton was uniformly dyed by use of a bath of the following compn.: Indanthrene Blue BO in paste 9.0%, Sulfur Black Tsch F 5.5%, hyposulfite (85%) 13.0%, NaOH (40°Bé.) 18.0%, alizarin oil 5.5% and glue 2.7%. Incomplete washing out of the alizarin oil is suggested as the cause of large amts. of waste during the spinning of dyed cotton. W. A. Moore 12

Equalizing and penetration in the dyeing of textiles.

G. Schwen. *Melliand-Textilber.* **21**, 17–28(1940).—Improper prepn. of the goods is inimical to even dyeing as is shown by colored pictures illustrating dyeing defects caused by the local action (1) of alkali, acid, light and pptd. lime soaps on wool and (2) of uneven bucking, acids and oxidation agents (bleaches) on cotton and (3) of oil residues on rayon. Other colored pictures show the beneficial effects, on evenness of dyeing, of dyeing at higher temps., prolonged boiling in the dye bath, choice of proper pH depending on the dyestuff being used, use of surface-active agents to ensure even wetting of the goods and use of agents to prevent the dyestuff being taken up too rapidly by the fiber. The latter agents are (*a*) those having affinity for the fiber (e. g., Igepon T or Gardinol with wool) and (*b*) those having affinity for the dyestuff (e. g., certain highly oxygenated compds. such as Palatine Fast Salt O with Palatine Fast Blue GGN or Peregal O with Chicago Blue 6B). J. W. Perry

The dyeing of buttons. Oskar Giessler. *Klepzig's Textil-Z.* **43**, 142(1940).—Artificial horn buttons (manufd. from casein, HCHO and fillers) are dyed usually without any preliminary prepn. in a soln. highly acid with H_2SO_4 in the absence of Glauber's salt; in some cases AcOH may be used. Sp. directions are given. Leopold Scheflan

Fading of dyed textiles by radiant energy. Matthew Luckiesh and A. Hadley Taylor. *Illum. Eng.* **35**, 169–72 (1940).—Forty specimens of dyed cotton, wool and silk of grades 0 to 4 (appreciable fading in sunlight after 6, 12, 24, 48 and 96 hrs.) were exposed to fluorescent "daylight" lamps and to 75-watt W lamps. In general, W lamps cause more rapid fading of blue, violet and purple specimens; and the fluorescent lamps, slightly more rapid fading of pink, yellow, orange and red specimens, regardless of whether the cloth is cotton, wool or silk. No dyed synthetic textiles were tested. Expts. are still in progress. C. G. F.

Newer ideas in textile chemistry. T. W. Whattam. *Can. Textile J.* **57**, No. 4, 34, 36(1940).—A discussion of the properties of surface-active agents designed for more efficient textile processing with particular reference to faster wetting-out, adsorption and wetting-out by orientation. Leopold Scheflan

Textiles from central Africa. Jos. Franz. *Klepzig's Textil-Z.* **43**, 133–7(1940).—An illustrated description of antiquated and modern methods of the manuf. and chem. treatment of textiles. Leopold Scheflan

Researches on hemp. Giuseppe Cotroneo. *Rend. accad. sci.* (Napoli) **8**, 63–75(1938).—In Acerra (Naples) 4 parcels of ground were seeded on April 11 in 4 different ways and fertilized with 3 different fertilizing compns. On May 25, June 4, June 25, July 20 and Sept. 9, samples were taken from 7700 plants that were sufficiently mature for industrial use. Cellulose, lignin and ash contents, resp., were: May 25, 43.3, 1.7, 15.4; July 20, 65.7, 2.2, 4.4; and Sept. 9, 67.3, 3.2 and 4.1%. The fibers were macerated by Rossi's method (biological maceration) (*C. A.* **22**, 1241) and the av. cellulose content increased from 65 to 85%, the lignin decreased from 2.3 to 2% and the ash decreased from 4.7 to 0.9%. The different fertilizing mixtures had little effect. The male hemp shows a less advanced state of ripening. V. S. de Marchi

The new synthetic polyamide fibers. Maria Broggi. *Chimica e industria* (Italy) **22**, 10–13(1940).—The story of nylon. Nylon will soon be produced in Italy under license. A. W. Contieri

X-ray study of the orientation of artificial fiber. I. V. A. Kargin and N. V. Mikhailov. *Acta Physicochim. U. R. S. S.* **11**, 343–60(1939) (in English).—Exptl. data on the strength and percentage elongation of wet and dry samples of cuprammonium rayon and viscose rayon variously prepd. and treated are given. In contrast to the theory of Mark and Meyer (cf. *C. A.* **23**, 1263), K. and M. hold, on the basis of these data, that the true equil. state is one in which the chain aggregates are in a more or less disordered arrangement, and that the elongation-approach to a true crystal is an unstable state. Highly swollen gelatin contg. only 2% α-cellulose shows 2 to 3-fold elongation and, like rubber, almost instantaneous shrinking. F. H. Rathmann

Linen threads and their manufacture. Clifford Carter. *Ind. Fibres Rev.* **4**, 104–8, 126, 128–9, 145–8(1939).—A detailed discussion of chem. and mech. treatments. Leopold Scheflan

The breaking strength of sized and unsized yarn. Edward Wood. *Cotton* (Atlanta) **104**, 45(Jan., 1940).—It has been found that 15% increased wt. in the warp yarn should give about 23% to 25% increased breaking strength. Properly cooked size mix in the size box will produce fairly consistent results. In some instances a decrease in twist will increase the breaking strength of the warp yarns in the cloth. If the yarn is spun with a little less twist than that giving the best skein breaks, when this twisting action takes place in the cloth the increase in the effective twist will bring each thread to its max. strength in the cloth where the ultimate test is anyway. W. H. Boynton

The microstructure of wool. II. Relationships between the curliness of Merino wool and refractive index. Kametaro Ohara. *Melliand-Textilber.* **20**, 326–8(1939); cf. *C. A.* **32**, 5633⁷.—Merino wool used in previous expts. was extd. with petroleum ether and dried and the Becke method used to det. the n_D^{23} of fibers embedded for various periods in mixts. of α-bromonaphthalene and oil of cloves. Tabulated data show (1) that after 2 days the outer side of the curly segments of the fibers had a lower n_D^{23} than the inner side and (2) that, as the period of contact with the embedding agent was increased, n_D^{23} for both outer and inner sides increased at different rates and approached the same upper limiting value after 6 and 20 days for inner and outer sides, resp. This suggests that the micellar structure of the outer side of the curly segments is less dense and requires longer for complete imbibition with the embedding medium. Perhaps the previously observed greater affinity for dyes of the outer side of the curly segments is due to the fact that the more open micellar structure is more favorable to fixation of larger dye particles. **III. Analysis of the swelling of curly wool.** *Ibid.* **21**, 1–3 (1940).—When curly wool fibers were mounted on microscope slides and treated either (1) with strong mineral acids (e. g., 62% H_2SO_4) or (2) at 75° with satd. aq. solns. of salts, e. g., $Ca(CNS)_2$, NaI, $Ba(ClO_3)_2$ or (3) with strong concd. org. acids, e. g., 80% AcOH, 85% HCO_2H, but not with weak concd. org. acids, e. g., 90% satd. citric acid or (4) with alc. NaOH, the swelling started at the outer side of the curve of the fiber and progressed continually across the fiber until the whole fiber was uniformly swollen. Fibrillar structure became clearly visible during the swelling process. The swollen parts appeared darker under crossed nicols. Swelling in aq. NaOH began both from the outer and inner sides of the curved fiber segments. J. W. Perry

The influence of moisture on the strength of cotton fabrics. M. V. Sadov. *Legkaya Prom.* **16**, No. 5, 84–8 (1937); *Chem. Zentr.* **1938, I**, 4398.—As a result of the change in its properties under the influence of atm. moisture, a yarn shows greater strength sometime after removal from the spinning machine (30 min.) than immediately thereafter. A rational schedule of operations is described for the collecting of the cops and testing of the yarn to det. such properties as tensile strength, fineness no. and extensibility. The procedure described should shorten to a min. the time (4–5 hrs.) between the first and last tests made on yarn of the same type and fineness and in this way eliminate differences in the measurements due to the effects of atm. moisture. M. G. Moore

Electrostatic charges on staple rayon when working in connection with spinning. R. Stoll. *Melliand-Textilber.* **21**, 3–6(1940).—Analysis of data on the intensity, in v., of electrostatic charge on staple rayon during spinning shows that the important factors are (1) the character of the rayon fiber, its moisture content and type of surface coating, if any, and (2) the intensity of the rubbing action as detd. by the coeff. of friction of the fiber surfaces, the area of rubbing, pressure on the rubbing surfaces and the speed of their relative displacement. Avoidance of card-

ing and spinning difficulties due to electrostatic charge is discussed. J. W. Perry

The German rayon and staple fibers in photomicrographs. B. Hauptmann. *Kunstseide u. Zellwolle* 22, 51-2(1940); cf. *C. A.* 34, 1181⁶.—Photomicrographs of 4 com. Cu rayon fibers are reproduced. M. P.

Funori: a new sizing agent for rayon. S. H. Kotak. *Indian Textile J.* 50, 119(1940).—Funori is a kind of seaweed growing in Japan and in Korea. It is dark pink in color and so must be bleached for use with textiles. $NaHSO_3$ is used and the bleached funori is then spread on a long wooden plank and sprinkled with hot water. It sticks together and is shipped in sheet form. Its compn. is: water 12.3, alginic acid 61.0, cellulose 26.0 and ash 0.7%. Advantages claimed for funori are: (1) increased elongation, pliability and strength of the sized rayon warp, (2) its neutral reaction rendering the addn. of alk. substances unnecessary, (3) no necessity for a desizing agent, (4) funori is not brittle in dry form, (5) the soln. does not putrefy even if stocked for several days and (6) the binding power of funori is less than that of starch but the viscosity is higher and less is needed, and (7) its emulsifying properties are good. W. H. Boynton

New advances in chemistry and processes for bleaching linen. R. Kuchinka. *Melliand-Textilber.* 20, 643-4, 706-9, 759-61, 804-6(1939).—Modern ideas as to the chemistry of the components of unbleached linen fibers are reviewed at length. Removal of undesirable lignin, pectin, protein, wax and fat and colored components with min. damage to the cellulose (I) can be accomplished only by careful process control. For this reason it is necessary to use dil. alk. solns. for bucking, to control the pH of the hypochlorite bleach so as to avoid a pH of 6-8 and extremes of high or low pH and to avoid the presence in H_2O_2 bleaches of catalysts, e. g., metals such as Fe, which catalyze conversion of the ions, O_2H^- or O_2^{--}, which bleach with min. damage to I, into atomic O having a strong degrading action on I. J. W. Perry

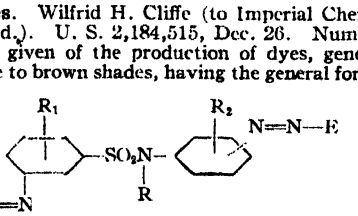
A method of bleaching semilinen fabrics. N. K. Semenov. *L'no-Pen'ko-Dzhutovaya Prom.* 8, No. 5, 46 (1938); *Chem. Zentr.* 1938, II, 3483.—Semilinen fabrics are woven from cotton yarn and linen yarn which has previously been semibleached by boiling twice and bleaching with Cl. In this process the linen yarn loses 18–20% of its strength. By the addn. of emulsifiers (kerosene and soap) during the boiling, boiling only once and bleaching are sufficient. The bleaching action is as effective, the strength of the yarn is increased, and the cost reduced. M. G. Moore

Modern mercerizing. I. Lewis Thompson. *Textile Recorder* 57, 33-5(Jan., 1940).—The year 1940 marks the 50th anniversary of the discovery of mercerizing cotton under tension for the production of luster. John Mercer patented a method of swelling cellulose by solns. of NaOH at room temps. and lower temps., also of producing the effect by means of certain concns. of H_2SO_4 at room temp. and concd. solns. of $ZnCl_2$ at a moderately high temp. The discovery of the conditions under which a high degree of luster can be obtained in the mercerizing process was made by Horace Lowe. **II.** *Ibid.* 31-3(Feb., 1940).—Long staple cottons give good results in mercerizing. The hairs in the yarn should be as parallel as possible and the NaOH must penetrate the fibers evenly and rapidly; both properties require a soft spun yarn. The temp. of the mercerizing liquor should not exceed 18°. Most modern mercerizing processes allow the material to shrink in the alkali, in order to assist thorough penetration, and then apply the tension later, immediately before or during the removal of the alkali. Max. luster and max. affinity for dyestuffs are not obtainable simultaneously. W. H. Boynton

Characteristics of textile casein. E. Pijanowski. *Poradnik Mleczarski i Fajczarski*, No. 23, pp. 19-22 (1938)(in Polish with English summary); *Dairy Sci. Abstracts* 1, No. 1, 24.—The general uses and properties of casein are given and a method for the prepn. of textile casein is outlined. Two samples of Italian manuf., 2 made by the Dutch method, 2 made locally and 1 sample of casein pptd. with lactic acid were fully analyzed chemically and physically and on this basis a standard is suggested for the compn. of textile casein. The Dutch method of manuf. dispenses with filters and is economical. C. L. B.

Deposition of artificial resins in textiles. Fritz Ohl. *Kunstseide u. Zellwolle* 22, 32-4(1940).—Cellulose fibers were impregnated with a soln. of 100 g. urea, 50 g. phthalic acid and 110 cc. H_2O, dissolved hot, and cooled; then 250 cc. of CH_2O soln. and some sucrose were added to prevent premature sepn. of resin with the subsequent pressure treatment. This resulted only in surface coating of the fibers, which was not very effective. Deposition of resin throughout the fiber was obtained by impregnating first with the urea-phthalic acid soln. and then adding the CH_2O during the pressure treatment. This treatment makes the fibers water- and wrinkle-proof and "animalizes" them with regard to their dyeing properties. Mark Plunguian

Damage done by alkalies. T. F. Heyes. *Textile Recorder* 57, 30–31, 33(Jan., 1940).—Faults often occurring in textiles, particularly in the case of wool and mixts. contg. wool, which are ascribable to the use of alkalies. W. H. Boynton



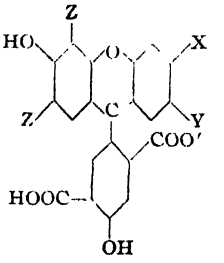
Application of light-weight and ultra-light-weight alloys in the textile industry. Albert Nau-Touron. *Bull. soc. ind. Rouen* 67, 61-76(1939).—A discussion. C. R. P.

Removing forty-one kinds of stains. Joseph F. Krawiec and Pauline B. Mack. *Laundryman* 6, No. 1, 5–7, 18–19; No. 2, 7-8, 18(1940).—Sp. instructions are given for removing 26 medicinal and 15 miscellaneous stains commonly met with in institutional laundering. In general the use of boiling soap baths and the repetition of multiple suds treatments is recommended as being less harmful to the fabric than increasing the amt. of bleaching agent. Many stains require special treatment. C. R. P.

Utilization of seed of *Plantago psyllium* [for dye printing] (Bottini) **27**. Ethers and ether-esters of lac and their polymerization [impregnating and coating agents for textiles] (Gidvani) **26**. Treatment of S dye waste for activated sludge process (Porges, Miles) **14**. Synthesis of analogs of Fast Black Base LB (Bogoslovskiĭ, Tsil'man) **10**. Naphthoylenediethoxybenzimidazole and structure of Indanthrene Red-Brown 5 RF. (Grachev) **10**. Condensation products of *m*-dialkylaminobenzaldehyde with compds. contg. reactive methylene groups [dyes] (Cocker, Turner) **10**. Elec. indicator and control app. for impurities in tank liquors of dye works (U. S. pat. 2,183,584) **1**. Softening agents for textile fabrics (U. S. pat. 2,183,721) **23**.

Monoazo dyes. Richard Fleischhauer (to General Aniline Works). U. S. 2,183,489, Dec. 12. From components such as 2-aminobenzenesulfonic acid and 5-acetylamino-2-naphthol-8-sulfonic acid, dyes are produced of the general formula 1-(HO_3S-aryl-N:N)-2-HO-5-acylamino-8-$HO_3SC_{10}H_4$, where aryl means a radical of the benzene series, the —SO_3H group being attached thereto in ortho position to the azo group and no halogen atom standing in the other ortho position to the azo group, which dyes dye wool and silk clear orange shades of good fastness to light.

Disazo dyes. Wilfrid H. Cliffe (to Imperial Chemical Industries Ltd.). U. S. 2,184,515, Dec. 26. Numerous examples are given of the production of dyes, generally dyeing orange to brown shades, having the general formula



in which the group —N=N—E is in one of the positions meta and para to —NR—; R is one of a group consisting of alkyl having 1–4 carbons and aralkyl; R_1 and R_2 are

from the group consisting of H, alkyl, alkoxy and halogen; and E is the residue after coupling in basic medium of an azo dye coupling component of a group consisting of naphtholsulfonic acids, aminonaphtholsulfonic acids, alkylaminonaphtholsulfonic acids, hydroxyalkylaminonaphtholsulfonic acids, aralkylaminonaphtholsulfonic acids, acylaminonaphtholsulfonic acids, arylpyrazolonesulfonic acids and *N*-substituted amino derivs. of naphtholsulfonic acids, the *N*-substituted amino group being —NHC_6H_3XY, where X is not more than two members of the group consisting of H and methyl, and Y is one of a group consisting of H, Cl and sulfonic acid.

Copper compounds of primary resorcinol trisazo dyes. Fritz Dobler and Hans Buess (to J. R. Geigy A.-G.). U. S. 2,183,673, Dec. 19. A process for the production of Cu compds. of primary resorcinol trisazo dyes involves treating a water-sol. Cu salt with a trisazo dye of the general formula, 1,3-$(HO)_2C_6H(N:NR_1)(N:NR_2)(N:NR_3)$, where R_1 means the radical of the first coupled diazo compd. made from a negatively substituted *o*-aminophenol, R_2 means the radical of the secondly coupled diazo compd. made from any desired aromatic amine and R_3 means the radical of the finally coupled diazo compd. made from an aminodiphenylaminesulfonic acid, the trisazo dye being made in this order of coupling in alk. soln. The resulting Cu compds. give clear brown dyeings on silk and *leather*.

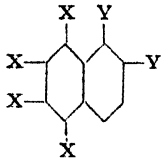
Chromable dyes of the triarylmethane series. Wilhelm Eckert and Karl Schilling (to General Aniline Works). U. S. 2,183,237, Dec. 12. Several examples are given of the production of dyes, dyeing wool orange-yellow to red tints, made darker and faster by after-chroming, having the general formula

where X represents an ethyl-substituted amino group, Y H or methyl, Z H or Br. Cf. *C. A.* **34**, 1191[7].

Dyes of the naphthalene series. Rudolf Robl (to General Aniline Works). U. S. 2,183,870, Dec. 19. Dyes suitable for dyeing acetate rayon greenish blue shades are produced by causing a naphthazarin intermediate product in the presence of a reducing agent such as Na hyposulfite to react with a *p*-aminophenol benzyl ether and oxidizing the leuco compd. thus formed. U. S. 2,183,871 relates to dyes for cellulose esters and ethers prepd. by condensation of a naphthazarin intermediate product with an alkylamine, aralkylamine or cycloalkylamine in the presence of a reducing agent and oxidizing the leuco compds. formed.

Vat dyes of the anthraquinone series. Otto Schlichting and Karl Koeberle (to General Aniline Works). U. S. 2,183,873, Dec. 19. By various reactions, vat dyes are obtained which dye fibers such as cotton generally yellow to brown shades and which have the general formula $A(NHCORCH_2N(X)Y)_n$, where A stands for a radical of the anthraquinone series, R for a benzene radical, X for H or alkyl, Y for H or an amino, alkyl, aralkyl, cycloalkyl, aryl or heterocyclic radical and *n* for an integer less than 3. Numerous examples are given.

Reduction products of *Bz*-2,*Bz*-2′-dihydroxydibenzanthrone (dyes and intermediates). Otto Stallmann (to E. I. du Pont de Nemours & Co.). U. S. 2,183,625, Dec. 19. Various examples with details are given, among which is the production of a stable reduction product of *Bz*-2,*Bz*-2′-dihydroxydibenzanthrone in the free hydroxy form which on isolation is a brownish black cryst. solid stable to air oxidation under ordinary atm. conditions, which dyes cotton from a blue alk. hyposulfite vat in olive shades; the compd. is sol. in concd. H_2SO_4 with a blue color from which it may be pptd. without decompn.; it is obtainable by heating an alk. hyposulfite vat of *Bz*-2,*Bz*-2′-dihydroxydibenzanthrone, the alky. of which has been reduced to a pH value of from 9 to 12 at from 60–90° until the mono alkali metal salt has been completely pptd., filtering off the alkali metal salt and heating the same with acids at a temp. of about 60°. The products may be brominated if desired and the brominated products may be used in prepg. compds. for *coloring oils, gasoline*, etc., generally giving olive shades. Cf. *C. A.* **33**, 4053[8]. U. S. 2,183,626 gives numerous examples involving treating leuco dibenzanthrones or their stable reduction derivs. with an alkylene oxide such as ethylene oxide at temps. of about 100–190° for the production of hydroxyalkyl leuco ethers which are generally of red color, relatively insol. in water but highly sol. in org. solvents such as benzene and which may be further esterified with inorg acids to form water-sol. esters. U. S. 2,183,627 relates to prepg. alkylol and cycloalkylol ethers of *Bz*-2,*Bz*-2′-dihydroxydibenzanthrone by heating *Bz*-2,*Bz*-2′-dihydroxydibenzanthrone with an α,β-alkylene oxide until one alkylol group has been introduced into the mol., further treating the monoalkylol ether of the *Bz*-2,*Bz*-2′-dihydroxydibenzanthrone with an alkylating agent substantially completely to etherify the remaining *Bz*-2′ hydroxy group and sulfonating the free OH group of the alkyol ether radical by subjecting the resulting compd. to the action of a sulfonating agent of the class consisting of concd. H_2SO_4, SO_3 and SO_3-liberating agents, at temps. below 100°. *Bz*-2,*Bz*-2′-Dihydroxyisodibenzanthrone may also be used as initial material, and products are obtained which dye fast green or blue shades. Various examples with details are given. U. S. 2,183,628 relates to prepg. long-chain aliphatic acid leuco esters of dibenzanthrone compds., such as the dilaurate of *Bz*-2,*Bz*-2′-dimethoxydibenzanthrone, by treating a leuco dibenzanthrone compd. or stable reduction deriv. with an aliphatic acid chloride or anhydride. Products are obtained suitable for coloring oils, etc., and numerous examples with details are given.



Mordant. Harold E. Bode (to Corn Products Refining Co.). U. S. 2,183,390, Dec. 12. See Can. 383,688 (*C. A.* **33**, 9008[4]).

Dyeing materials such as acetate rayon containing polyvinylchloroacetate. Paul Schlack (to I. G. Farbenind. A.-G.). U. S. 2,183,754, Dec. 19. In dyeing a fibrous textile material contg. nonbasic radicals capable of being converted into basic condition or contg. basic radicals capable of being converted into more strongly basic condition, by treatment with a medium contg. a dye having an acid group, there is added to such medium a substance, such as ethylenethiourea, which will produce such a conversion of such radicals in the textile material. Numerous examples are given.

Dyeing cellulose derivatives such as cellulose acetate. James G. McNally and Joseph B. Dickey (to Eastman Kodak Co.). U. S. 2,183,997, Dec. 19. Dyeing, generally yellow shades, is effected by use of nuclear nonsulfonated aryl azo derivs. of a 1,3-cyclohexanedione having an alkyl group in its 5-position. U. S. 2,183,998 relates to azo dye compds. suitable for like use and contg. an aryl nucleus of the benzene or naphthalene series the aryl nucleus of which carries a phosphoric acid ester group or a thiophosphoric acid ester group attached to an aliphatic radical contg. at least 2 C atoms which is joined to the aryl nucleus through an O atom which is a nuclear substituent of the aryl nucleus. Numerous examples are given. U. S. 2,183,999 relates to azo dyes suitable for like use which have the general formula R—N=N—R′ in which R represents the residue of a nucleus of the benzene series or benzothiazole series and R′ represents the residue of a 1-amino-5-hydroxynaphthalene or a 1-amino-5-alkoxynaphthalene nucleus in which the component from which R is derived contains a tetrahydrofuryl group attached to the N atom of the amino group in the

1-position through the C atom in the 2-position by a said. straight chain hydrocarbon radical.

Dyeing furs such as white rabbit fur. Mordecai Mendoza and Geo. S. J. White (to Imperial Chemical Industries Ltd.). U. S. 2,183,752, Dec. 19. A process of dyeing fur comprises pretreating the fur by the chrome-tannage process, giving the fur a pH between 6 and 7, immersing the pretreated fur in an approx. neutral soln. of a dye heated to about 40–90°, the dyes being made by coupling diazotized 4,6-dinitro-2-aminophenol and a coupling component represented by the formula

in which one X is hydroxy and the other X's are H and one Y is H and the other Y is amino, NH-alkyl, NH-aryl, NH-hydroxyalkyl, dialkylamino or NH-acyl; and continuing the immersion with periodic addns. of small amts. of org. acids until the dyeing of the fur is completed.

Color printing compositions for use on vegetable and animal fibers. Charles Graenacher and Max Matter (to Soc. pour l'ind. chim. à Bâle). U. S. 2,184,495, Dec. 26. Printing compns. are used contg. a dye such as Helindon Violet BB, which is fixed in insol. form on the fiber, a thickening agent such as "potash thickening" and ethylthioglycolic acid amide or other acid amide of the general formula $R_1SR_2CONR_3R_4$, where R_1 stands for a lower alkyl, hydroxyalkyl or alkoxyalkyl radical, R_2 stands for methylene, and R_3 and R_4 stand for H or an alkyl radical, which serves as an assistant.

Fixing coloring agents on cellulose derivatives such as cellulose acetate. Albert Mellor and Wm. Pool (to Celanese Corp. of America). U. S. 2,184,559, Dec. 26. App. is described, and a process of fixing org. coloring matter such as a direct dye on materials such as fabrics of cellulose acetate by subjecting the material, carrying the coloring matter, to the action of the satd. vapor of an org. liquid such as dichloroethylene which is chemically inert to the coloring matter.

Polyhydroxyfuchsone derivatives etherified with aliphatic groups. Zoltan Foldi (to Chinoin Gyógyszer és Vegyészeti Termékek Gyára R. T. (Kereszty és Wolf). U. S. 2,184,491, Dec. 26. *Dyeing, therapeutic* or *bactericidal compds.* are produced by a process which comprises oxidizing leuco triphenylmethane derivs. the benzene rings of which are substituted by substituents from the group consisting of H, alkyl, hydroxy, alkoxy, carboxy, sulfo, halogen and nitro; the total number of hydroxy and alkoxy substituents being at least 4 but not more than 6, while the no. of alkoxy substituents present is at least 1 and the number of hydroxy substituents present is also at least 1, one of the hydroxy substituents being in para position to the methane C atom; the hydroxy and alkoxy groups being distributed among the benzene rings in such manner that no benzene ring contains more than 2 members of the class consisting of these groups; 2 members of the group consisting of hydroxy and alkoxy being in mutual ortho position on one benzene ring. Details are given of the production of compds. such as: 3,3'-dimethoxy-4'-hydroxyfuchsone, m. about 186° and forming a cryst. hydrochloride; *m*-dimethoxy-*p*-dihydroxyfuchsone, decompg. about 248° and forming a hydrochloride decompg. about 203°; *m*-nitro-*m*-dimethoxy-*p*-hydroxyfuchsone, forming a hydrochloride decompg. about 152°; *m*-nitro-*m*-dimethoxy-*p*-dihydroxyfuchsone hydrochloride, decompg. about 192°; the corresponding free fuchsone, m. (decompn.) about 179°; *o*-diisopropyl-*m*-dimethyl-*m*-methoxy-*p*-dihydroxyfuchsone, m. about 230° and forming a hydrochloride in cryst. needles of metallic luster; *m*-methoxy-*p*-dihydroxyfuchsone, m. about 275° and forming a hydrochloride m. about 206°; *o*-dimethoxy-*p*-dihydroxyfuchsone hydrochloride, not m. up to 280°; *m*-amino-*m*-dimethoxy-*p*-dihydroxyfuchsone; *m*-amino-*m*-dimethoxy-*p*-hydroxyfuchsone; the Ca salt of *m*-methoxy-*p*-dihydroxyfuchsonesulfonic acid; and *m*-dimethoxy-*p*-dihydroxyfuchsone-*m*-carboxylic acid. Cf. *C. A.* **33**, 6346[1].

Apparatus for bleaching bast fibers with chlorine. Philipp Siedler, Erich Kayser, Helmuth Korte and Wilhelm Waibel (to I. G. Farbenind. A.-G.). U. S. 2,184,477, Dec. 26. An app. for chlorinating and bleaching bast fibers, for instance linen, hemp or the like by satd. or supersatd. Cl water comprises a bleaching vessel which is provided with devices for placing the material to be treated on cross wound bobbins, a device for producing the Cl water, a system of tubes and a pump to provide a continuous circulation of the Cl water through the bleaching vessel and the device for producing the Cl water and means for adjusting and maintaining the concn. desired of the Cl water. Cf. *C. A.* **33**, 4799[1].

Textile products. Joseph F. X. Harold. U. S. 2,184,041, Dec. 19. A vegetable textile material in natural form such as cotton is treated, as by nitration, to render it sol. without destroying its form, and is used together with one or more relatively insol. materials such as unnitrated cotton from which the solubilized material may be subsequently removed by use of a selective solvent.

Oil for treating textile materials. Walter Garner. U. S. 2,184,040, Dec. 19. A nonstaining oil not darker than a medium color is prepd. by incorporating in a textile oil, such as arachis oil, contg. unsatd. substances about 0.1–0.25% of solid S and heating the mixt. at the lowest temp. which will render the oil nonstaining (suitably about 180–200°).

Cleaning wool. Franklin H. Mackenzie (to American Chemical Paint Co.). U. S. 2,183,142, Dec. 12. See Brit. 495,193 (*C. A.* **33**, 2736[3]).

Treating wool-scouring and other liquors coataining grease and soaps. Gwynfred Jones and J. W. McGregor and Sons Ltd. Brit 508,371, June 29, 1939. The oxide or hydroxide, or normal or basic salt, of a metal, e. g., Ca, capable of forming (*a*) insol. soaps, (*b*) an insol. hydroxide of the metal or an insol. normal or basic salt by combination with a polybasic acid, and (*c*) a sol. acid salt by combination with the polybasic acid, is added to the effluent, which is then subjected to the action of the acid or its anhydride, which may be in gaseous form, e. g., CO_2 or a gas contg. CO_2, under suitable conditions and in sufficient amt. to form sol. acid salts with the alk. carbonates in the scouring effluent and also to form the sol. acid salt of the aforesaid metal, which salt reacts with the soaps and grease to cause a pptn. thereof, the ppt. being then removed. The sol. acid salt (*c*) may be added directly to the liquors instead of being formed therein. The pptn. may be made more complete by the addn., preferably after the acid or gas treatment, of $Al_2(SO_4)_3$, $CaCl_2$, $CaSO_4$, $MgCl_2$, $MgSO_4$, $FeSO_4$, etc., which either form insol. soaps themselves or cause them to be formed by reaction with other compds. added to or already present in the liquor. An absorbent or coagulant such as Californian bentonite may be added, preferably after the acid or gas treatment. The crude grease may be extd. from the ppt. (without previous drying) by a solvent that forms an azeotropic min.-boiling mixt. with H_2O, e. g., C_6H_6, toluene or an appropriate aliphatic alc. or a mixt. of these. The crude grease may be purified by extn. with a mixt. of Me_2CO and AcOEt or AcOMe, which leaves undissolved a residue of impure metallic soaps.

Combination yarn. Fred C. Werber. U. S. 2,183,703, Dec. 19. A method of making a combination yarn consists in helically assembling a covering yarn which has been colored with a permanent dye with a core yarn, the latter being an undyed hard-twisted crepe yarn and having a size, the twist of the covering yarn being lower than the twist of the core yarn, the turns of the covering yarn being spaced from each other, and then desizing the core yarn so as to diminish the length thereof and to bring the turns of the covering yarn close to each other

so that the turns substantially cover the core yarn, the coloring of the covering yarn being substantially unaffected by the desizing step.

Production of packages of yarns or similar textile materials. Henry Dreyfus. Brit. 508,700, July 5, 1939. The necessity for unwinding and rewinding packages of yarns, etc., having a basis of cellulose acetate or other org. deriv. of cellulose, during treatment thereof is avoided by coating the barrels of the bobbins on which the packages are to be wound with a solid substance that is sol. or readily dispersible in H_2O and can therefore be readily removed subsequently without affecting the material wound thereon. A H_2O-sol. carbohydrate, e. g., glucose, dextrin, cane sugar, or a carbohydrate deriv. sol. or dispersible in aq. media as a result of degradation or of the presence of a hydrophile group in a substituent radical, e. g., hydroxyalkyl ethers of cellulose produced as in Brit. 166,767 (*C. A.* **16**, 830) and 277,721 (*C. A.* **22**, 2663) and carboxyalkyl ethers of cellulose produced as in Brit. 343,521 (*C. A.* **25**, 5557), cellulose esters produced as in Brit. 344,775 (*C. A.* **26**, 318), H_2O-sol. synthetic resins such as polymerized acrylic acid or partially sapond. polyvinyl ester resins, or proteins sol. or dispersible in aq. media may be used for the coating.

Rayon thread. Charles A. Huttinger (to Acme Rayon Corp.). U. S. 2,184,144, Dec. 19. Various operative and structural details are described, of an app. for imparting uniform properties to the thread during stretching consisting of a support, a pair of spaced idlers mounted on the support for cooperative action and whose axes are nonparallel, one of the idlers having a smooth thread-engaging surface, and a paddle-wheel secured to the idler and having blades extended outwardly beyond the thread-engaging surface, the other idler being formed with a thread-engaging groove.

Sizing textile materials such as viscose rayon. Herbert Rein (to I. G. Farbenind. A.-G.). U. S. 2,183,226, Dec. 12. A process is employed which involves impregnating textile materials with an aq. soln. of a water-insol. resin contg. carboxylic acid groups made sol. in water by treatment with an excess of a concd. soln. of urea, thiourea or methylurea, the ratio of the resin by wt. to the concd. soln. by vol. being about 1:about 6 to 12 and the ratio by wt. of the resin to the urea in the concd. soln. being about 1:about $1/2$ to 2

Treating cotton yarn to give it luster. Wm. H. Furness (to American Rayon Co.). U. S. 2,183,477, Dec. 12. A process for treating cotton yarn involves subjecting it to a NaOH soln. of approx. mercerizing strength and subsequently, while still contg. the combined NaOH, to a soln. consisting essentially of 2 portions, one a soln. of Cu sulfate-ammonia and NaOH and the other tetrammonium Cu sulfate, and allowing the yarn to remain in the soln. just long enough to remove NaOH from the fuzz and thereby bring about the soln. of the fuzz, the soln of Cu sulfate-ammonia and NaOH comprising about 50–70% of the soln. and having a mol. ratio of one mol. of $CuSO_4$ to 2 mols. of NaOH and having sufficient NH_3 to have stability in the range of working temp. Cf. *C. A.* **33**, 2737[2].

Ornamenting textile materials. Fridolin Hefti (to Akt.-Ges. Cilander). U. S. 2,184,593, Dec. 26. Loose ornamenting material such as a powd. or flaked metal or pigment is applied to a face of a web of textile material in a substantially continuous layer, the textile material is printed with an adhesive on the back face in conformity with a pattern to be produced by deposits of the added material on the front face of the web, and the textile material is then immediately wound in a tight coil so as to transfer part of the deposited material to its back face, and the adhesive is dried to fix permanently the ornamenting material in position on both faces of the textile material, and surplus ornamenting material is mechanically removed where it has not adhered. App. is described.

Lightweight, air-transmissive fabrics for garments. Emil Knup and Franz Naef (to Textilwerk Horn A.-G.). U. S. 2,184,600, Dec. 26. A method of producing lightweight, air-transmissive, waterproof fabric for garments having high resistivity to impairment of its waterproof property from the effects of washing, involves impregnating a textile fabric having small pores substantially of the size of the pores of a fabric of the type 70/70, 40/40 with liquid paraffin in a quantity insufficient, when dry, to close the pores of the fabric, drying the paraffin to solid state, then impregnating the fabric with from about 10 to 20 g. per sq. m. of vinyl acetate artificial resin, then impregnating the fabric with paraffin in liquid state, and then calendering the fabric at a temp. of about 25°, at which temp. the paraffin and resin jointly will not become viscous so as to prevent spreading of the impregnants and closing the pores of the fabric from the effect of calendering.

Porous elastic fabrics. Fernand F. Schwartz (to American Ecla Corp.). U. S. 2,184,158, Dec. 19. A process for the manuf. of a porous elastic fabric comprises applying by spraying to the projecting portions of an extensible fabric a series of coatings of latex in the form of a spray the droplets whereof having a diam. of 0.1 to 0.3 mm. and a rate of coagulation between $1/2$ and 1 sec. the spraying means being situated between 30 and 40 cms. from the surface of the fabric and the latex being forced under an air pressure of 2 to 3 atm., and coagulating and drying the coatings before applying the succeeding coating. Cf. *C. A.* **34**, 895[2].

Fabrics impermeable to warfare chemicals. G. van der Veen, G. Beins and H. J. Smidt. Dutch 47,200, Nov. 15, 1939. Cotton fabric is coated on one side with latex and vulcanized. The material is then impregnated from the other side with a 35% aq. soln. of gum arabic to which 10% glycerol is added. Excess soln. is removed, the material slightly dried over a warm roll, the treated side covered with pulverized wood and coated over with latex. This is vulcanized or treated with alc. shellac. The material resists mustard gas. Several other combinations for the same general purpose are discussed.

Sulfonated product for use as a textile- and leather-processing assistant. Albert F. Bowles and Saul Kaplan (to Richards Chemical Works, Inc.). U. S. 2,183,929, Dec. 19. Use is made of a neutralized sulfonated product of the material obtained by condensing an amino compd. such as urea or NH_3 with a condensation product derived from malonic acid and oleic aldehyde or other aldehyde contg. 2–18 C atoms per mol. Cf. *C. A.* **34**, 2102[9].

Mothproofing wool, felt, furs, feathers, etc. Wilfrid Lowe. U. S. 2,184,147, Dec. 19. Protection from moth larvae is effected by immersing materials in a warm aq. soln. of Cr fluoride of about 0.8% strength, followed by hydro-extn., as by squeezing, and air drying at a temp. of about 65° or higher.

Waterproof apparel. Annelies Othmer and Karl Flaig. Brit. 508,423, June 30, 1939. The apparel is made of natural or synthetic rubber, films of artificial rubber-like substances, textile material coated on 1 side with such a film or acryl, vinyl or butyl resins producing latex-like emulsions, or a double layer of textile material in between which is provided a film of this kind, textile material rendered H_2O-proof or H_2O-repellent by impregnation, e. g., with Al oxides, salts or soaps, if desired in the presence of paraffin, etc., or American cloth. The film may be sprinkled with powder, e. g., talcum, to decrease its adhesivity, before impregnation. The apparel may be made of rayon in the form of continuous or staple fibers treated with a crease-resisting agent, e. g., a CH_2O or urea synthetic resin.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

The paint and varnish industry. Robert J. Moore. *Am. Paint J.* **24**, 18–20, 22, 64–7, 69, 71(Feb. 12, 1940). W. H. Boynton

Emulsified bituminous paints. A. S. Korzhuev and V. V. Gridchina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 259–61 (1939).—A discussion of the methods of prepn. and phys. properties of bituminous paints based on the literature and some exptl. evidence. Chas. Blanc 2

Formation and deterioration of paint films—changes in films of methyl esters of several unsaturated fat acids under exposure to ultraviolet light. J. L. Overholt and A. C. Elm. *Ind. Eng. Chem.* **32**, 378–83(1940).—Films of the Me esters of oleic, linoleic, linolenic and eleostearic acids were exposed to ultraviolet light in a const.-temp. room at 65% relative humidity and 25°. At intervals samples of the exposed esters were analyzed for change in wt., degree and type of unsatn., degree and type of oxidation, ultimate analysis, mol. wt., viscosity, d. and *n*. Changes in the above properties during the 1st 1000 hrs. are shown by a series of graphs. The esters gain wt. during the 1st stages of exposure proportional to their unsatn. and later lose wt. owing to decompn. The I addn. values give indications of a 3-stage drying process: an induction stage, a stage of rapid decrease in unsatn. which corresponds to the max. in peroxide content and a less definite stage with uncertain results. The highest peroxide concn. present at any time even in Me linoleate is equiv. to only a fraction, of one double linkage. OH reaches its max. after the peroxides have started to decompose. Mol. wts. measured in C_6H_6 and *tert*-BuOH show that the eleostearate passes through a max. shortly before its max. peroxide concn. is observed. There is little change in mol. wts. of the others although viscosity increases to 100 times the original value. H. M. Stark 3 4 5

Silver (aluminum paint) in the South. S. H. Coleman. *Southern Power and Ind.* **58**, No. 2, 40–5(1940).—Aluminum paint has the advantage of reducing the effect of light on the vehicle, reducing moisture penetration, high resistance to corrosion and high reflectivity for light and radiant heat. The characteristics of varnish and lacquer vehicles are briefly reviewed. Details of mixing and applying are given. R. W. Ryan 6

Adhesion of paint films to plaster. H. M. Llewellyn and H. J. Eldredge. *Oil Colour Trades J.* **97**, 294, 296 (1940).—A discussion of blistering, peeling and flaking, which affect decorations on plastered surfaces, and of means of preventing their occurrence. Conclusions are: (1) a linseed oil primer applied to Keene's cement following the trowel is capable of giving satisfactory adhesion, but higher values are obtained if the priming is deferred, (2) the residual adhesion is greater for a Keene's cement primed wet than when primed dry, (3) it is essential with anhyd. plasters that any primer applied after the trowel should not contain too much oil, (4) it seems that the chief justification for applying a coat of primer at an early stage is that such a coat retards the evapn. of water from the plaster surface and (5) it is important to avoid any possibility of sealing in moisture permanently. Investigation of cases involving defective paint work on Keene's cement often showed that the further coats of oil paint had been applied too soon after the priming coat. W. H. Boynton 7

An apparatus for the accelerated evaluation of heat-resisting paints. G. W. Ashman and S. Werthan. *Paint Ind. Mag.* **55**, 47–9(1940).—The app. consists of an electrically heated cylindrical unit that is operated outdoors, replaceable test sections 3 in. in diam. by 32 in. in length (7.6 cm. × 81.3 cm.) of sheet metal pipes that entirely cover the heater, and suitable racks for unheated outdoor exposure of the tests. The app. is mounted outdoors in an upright tilted position that affords an exposure of about 70° from the south. The paints to be tested are applied in bands on the replaceable test cylinders; several paints and a standard finish of known value may be painted on a single tube. W. H. Boynton 8

The Pallava paintings at Conjeevaram—an investigation into the methods. S. Paramasivan. *Proc. Indian Acad. Sci.* **10A**, 77–84(1939).—The painted stuccoes in the Kailasanatha and Vaikunthaperumal temples were done in a lime medium on a carrier of sandstone. The ground was a rough plaster of lime and sand, 1.5–4.1 mm. thick, over which was a 0.3-mm. lime wash and a 0.3-mm. lime-pigment layer contg. yellow ocher, red ocher, terre-verte, C and lime. The lime contained no gypsum and was evidently well purified and not hydraulic. Org. binder was found only in the black, where it was required to aid wetting of the pigment. Wm. E. Trout, Jr. 9

Paint baking with near infrared. H. J. Bennett and Howard Haynes. *Chem. & Met. Eng.* **47**, 106–8(1940).—Advantages of, and equipment for, drying lacquers and enamels by means of incandescent lamps are described. E. H.

Indirect-fired baked-enamel oven. Hugh R. Lamberth. *Gas* **16**, No. 2, 34–5(1940).—Enameled wall board is baked at 250°F. for the surface coat and at 300°F. for the final coat in a special oven insulated with 3-in. granulated rock wool. Combustion products do not reach the wall board directly but are mixed with furnace atm. and recirculated through the oven by means of a blower. A max. temp. difference of 5°F. is realized throughout the oven, and this oven is also applicable to other enameling processes at temps. up to 500°F. R. W. Ryan 10

Urea-formaldehyde film-forming compositions—enamel formulation, properties and durability. T. S. Hodgins, A. G. Hovey and P. J. Ryan. *Ind. Eng. Chem.* **32**, 334–45(1940).—Urea-resin coating solns., both by themselves and in combination with alkyd resins and plasticizers, are discussed as to reactivity, stability, solvent tolerances and durability on exterior exposure. Recommendations are made for baking schedules and pigmentation. A. F. Shepard 11

Luminescent pigments and paints—a bibliography. H. Courtney Bryson. *Oil Colour Trades J.* **97**, 245–7 (1940); cf. *C. A.* **34**, 2188⁹.—A list of 320 references. W. H. Boynton 12

New developments in the grinding of paint products. Richard L. Cawood. *Am. Paint J.* **24**, 55–8, 60, 62(Feb. 26, 1940).—The high-speed Cr-Mn ball mill saves time in grinding, saves floor space and provides highest economy in the use of power, labor, etc. Jacketed mills provide close temp. control. W. H. Boynton 13

Machines for grinding pigments in paint and lacquer industry. N. A. Kozulin. *Org. Chem. Ind.* (U. S. S. R.) **6**, 223–7(1939).—Various types of foreign grinding machines are described. Chas. Blanc 14

Vacuum filter for pigment colors. N. A. Kozulin, D. G. Khazin and V. M. Gokhberg. *Org. Chem. Ind.* (U. S. S. R.) **6**, 317–18(1939).—A stoneware conical vessel is fitted with a stirrer and porous porcelain tubes, through which the liquid and water are sucked during vacuum filtration and washing. Construction and operation details are given. Chas. Blanc 15

The properties of white pigments. Harley A. Nelson. *Am. Paint J.* **24**, 7–9, 24–6, 28(Feb. 19, 1940).—A discussion of the white opaque pigments and the low-*n* pigments. Optical properties and phys. and chem. characteristics are outlined, and the pigments are classed as (*A*) high-*n* group, which is subdivided into primary and composite pigments and (*B*) low-*n* pigments. W. H. Boynton 16

Production of lithopone. Ch. A. Sobolevskil. *Org. Chem. Ind.* (U. S. S. R.) **6**, 324(1939).—The quality of Soviet lithopone is criticized and possible improvements in the methods of production are suggested. C. Blanc 17

Preparation of ferriferous red ocher with lower oil capacity. V. E. Tartakovskaya and Yu. G. Khazina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 256(1939).—The cover- 18

ing and brushing properties of oil paints were considerably improved and the contents of oil reduced by the use of Fe ocher calcined at 800° for 30 min. The optimum results were obtained with an ore contg. Fe_2O_3 72.5, SiO_2 17.5, Al_2O_3 3.45, sol. salts 0.84 H_2O 0.5 and volatile matter 3.6%. Chas. Blanc

Some notes on zinc oxide in an alkyd vehicle. A. C. Eide and Harlan A. Depew. *Am. Paint J.* **24**, 49–54 (Feb. 26, 1940); cf. *C. A.* **33**, 4802[8].—ZnO is especially desirable when used with tinting pigments that are sensitive to light. The outstanding factor in the choice of a desirable ZnO is the absence of colloidal material, since the fine particles in ZnO cause very bad fading. A slight acicularity reduces the fading but too much holds back the initial gloss. Cofumed leaded ZnO and a blended high quality leaded ZnO weathered very well. Absence of colloidal fines in the ZnO produces the following advantages: (1) better maintenance of luster, (2) less chalking and fading and (3) a better luster on polishing. Also in *Paint Ind. Mag.* **55**, 85–6. W. H. Boynton

An ancient Egyptian marking ink. C. Ainsworth Mitchell. *Analyst* **65**, 100–1(1940).—Three small pieces of linen fabric were found in the rubble filling of the shaft of a tomb dating from the Second Dynasty at Saggara, near Cairo (the ancient capitol of Memphis). The dynasty ended in 2980 B.C. and the tomb is probably much earlier than this. The pigment dissolved with difficulty in hot HCl and gave the usual reactions for Fe. The markings were probably made with Fe oxide. The unintentional production of an Fe "mold" by laundries on modern linen suggests the way in which the Fe oxide may have been fixed. The markings behave like Fe oxide pigments under ultraviolet light and give a black "fluorescence."
W. T. H.

Synthetic resins for printing inks. H. C. Cheetham. *Am. Ink Maker* **18**, No. 2, 29, 31, 33(1940).—The wide variety of resins now available are considered with respect to the properties that they impart to inks. Particular attention is paid to the types of drying encountered (oxidation, gelation, penetration, evapn. and curing).
L. Wilson Greene

Developments in domestic oils. Louis J. Reizenstein. *Am. Paint J.* **24**, 56, 58, 60, 62–4(Mar. 4, 1940).—Examples are given of certain oil combinations for specific applications such as gloss finishes, flat finishes, furniture and household enamels, finishes for porous surfaces, interior varnish finishes, resins for use in place of varnishes, exterior finishes, paints for metal surfaces, etc. Imported oils are not needed since the advent of a no. of American synthetic resins which may be compounded to produce satisfactory results. Performance tests are briefly reviewed. W. H. Boynton

Chemical constitution of thickened linseed oil. A. Paleni. *Chimica e industria* (Italy) **22**, 5–7(1940).—The mol. refraction of linseed oil before and after thickening by boiling out of contact with air, as well as of the acids obtained by its sapon., is practically const. This indicates that the thickening is due not to polymerization, but rather to some other form of mol. assocn. which does not affect the glyceride constituents of the oil. The explanation may be based on the theory of colloids. Changes in the I no., etc., are not considered to be of sufficient importance to be used as a basis for upholding the theory of polymerization. A. W. Contieri

Use of castor oil in place of linseed oil in lacquer and paint industry. V. O. Solienko. *Org. Chem. Ind.* (U. S. S. R.) **6**, 310–13(1939).—The satisfactory results in the production of alkyd lacquers and paints at the Krasnopresnenskiĭ plant from oxidized castor oil are reviewed and further tech. improvements are suggested. C. Blanc

Tung-oil conservation. C. F. Pickett. *Official Digest Federation Paint & Varnish Production Clubs* No. **189**, 354–66(1939).—A discussion of possible methods of conserving tung oil by substitution of other oils such as oiticica or Cicoil, dehydrated castor oil and perilla. Some formulations are given to indicate the use of these oils to overcome deficiencies in viscosity, drying and water and chem. resistance due to omission of tung oil from formulations. H. M. Stark

Tall oil as a raw material in lacquer and paint industry. P. M. Romanova and A. K. Kotlyar. *Org. Chem. Ind.* (U. S. S. R.) **6**, 257–8(1939).—Excellent results are tentatively reported in the production of alkyd lacquers from tall oil and semidrying oils (cottonseed, sunflower and soybean oils). The lacquers and the resulting paints contg. ZnO and lampblack in their drying and weathering properties and in resistance to water and oil proved to be superior to the products obtained with linseed oil. The best results were obtained from the resin contg. tall oil 36.36, semidrying oil 11.23, phthalic anhydride 33.1 and glycerol 19.31%. Cf. Schlenkert, *C. A.* **32**, 8800[8].
Chas. Blanc

Petroleum naphthas and thinners. R. D. Armsbury. *Official Digest Federation Paint & Varnish Production Clubs* No. **189**, 366 71(1939).—A discussion of petroleum naphthas in the 3 classifications which are available for use in paints: (1) aliphatic (2) high aromatic and (3) synthetic. Tests for volatility and solvent power are reviewed. H. M. Stark

Ethers and ether-esters of lac and their polymerization. B. S. Gidvani. *London Shellac Research Bur., Tech. Paper* No. **17**, 23 pp.(1939); cf. *C. A.* **33**, 2740[9], 2742[7], 9686[3].—Lac-ethylene glycol ether (I) was prepd. by heating 62 g. of ethylene glycol to 130–140° and gradually dissolving 100 g. of lac in it (10 1 mol. ratio). After a reaction period of 15 min., 0.5% of *p*-toluenesulfonic acid was added as a catalyst. After heating for 1 hr. the end of the reaction was indicated by a tendency to gelation. Analysis of the final product indicated that 4 mols. of ethylene glycol had reacted with 4 OH groups contained in 1 mol. of lac, forming a monoether (theoretical mol. wt 1176, mol. wt. calcd. from the observed acid value 1233). The product was a sticky material which became brittle in storage. In its unpolymerized state it was sol. in all common solvents but films produced from the solns. were unsatisfactory. I was prepd. at a higher temp. by heating 500 g. of lac and 186 g. of ethylene glycol (1.6 mol. ratio) at 120° until the former dissolved, cooling to 80° and then adding 1 cc. of concd. H_2SO_4 as a catalyst. Vigorous reaction took place with much frothing and some carbonization. The mixt. was then heated at 180–190° in a flask equipped with a long air condenser. The acid value became const. after heating for 2.5 hrs. The mixt. was poured into H_2O and the excess glycol was removed by repeated washing with boiling H_2O. The product was dried under vacuum on a water bath. It had the following characteristics: acid value 22.8, sapon. value 182.4, ester no. 159.6, OH no. 202.4, I no. (Wijs) 43.4 and mol. wt. calcd. from acid value 2461 (theoretical 2422). Apparently 5 mols. of ethylene glycol had combined with 1 mol. of lac to form I, which is considered to be a dimer. By drying the washed reaction product at atm. pressure instead of under vacuum a trimer was obtained. This had acid value 13.4, sapon. value 199.9, ester no. 186.5, OH no. 199.9 and mol. wt. 4186 (theoretical 3624). All products of I were sticky balsams which did not change consistency in storage. They were completely sol. in MeOH, BuOH, BuOAc, Me_2CO, MeCOEt, methylcyclohexanone and cyclohexanone, but were insol. in cyclohexane, white spirit, solvent naphtha and drying oils. They could be polymerized by heat to tough, flexible rubber-like materials which lost their solv. in the above solvents but swelled in methylcyclohexanone. The solns. possessed lower viscosities than corresponding solns. of lac and they could be incorporated into nitrocellulose lacquers. As much as 7 parts of I was added to 1 part of nitrocellulose and produced a clear hard film. The viscosities, drying time and film properties of 4 typical solns are tabulated. I was esterified with crotonic acid (II) and with cinnamic acid (III) by refluxing the dimer with 5 different ratios of the individual acids at 170–180°, with and without catalysts. A greater degree of esterification was obtained when catalysts were used. High acid values and low mol. wts. of some of these compds. indicated that monomers were formed with II and dimers with III. The

characteristics of 11 of these products are given. In the unpolymerized state the products from II and III were sol. in most solvents. Films on glass, Sn and Cu prepd. from PhMe soln. had excellent adhesion and flexibility when air-dried or baked. Detached films were prepd. on Sn amalgam and had good flexibility, high tensile strength and the silkiness of tung oil varnish. An excess of Co drier produced a wrinkle effect. The films from II and III behaved like those produced from oil varnishes. The polymerization of I, II and III is discussed from a theoretical standpoint and the following applications are suggested: *elec. insulating materials* which withstand the action of O_3; *rubber-like products; impregnating and coating agents for textiles*, including antigas and parachute fabrics; *paints* for elastic surfaces; *plasticizers;* and special *adhesives*. 18 references. L. Wilson Greene

Iodine values of lac. Reaction between halogen and lac. B. S. Gidvani and R. Bhattacharya. *London Shellac Research Bur., Bull.* No. 3, 13 pp.(1939); cf. Karim and Cook, *C. A.* **33**, 2742[3]. I nos. of lac and lac esters were detd. by using the Langmuir modification of the Wijs procedure (I) (*J. Soc. Chem. Ind.* **24**, 12(1905); *C. A.* **5**, 3629) and the standard Hübl method (II). An addn. of halogen and simultaneous oxidation take place with I but only an addn. occurs with II. The increased I no. obtained on prolonged contact in both methods is not caused by deterioration of the reagents. The accepted I nos. of shellac (Wijs 14–18, Hubl 7–9) do not give a quant. measure of unsatn. but are arbitrary values detd. by certain specified conditions. Consistent results can be obtained as long as the conditions are kept const. II gives fairly reliable results since it is practically independent of time of contact, concn. of available halogen and temp. In I these factors have to be controlled accurately to give dependable results. A slight variation in any of these factors (e. g., use of glacial HOAc instead of 99%, or a higher temp. than 22 ± 1°) leads to inconsistent values. 25 references. L. Wilson Greene

Methods of preparation of alkyd lacquers. R. D. Samyslov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 236–7(1939). A general discussion. Chas. Blanc

Cellulose derivatives in lacquers. C. Maters. *Official Digest Federation Paint & Varnish Production Clubs* No. 190, 390–8(1939).—See *C. A.* **34**, 648[3]. H. M. S.

The rate of lacquer aging. V. S. Kiselev, K. F. Efimova and V. Ya. Solonina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 490–4(1939).—From a review of literature and exptl. evidence it is concluded that the basic processes of aging and settling of oil paints made with resinates and Albertol and Glyptal resins are completed in the 1st month of storage. In most cases the sediments of suitably prepd. lacquers can be removed by filtering or centrifuging without the dangers of new sedimentation in the next 20–30 days and impairment of the coating and tech. properties of lacquers. The aging properties of resinate and alkyd lacquers are compared with paints made with copals in relation to the various factors of temp. of prepn. and storing, compn., degree of oil polymerization, etc., which influence the aging process and quality of paints and lacquers. Thirty references. Chas. Blanc

Water as a component part in simple nitrocellulose varnishes. N. V. Aleksandrov and G. S. Plotnikova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 325–6(1939).—It is shown that the content of water in nitrocellulose varnishes can be increased to 10% on the vol. of the volatile ingredients (100% on the wt. of nitrocellulose) in the presence of EtOH without the use of cellosolve or mixts. of AcMe and MeOH. The resulting films compare favorably with anhydrous lacquers. The varnishes were prepd. from colloxylin 5, dibutyl phthalate 0–0.9, AcOBu (b. 116–35°) 29.45–40.37, BuOH (b. 110–22°) 7.2–10.45, EtOH 26.12–28.23, aviation gasoline (d_4^{17} 0.735, b. 62–134°) 9.5–24.1 and water 4.75–9.5%. Chas. Blanc

Determination of the tackiness of oil and lacquer films. I. I. Golovistikov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 461–2 (1939).—The stickiness of dry oil films is a function of the relative gliding friction which is derived from the angle at which a cloth-covered metal plate slides from a glass plate coated with the oil or lacquer to be tested and dried at room temp. for 5 days. The procedure is described in detail. Chas. Blanc

Electrical method of measuring the thickness of thick cellulose films with special application to the "hot lacquer" process. G. H. Stephenson. *J. Sci. Instruments* **16**, 378–9(1939).—Properties of the films as the dielectric of a condenser are sufficiently stable and suitable to permit detg. their thickness from the measured capacity over a given surface area. A direct-reading arrangement using a special-type valve voltmeter is described and illustrated. M. McMahon

New zinc resinates in protective coatings. Edwin Edelstein. *Official Digest Federation Paint & Varnish Production Clubs* No. 190, 398–408(1939); cf. *C. A.* **33**, 8427[7].—A review of the uses and advantages of zinc resinates (Zitro and Zirex) in ester gum and phenolic varnishes, in thixotropic enamels, in alkyd blends and in blends with ethylcellulose. H. M. Stark

Mold discoloration. W. P. K. Findlay. *Paint Manuf.* **10**, 37–8(1940).—A summary. A paper dealing with mold growth on oil-painted surfaces. White lead and lithopone are quite susceptible to mold growth. Linseed oil or other drying oil is a good food for molds and the presence of foots or traces of nitrogenous matter increases the tendency to growth. Stand oils are superior to raw or boiled oils. Materials which have an inhibiting effect in agar medium do not necessarily function in oil. Infection takes place during the "tacky" period of paint-film drying. Two methods of testing the efficiency of antiseptic materials were: (1) small blocks of wood are dipped in the paint and allowed to drain and before they are hard dry the surfaces are infected and the blocks held at 22° for 2–3 months and (2) disks of mech. wood pulp soaked in 2% malt soln. are infected and the paints applied over the damp surface. The effect of an added antiseptic in paint is important. It must not affect the drying and any alk. reaction must be avoided. Field tests are necessary to det. definitely the usefulness of fungicidal paints. W. H. Boynton

Utilization of seed of *Plantago psyllium* [oil for prepn. of varnishes] (Bottini) **27**. Comparative evaluation of qualities of white pigments for coating leather (Zel'din, Chumakova) **29**. Electrolytic oxidation of white ferrous ferrocyanide in production of Prussian blue (Belen'kiĭ, Vorontsov) **4**. Infrared absorption spectra of drying oils (Gamble, Barnett) **3**. Synthetic leather-resinous compn. for lacquer manuf. (U. S. pat. 2,184,467) **13**. Basic sulfamate of quadrivalent Ti [for pigments] (U. S. pat. 2,184,538) **23**.

Paint suitable for use without a primer. Frank A. Strauss (to Wailes Dove-Hermiston Corp.). U. S. 2,184,324, Dec. 26. A mixt. is used contg. a liquid vehicle, such as one of drying oils, etc., which forms a relatively hard permanent film, flakes of metal such as Al coated with a leafing agent that float from a film of the freshly applied paint to form a substantially continuous layer of oriented overlapping flakes, and a nonmetallic corrosion-inhibiting pigment such as Pb_3O_4 or ZnO, which remains dispersed in the film from which the metal flakes float (the proportion of such pigment being about 15% or less of the wt. of the metal flakes).

Oil paint suitable for use on wet surfaces. Herman A. Scholz (to United States Gypsum Co.). U. S. 2,183,227, Dec. 12. A water-in-oil stable homogeneous paint emulsion contains a minor amt. of water, a major amt. of a drying oil, a pigment such as lithopone or an Fe oxide, and a Zn compd. such as ZnO, leaded ZnO, $Zn(OH)_2$ or $ZnCO_3$ to maintain the ingredients in stable condition.

Water colors. I. G. Farbenindustrie Akt.-Ges. Ger. 684,820 Dec. 6, 1939 (Cl. 22g. 2.01). The binding material of a water-color paint is a water-sol. polyvinyl ether or water-sol. mixed polymers from vinyl ethers together with water-insol. vinyl ethers or other water-insoluble vinyl compds.

Titanium pigments. E. I. du Pont de Nemours & Co.

Brit. 508,530, July 3, 1939. The wet grinding process for the production of TiO_2 pigments is improved to produce pigments of fine texture, readily incorporable in paint and enamel vehicles and of low sensitivity to H_2O, by grinding the calcined pigment in the presence of a relatively small proportion, e. g., 0.05–2%, of 1 or more aluminates of an alkali metal, e. g., of Na, Li or K, which may be added dry before the addn. of H_2O or added as a soln. The grinding may take place in a closed circuit with 0.1–0.7% of the aluminate(s).

Pigment chip compositions. David R. Wiggam (to Hercules Powder Co.). U. S. 2,184,539, Dec. 26. A mixt. that is substantially nonvolatile at normal room temps., that requires a milling temp. above about 100° to effect colloiding and contains, ethylcellulose and a pigment within the range of about 40–90%, of the max. amt. that can be dispersed in the ethylcellulose as detd. by a shortness of bead is milled at the temp. at which the ethylcellulose is colloided, about 100–150°, to effect uniform dispersion of the pigment throughout the ethylcellulose colloid.

Drying oils. Koninklijke Industrieele Maatschappij voorheen Noury & van der Lande N. V. Brit. 508,516, July 3, 1939. Drying oils are manufd. from oils having 1 or more OH groups in the fatty acid radical, e. g., castor oil, by heating the oils substantially above 150°, e. g., to 180–240°, to split off H_2O from the fatty acid radical, in the presence of a small proportion, e. g., 0.1–1%, of a catalyst consisting of 1 or more H_2SO_4 derivs. having oxidizing properties, e. g., SO_3, fuming H_2SO_4, $H_2S_2O_7$, $H_2S_2O_8$ or monopersulfuric acid or such salts derived from these acids as have oxidizing properties, e. g., K, Na or NH_4 persulfate, or such reaction products of these acids on oils with OH groups in the fatty acid radicals as have oxidizing properties. Cf. *C. A.* **33**, 1974[5].

Drying oil from castor oil. Koninklijke Industrieele Maatschappij voorheen Noury & van der Lande N. V. Dutch 47,417, Dec. 15, 1939. Sulfonated lower aliphatic hydrocarbons added to castor oil in the amt. of 0.01–0.001% produce a drying oil of negligible color. The water is liberated at a temp. of 170°; the reaction takes place readily at 180–200° and is finished at 250°. Particularly valuable catalyzers are mono-, di-, tri- and polysulfonic acids of methane, especially methionic acid. The oil obtained has a high acid no. especially if the oil is finished to stand oil by heating above 250°. This tendency can be corrected by adding sufficient polyhydric alc. prior to heating.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The fats of marine algae. V. Nonvolatile fat acids of Alaria crassifolia Kjellm. Eizi Takahasi, Kiyosi Sirahama and Nobuhisa Togasawa. *J. Chem. Soc. Japan* **60**, 56–60(1939); cf. *C. A.* **32**, 8809[4]; **33**, 4201.—The thallus (I) contains 23.22% solid and 76.78% liquid fat acids. Of the solid acids 80% is $C_{16}H_{32}O_2$ and 20% $C_{14}H_{28}O_2$. From the liquid acids were obtained 4% $C_{16}H_{30}O_2$, 12% $C_{16}H_{28}O_2$, 11% $C_{18}H_{32}O_2$, 3% $C_{18}H_{30}O_2$, 19% $C_{18}H_{28}O_2$. The fructification (II) contains 51.02% solid and 48.98% liquid fat acids. Of solid acid 80% is $C_{16}H_{32}O_2$ and 20% $C_{14}H_{28}O_2$. From the liquid acids were obtained 5% $C_{16}H_{30}O_2$, 12% $C_{16}H_{28}O_2$, 17% $C_{18}H_{42}O_2$, 3% $C_{18}H_{30}O_2$, and 5% $C_{18}H_{28}O_2$ I, in which assimilation takes place, contains more unsatd. acids and II, which functions as storage, contains more satd. acids. As in other marine sea algae, palmitic and myristic acids are found, but not stearic acid. I and II were sepd., dried first in the sun then at 70–80°, extd. with 80–90% alc., mannitol and other impurities pptd. on cooling were removed, the alc. soln. was extd. with ether, the ether soln. dried, and extd. with acetone, the acetone ext. shaken with petr. ether after addn. of water. Evapn. gave 1.06% crude fat for I and 0.97% for II. The fat is sapond. with 10% alc. KOH, the fat acid dissolved in hot 95% alc. and treated with hot 95% alc. soln. of lead acetate, let stand overnight, and filtered. Solid fat acid was obtained from the ppt. by decompn. in water with HCl and extn. with ether. Liquid fat acid was obtained from the soln. by a similar method after evapn. of the alc. The solid acid was fractionated by recrystn. from MeOH. The liquid fatty acid was decolorized by norite, brominated in ice-cooled ether, the ppt. sepd., the soln. treated with petr. ether to sep. the sol. (dibromo) and insol. (tetrabromo) portions. The ppt. was treated with benzene to sep. the sol. (hexabromo) and insol. (polybromo) portions. The acids were identified by debromination with glacial AcOH and Zn powder, and detn. of neutralization nos., mol. wts., iodine nos., n^{25}_D, hydrogenation, and acetone-soly. of the Li salts.
K. Shinohara

Chemical investigation on Callistemon (Myrtaceae). I. Fat extracted from the berries. Federico Sallusto. *Ann. ist. super. agrar. Portici* **8**, 41–7(1936–37).—Berries from *Callistemon lanceolatum* contained H_2O (at 100–105°) 51.49, fat (Et_2O ext.) 5.39, nitrogenous matter (N × 6.25) 2.97, crude fiber 14.63, ash 5.58, nonnitrogenous ext. (by difference) 19.94, reducing sugars 0.84, tannic substances 13.47, sol. matter (ext.) 16.55, ash of the ext. 1.95 and alc.-sol. matter 28.15%. The oil, freed from resin, gave d_{15} 0.9475, d_{98-100} 0.8640, refractometric degree at 40°, 47–53°, m. p. of fat 40–52°, m. p. of fatty acids 61–67°, solidification point of fat 37–43°, solidification point of fatty acids 56–63°, acidity as oleic acid 23.70%, Kottstorfer no. 186.12, ether no. 99.10, Hehner no. 79.71, Reichert-Meissl no. 8.20, acetyl no. 23.26, relative I no. 34.18, abs. I no. 97.98, fat 96.30%, nonfat 3.70%, unsaponifiable 15.55% and Polenske no. 6.17. The solid fatty acids consisted of palmitic 15.58 and stearic 84.42% and the liquid fatty acids of oleic 54.25, linolic 3.87 and linolenic 41.88%.
A. R. Merz

Some color reactions for the detection of extracted cacao-waste fats. K. H. Bauer and L. Seber. *Kazett* **27**, 340–2(1938); *Chem. Zentr.* **1938, II**, 3481–2; cf. *C. A* **33**, 5212[8], 5213[2].—Color reactions investigated were those of concd. H_2SO_4 on a soln. of the fat in $CHCl_3$, of fuming HCl and HNO_3 on the heated fat, of 50% H_2SO_4 on the fat after it has been heated with Ac_2O, and of glacial HOAc on the melted fat (on the boiling water bath). Definite colors which would indicate with certainty the presence of extd. fat were observed only in the case of extd. fats having a content of 1.2–2.0% unsaponifiable matter. In the case of mixts. of extd. waste fat with press butter in which the content of the mixt. in unsaponifiable matter was 0.6–0.7% it was not possible to detect with certainty the presence of the extd. fat by the use of the color reactions tested.
M. G. Moore

Determination of fat by the Grossfield method. W. H. Kitto. *Analyst* **65**, 07(1940).—Grossfield's method has received considerable attention in recent German literature. A comparison of the results with those obtained by Soxhlet extn. shows very serious discrepancies. The values obtained by G.'s method were much higher and the dried fats were much darker. Thus with 2 samples of corn meal, Soxhlet extn. gave values 1.2 and 4.2, whereas G.'s method showed 2.2 and 6.2, resp. The question arises as to whether rubber stoppers are not affected by trichloroethylene more than has been supposed.
W. T. H.

The changes in the coefficients of refraction during the process of hydrogenation of vegetable oils. G. B. Ravich. *J. Tech. Phys.* (U. S. S. R.) **7**, 2249–54 (1937); *Chem. Zentr.* **1938, II**, 3480.—Changes in n^{25}_D, the viscosity, d. and solidification temp. of the fat acids with the degree of hydrogenation of cottonseed oil and of sunflower-seed oil were followed. Hydrogenation increased the viscosity but decreased the d. and n^{25}_D. For a series of oils the I no. showed a linear relation to n^{25}_D. For cot-

tonseed oil the relation is expressed by $n_D^{25} = 1.4551 + 0.00012$ (I no.) and for sunflower seed oil by $n_D^{25} = 1.4491 + 0.00016$ (I no.). The relation between the viscosity and I no. for these oils is practically linear. M. G. M.

The quality of the oils in relation to the maturation of the olives. Federico Sallusto. *Ann. ist. super. agrar. Portici* 8, 34–40(1936–37).—Olives gathered at various stages from the green immature to completely mature states showed a progressive decrease in H_2O content of the pulp from 68.5 to 46.8–48.2% and an increase in ethereal ext. from 24.75 to 33.58% and in reducing sugars (on the dry basis of the pulp) from 1.97 to 3.80%. Reducing sugars after inversion totaled 5.45, 5.19, 6.05, 5.82, 4.90, 6.24 and 5.77% at the different states of maturity. Sp. gr., free acid (as oleic), sapon. no., relative I no., abs. I no., liquid fatty acids, solid fatty acids, index of refraction, thermosulfuric index and viscosity at 15° values are tabulated for the oils. Not only is the oil obtained from completely mature olives not inferior than that obtained from immature olives but the chem. compn. of the oils vary but little in the course of maturation. A. R. Merz

The oils of Gargano. F. Sallusto and A. Centulio. *Ann. ist. super. agrar. Portici* 8, 69–94(1936–37).—The sp. gr., refractometric index, viscosity, acidity, sapon. no. and I no. are given in tables for 46 olive oils from the Gargano promontory. A. R. Merz

Hull control in the production of mustard oil. A. Katsman and S. Elchenko. *Maslobo'no Zhirovoe Delo* 13, No. 5, 22–3(1937); *Chem. Zentr.* 1938, I, 4249.—The difference in d. between the hulls and kernels of mustard seeds is not great enough to serve for the detn. of the hull content of such a mixt. The crude-fiber content of the hulls is 23–7.6%, that of the kernels only 2.79–2.89%. This difference is sufficient to permit the detn. of the hull content of a mixt. with an accuracy of 1.5%. The method however, is cumbersome. Jeltschenko gives a method for the direct sepn. of the hulls. After removal of the fat, the kernels consist predominantly of proteins partially sol. in water, salt solns. and weak alkalies. The hulls, freed from the kernels, sink to the bottom in such solns. After removal of fat, the powder, oil cake, etc., are ground to meal and screened. Then 0.8–1.0 g. of the meal is allowed to stand 1 hr. in 25 cc. alc., 800–50 cc. of water is added and the whole well stirred. After 3–5 min. the particles of hull sink to the bottom while the emulsion of the kernel proteins remains suspended. The operation is repeated 5 times. Then the hulls are shaken for 15 min. with 100 cc. 2% NaOH. The NaOH soln. is poured off, the hulls washed with 800–50 cc. of water, filtered, washed on the filter with water, alc. and ether and dried at 150°. M. G. Moore

Seed oils of Formosan plants. XVI. Seed oil of Litsea cubeba Pers. Tyuta Hata. *J. Chem. Soc. Japan* 60, 122–5(1939); cf. *C. A.* 33, 1977[5].—Ether extn. gave 44% of fatty substance, solid below 30°, the seeds of *Litsea cubeba* Pers. Steam-distn. of this ext. gave 3.1% of almost colorless volatile oil, consisting mainly of a mixt. of about equal amts. of citral and methylheptenone. The fatty substance from which volatile oil had been removed contained 1.3% unsaponifiable matter, from which 3.5% sitosterol was isolated as digitonide. Other constituents of the unsaponifiable matter are unknown. The fat acid mixt. was methylated and fractionally distd. The constituents of the acid mixt. are lauric 53.2, capric 22.9, myristic 4.5, unsatd. acids 19.6%. Linderic, tetradecenic, oleic and linolic acids were the main unsatd. constituents. A minute amt. of hexadecenic acid is probably present. K. Shinohara

Utilization of the seed of Plantago psyllium L. Ottaviano Bottini. *Ann. ist. super. agrar. Portici* 9, 75–82 (1937–38).—The seed contained H_2O 13.20, mucilage 10.34, crude fat 6.14, crude protein 7.68, nonnitrogenous ext. (less mucilage) 52.08, cellulose 7.64 and crude ash 2.92%. The mucilage may in some cases be used in place of gum arabic, especially for *dye printing*. The oil, extd. from the mucilage-freed seed, had d_{15} 0.924, solidification point −17°, n_{25} 73.2°, thermosulfuric acid test 78, free acids (as oleic acid) 5.04%, sapon. no. 191 and ether no. 181, sol. acids (as butyric acid) 0.82%, insol. acids 94%, R. M. W. no. 1.94, Polenske no. 7.67, I no. 124 and unsaponifiable 1.21%. It may be used for the prepn. of *varnishes* in mixt. with linseed oil. The residue from the oil extn. may be used as a *feed*. A. R. Merz

Constituents of bonito oil. IV. Liquid acids (2). Sumio Matuda and Sei-iti Ueno. *J. Chem. Soc. Japan.* 60, 49–55(1939); cf. *C. A.* 33, 1978[2].—A mixt. of fat acid esters obtained from bonito oil was fractionated by distn. at 5 mm. Hg. Sapon. of the fraction b. 205–13° gave a mixt. of C_{20} acids; these were sepd. by treatment of the Na salts with acetone, the Li salts with alc., and the Pb salts with alc. into gadoleic, eicosatetraenic and eicosapentaenic acids. From distillates described in the previous report was obtained by further fractional distn., sapon. repeated distn. of remethylated acid, and resapon. a mixt. of C_{22} acids. From this mixt. were isolated cetoleic acid, $C_{22}H_{42}O_2$, docosapentaenic acid, $C_{22}H_{34}O_2$, and docosahexaenic acid, $C_{22}H_{32}O_2$. From the Me ester fraction b_1 212–16° was obtained a mixt. of C_{24} acids; this mixt. fractionated by the Li salt-acetone method yielded a new acid, *bonitonic acid*, not obtained pure, corresponding in acid no. and I no. to $C_{24}H_{34}O_2$. K. Shinohara

The composition of the antarctic seal oil. Sei-iti Ueno and Masayosi Iwai. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 371–3(1939).—Antarctic seal oil (from the skin) is a pale yellow liquid having: d_4^{15} 0.9286; n_D^{25} 1.4814; acid value 0.41; Wijs I value 164.7; sapon. value 194.3; and unsaponifiable matter 0.25%. Tests on the mixed fatty acids were: d_4^{15} 0.9099; n_D^{25} 1.4698; Et_2O-insol. polybromide 37.90%; neutralization value 197.8; I value 166.8; percentage of Br in polybromide 70.70; liquid acids (Pb salt-alc. method) 90%. Fractionation of the Me esters of the mixed fatty acids showed that (1) the solid acids were chiefly palmitic acid, with small amts. of stearic and myristic acids, and (2) besides the ordinary unsatd. acids ($C_{16}H_{30}O_2$, oleic acid, $C_{20}H_{38}O_2$, etc.), large quantities of highly unsatd. acids were present, such as clupanodonic acid ($C_{22}H_{34}O_2$) and possibly scoliodonic acid ($C_{24}H_{36}O_2$) and nisinic acid ($C_{24}H_{36}O_2$). Cholesterol was isolated from the unsaponifiable matter. G. Ayers

The Twitchell process. J. H. Wigner. *Soap, Perfumery & Cosmetics* 12, 979–84,992(1939).—Small plant equipment, method of operation and operating results on several oils are presented. M. M. Piskur

Steam distillation of glycerol under reduced pressure. I. Distilled quantity and quality of glycerol prepared from saponification crude glycerol, soap lye crude glycerol and recovered glycerol. Sei-iti Ueno and Tiduo Yonese. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 342–5(1939). —By use of the app. of Iwai and Ueno (*C. A.* 32, 1962[8]), sapon. crude glycerol, soap lye crude glycerol and recovered crude glycerol (analyses, resp., were: percentages of glycerol, 86.94, 83.19, 81.09–74.17; d_4^{15} 1.229, 1.298, 1.320–1.317; n_D^{15} 1.4570, 1.4718, 1.4729–1.4747; percentages of evapn. residue at 160°, —, 10.7, 14.9–24.2; percentages of NaCl, 1.3, 8.0, 6.6–6.2; color, pale yellowish brown, reddish brown, brownish black) when distd. at 6.0–8.3 kg./sq. cm. steam pressure (steam temp. 200–280° and under 45.5–88.5 mm. at 156–166° yielded, resp., 857, 701 and 536 kg. of product having the following properties: percentages of glycerol, 95–98, 94–97, 92–95; color, none, pale yellow, pale yellow. **II. Steam requirements in the saturated steam and superheated steam distillations of saponification crude glycerol and soap-lye crude glycerol.** *Ibid.* 346–50.—For the production of 100 kg. of glycerol by steam distn. of sapon. crude glycerol and soap-lye crude glycerol, the av. steam consumption was, resp., (kg.): superheated steam distn., 530, 650; satd. steam distn., 948, 1410. George Ayers

History of the manufacture of soap. F. W. Gibbs. *Ann. Sci.* 4, 169–90(1939). C. L. B.

The Japanese soap industry. N. N. Godbole. *Soap, Perfumery & Cosmetics* 12, 663–5(1939).—Import duties on soap and soap raw materials, and production, exports and imports from 1911 to 1937 are given. M. M. P.

Milk and protein soaps. Josef Augustin. *Soap, Per-*

fumery & Cosmetics **12**, 586–8, 618(1939).—Formulas. M. M. Piskur

Fatty acids and their application in soaps and cosmetics. Archibald Rayner. *Soap, Perfumery & Cosmetics* **12**, 898–900, 902(1939). M. M. Piskur

Resistant high colloids for soaps, creams, greases and finishes. L. Zakarias. *Soap, Perfumery & Cosmetics* **12**, 850–2(1939).—The advantages of using "collectons" in soaps and cosmetics are discussed. "Collectons" are said to be manufd. from colloids having a polysaccharide base. Method of manuf. is not given. M. M. P.

Tetrasodium pyrophosphate and its application in the soap and allied industries. Joseph M. Vallance. *Soap, Perfumery & Cosmetics* **12**, 765–6(1939). M. M. P.

Analysis of soap stock. M. Z. Klyachko. *Maslobo˘ino Zhirovœ Delo* **13**, No. 5, 21(1937); *Chem. Zentr.* **1938, I**, 4251.—In a porcelain dish 10 cm. in diam. 3–4 g. of the soap stock is treated dropwise with H_2SO_4 (1:4) or HCl (1:1) in the presence of methyl orange until the reaction is faintly acid. The mass is then well stirred and Na_2SO_4 added at 60–70°. The powdery mass so formed is then extd. with ether or petroleum ether and the oil titrated in the usual manner. W. A. Moore

The presence of air in soap. J. H. Wigner. *Soap, Perfumery & Cosmetics* **12**, 751–2, 780(1939).—Apart from floating soaps, com. soaps are generally assumed to be free from air. Air may have an undesirable effect on texture. Its effect on sp. gr. requires continual readjustment of the cutting wires and it may cause trouble in packing. The increase in viscosity due to air will cause soap to flow slowly through chutes and conduits. If this happens a test for air should be made. Retention of air may occur in faulty treatment of liquid soap. Pumps may be the cause or the trouble may occur in the crutcher. The later can be obviated by adjusting the mixing blades to prevent splashing. M. M. Piskur

Choice of soap for emulsified creosote disinfectants. R. L. Datta, S. C. Sen and N. N. Bose. *Soap, Perfumery & Cosmetics* **12**, 583–5(1939).—Highest activity is displayed for emulsion formation when the hardness no. of the soap is between 125 and 140. With soaps contg. rosin the optimum hardness no. appears to lie near 125. The best results are obtained with a blended soap made from oil stock contg. 50% castor oil. This is possibly due to the presence of the hydroxy fat acid. Some addn. of rosin (10 to 15%) in making the soap is important as it favors emulsion formation at high dilns. M. M. Piskur

Outline of methods for preventing spoilage. E. Pannewitz. *Seifensieder-Ztg.* **67**, 18, 28, 47–8(1940).—References are given to patents covering methods of combatting attacks by bacteria, molds, insects, etc. Brief lists of pests are included. A. Guillaudeu

Testing wax mixts. for use in plant propagation (Shelton) **11D**. Swedish pine needle oil and its components (Sandermann) **17**. Proximate analysis of Brit. Columbia herring in relation to season and condition factor [oil from] (Hart, *et al.*) **12**. Eleven years of soybean investigations [oil content] (Van Doren, Hackleman) **12**.

Apparatus for use of solvents in extracting oils, fats and other soluble constituents from solid materials. Michele Bonotto (to Extractol Process, Ltd.). U. S. 2,184,248, Dec. 19. Various structural and operative details.

Distillation of mixtures of high boiling point such as fatty acids of vegetable and animal oils and fats. Otto Brücke (to American Lurgi Corp.). U. S. 2,184,579, Dec. 26. An arrangement of app. is described and a method for the continuous distn. of mixts. of a plurality of substances which have different b. ps., in at least two serially arranged vaporization stages, which comprises forcing up the mixt. to be distd. from the liquid space into the vapor space of the distg. vessel in every stage, constantly diverting a portion of the forced-up liquid without intermingling with the liquid remaining in the liquid space into the next still, separately condensing the distillate vapors obtained in each still, and adjusting the vaporization temps. in the various vaporization stages to different values for the purpose of continuously extg. the distillates in two or more fractions. Cf. *C. A.* **34**, 1519⁵.

Purifying oils containing fatty acids. Ivor M. Colbeth (to Baker Castor Oil Co.). U. S. 2,183,486, Dec. 12. App. is described, and a process of purifying an oil such as castor oil contg. fatty acids, which involves passing an aq. alk. soln. such as a NaOH soln. downwardly through a confined space at a rate slower than drops of the oil will rise through it, introducing the oil into the lower portion of the space and dividing it into droplets without agitating it or causing it to form a stable emulsion while dissolving the resulting soap in the liquid phase of the soln. for removal.

Aliphatic acid esters of alkylol ethers of β-hydroxyalkyl- and β-hydroxycyclo-alkyl ethers of the dibenzanthrone and isodibenzanthrone series. Otto Stallmann (to E. I. du Pont de Nemours & Co.). U. S. 2,183,629, Dec. 19. Dibenzanthrone and isodibenzanthrone alkylene oxide ether derivs. are esterified with aliphatic acid chlorides or anhydrides to give aliphatic ester ether derivs. which are very sol. in oils, fats, waxes and inert org. solvents, such as benzene, toluene, xylene, etc., and which are suitable *for the coloring of oils, fats, waxes, plastic masses, cellulose compds.*, etc., for which purpose the original vat dyes as such are not suitable and for which the unesterified alkylol ethers do not give the desirable strong coloration. All of these ester-ether derivs. of the dibenzanthrone and isodibenzanthrone series are insol. in water and stable under ordinary conditions. They are unstable in concd. H_2SO_4 and are sapond. when treated with alc. caustic or strong alk. hydrosulfite solns. at high temps. When dissolved in org. solvents and other materials, they all show a very strong and desirable fluorescence ranging from a bright greenish yellow through orange and red to brown. Various examples with details are given. U. S. 2,183,630 relates to production of compds. such as the laurate of the mono-(β-hydroxycyclohexyl) ether of *Bz*-2, *Bz*-2′-dihydroxydibenzanthrone, a blue colored solid which is highly sol. in oil, gasoline, acetone, cellulose acetate and many plastic masses and artificial resins, imparting to these materials a very strong and bright blue coloration in transmitted light, exhibiting a strong reddish fluorescence in reflected light.

Extraction of oils such as soybean, castor, whale, cod-liver and halibut oils. Alan G. Hamilton and Ezra C. Perkins (to E. I. du Pont de Nemours & Co.). U. S. 2,183,837, Dec. 19. App. is described, and a continuous process for extg. extractable material from solids wherein a solvent for the extractable material flows countercurrent to the direction of travel of the solids through the solvent, which comprises continuously passing the solid through a countercurrent stream of the solvent under conditions wherein extn. is carried out under pulsating pressures.

Improvement of soaps or fatty acids. I. G. Farbenindustrie Akt.-Ges. (Max Harder, inventor). Ger. 684,968, Dec. 8, 1939 (Cl 23*e*. 1). The soaps formed from oxidation products of high-mol. nonaromatic hydrocarbons are heated under pressure with an equal wt. of H_2O or more. Then the pressure is released in stages.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Raw-sugar clarification. J. G. Davies. *Intern. Sugar J.* **41**, 463–5(1939); cf. *C. A.* **33**, 7139⁸.—High- and low-clarifiability juices were examd. for (1) org. colloids, (2) ash phosphates, and (3) silica. The only significant difference was in the silica content, and evidence shows this to be a contributing factor in clarifiability. The

fractional liming and double heating process (*C. A.* **31**, 567[8]) is recommended. D. P. Langlois

Storage of sugar. E. R. Behne. *Intern. Sugar J.* **42**, 15(1940).—In Java large quantities of sugar were successfully stored for protracted periods. Investigation of the factors governing the hygroscopicity of sugar-house products and of raw sugars shows that for a sugar with a given diln. indicator there is a corresponding value of the relative humidity of the air which will be in equil. with this sugar. The limiting factor for the diln. indicator is 50 for abs. safety, the range from 50 to 100 being doubtful; with values above 100 deterioration is almost certain. General observations on deterioration and its prevention are: The sugar should be bagged with as low a moisture content as possible and not too hot. The bottom and top of the stack should be well insulated with waterproof material and the stacks should be large, leaving as little surface exposed as possible. Fine grain should also be avoided. D. P. Langlois

Possibility of reducing the lime salts in sugar juices, with a rise in the purity. J. Zamaron. *Bull. assoc. chim.* **56**, 709-23(1939).—Lab. and factory expts. during 4 campaigns have shown that as much as 79% of the Ca salts can be removed by treating 2nd carbonatation juice at 90° first with $(NH_4)_2HPO_4$ or Na_2HPO_4 and then with $BaAlO_4$ or Na "phosphoaluminate" (compn. not given), and filtering after each treatment. The phosphate and aluminate may also be added at one time. The reagents remove other impurities also by chem. action or adsorption, and increase the purity from 0.5 to over 2 points. More and better sugar is obtained, the molasses production is reduced, there is less scale in evaporators and pans, and the color of the products is improved. The detailed results are shown in tables and graphs. F. W. Z.

Automatic-optimum deliming of sugar juices. W. Reischauer. *Centr. Zuckerind.* **47**, 1110-11(1939).—Optimum alky. and the best possible deliming were obtained in an automatic air-stirred satn. vessel. W. W. Binkley

Juice discoloration during evaporation. Fr. Janák. *Deut. Zuckerind.* **64**, 1101(1939); cf. *C. A.* **33**, 5217[8].—Discoloration of juices can usually be traced to too high evapn. temp., but long heating below 100° has the same effect. At a fixed pH there exists a math. relation between discoloration and the product of temp. and time. Discoloration is impeded by electrolytes, e. g., H_2SO_3. Color formation is reduced about 80% when active C is used under its isoelec.-point conditions. W. W. B.

Comparative chemical compositions of juices of different varieties of Louisiana sugar cane. C. A. Fort and Nelson McKaig, Jr. *U. S. Dept. Agr., Tech. Bull.* 688, 68 pp.(1939).—Apparent and true solids, apparent and true sucrose, acidity, pH value, reducing sugars, ash, Si, Ca, K, Na, Mg, Al, Fe, Mn, S, Cl, P, total and protein N and gums were detd. in the crusher juices of 8 varieties of sugar cane grown on different soils in La. Calcd. values are given for total nonsucrose, true and apparent purity, approx. org. acids, nonprotein N and salts. A variety of sugar cane grown under identical conditions always shows the same relative content of the various nonsugar substances. Different varieties under uniform conditions not only produce definite comparative tonnages of cane and percentages of sugar and fiber, but also definite comparative quantities of other constituents such as acids, CaO, K_2O, P_2O_5 and N. The actual quantities may be large at one location and small at another but the comparison between the varieties will be much the same. On account of the differing nonsugar characteristics of the various sugar-cane varieties, all studies to det. the effect of soil, climate or other factors should use the same varieties. 64 references. W. H. Ross

Experiences with the refining of cane sugar. Felix Langen. *Centr. Zuckerind.* **47**, 1107-10(1939).—The cooking period of 70% clarified juices was shortened by approx. one half and the yield of (sugar) press cake almost doubled when the treatment with boneblack was omitted. W. W. Binkley

Evaporator control [for cane sugar mills]. G. W. Tompkin. *Repts. Hawaiian Sugar Tech.* **2**, 51-5(1939).—The necessary app. is described and illustrated. J. C. Jurrjens

Evaporator automatic control [for cane-sugar mills]. A. K. Kinney and J. Eldon. *Repts. Hawaiian Sugar Tech.* **2**, 56-7(1939).—Various structural, elec. and operative details are given including illustrations. J. C. Jurrjens

The methoxyl and uronic acid content of the sugar cane. C. A. Browne and Max Phillips. *Intern. Sugar J.* **41**, 430-2(1939).—Perceptible amts. of methoxyl and uronic acid compds. occur in the filtered sugar-cane juice and these percentages are considerably affected by different methods of treatment. Hot maceration increases both the methoxyl and uronic acid compds. Liming the filtered juice decreased the uronic acid compds. but did not affect the methoxyl. Liming the unfiltered juice increased both the constituents considerably, probably because the action of the lime on the finely divided cane fiber liberated these compds. D. P. Langlois

A report on the uses of the by-products of the cane-sugar factory. Carlos L. Locsin. *Sugar News* **20**, 467-70, 517-21(1939); **21**, 557-60(1940); cf. *C. A.* **33**, 7139[3].—Known and possible uses of cane-sugar factory by-products are: from bagasse, fuel, bagasse board, cellulose and dry-distn. products; from filter cake, fertilizer, wax and fuel; from molasses, compressed yeast, glycerol, dry ice, cattle feed, fertilizer, road material, plastics, ethanol, butanol, acetone, acetic, lactic, citric, butyric and gluconic acids; electrolytic caustic, Cl, bleach and H. W. W. Binkley

The keeping quality of cane-sugar molasses. H. C. Prinsen Geerligs. *Intern. Sugar J.* **42**, 25-7(1940).—See *C. A.* **33**, 7142[4]. D. P. Langlois

Harmful nonsugars and sugar beets. H. Claassen. *Centr. Zuckerind.* **47**, 1029(1939).—An increase of the harmful N content of sugar beets and juices reduces their purity and ease of workability. Harmful N is not the sole measure of quality, since the purity of defecated and carbonated juices must be considered also. References to suitable methods and app. are given. W. W. B.

New viewpoints on the purification of sugar-beet extract. Fritz Tödt. *Chem. App.* **26**, 370-2(1939).—A lecture. G. W. Stroebe

Behavior of topped beets remaining in the ground. H. Claassen. *Centr. Zuckerind.* **47**, 1013-14(1939); cf. *C. A.* **33**, 9034[1] and 2 following abstrs.—Sugar losses by the Pommritz process are no greater than in the usual harvesting methods. They contained only 0.02-0.03% more invert sugar than untopped beets. W. W. Binkley

Sugar content of and yield from Pommritz beets after they remained in the ground different lengths of time. K. Sammet and W. Lesch. *Centr. Zuckerind.* **47**, 1065-7 (1939); cf. preceding and following abstrs.—Pommritz process beets after 4 or 8 days in the ground showed a decrease in sugar content up to 1.5%. This decrease depends on exptl. conditions, H_2O absorption, the time the beets are left in the ground, and damage inflicted by topping. An increase in nonsugar content accompanies the decrease in sugar content. W. W. Binkley

Pommritz process in 1939. Fritz Schneider. *Centr. Zuckerind.* **47**, 1095-6(1939); cf. 2 preceding abstrs.—Pommritz process beets soon after topping show 0.8-1.6% less polarization. The beets lost 1.1% sugar after 4 days in the ground; 1.7% after 8 days. No deterioration in juice quality was detected. Sugar losses can be reduced by shortening the period between topping and plowing up of the beets. W. W. Binkley

Influence of beet chips on diffusion work. Bielitzer-Gronau. *Centr. Zuckerind.* **47**, 980-2, 1000-1(1939).—Most of the leaching occurs in the first 2 units of a battery with 7 diffusers and in the first 3 units in a battery of 8. The decrease in sugar concn. in the last 3 diffusers is the same for batteries of 7 or 8 units. Small chips do not distribute uniformly throughout the diffusers while even smaller chips cause foam. A combination of the smaller

chips and solns. of greater vol. does not shorten the diffusion time. Dead spaces between the diffusers has no favorable influence. W. W. Binkley

Solubility of sucrose. R. Hrubý and V. Kasjanov. *Intern Sugar J.* 42, 21–4(1940).—The nonsugars greatly affect the soly. of sucrose in water. The compn. of these nonsugars has been shown to differ considerably not only with products from different countries but also with sirups of the same factory and even with the same product throughout the campaign. Because of this it is useless to expect to calc. true values from apparent figures, e. g., purity coeffs., or the total salts from the sulfated ash. A simple and rapid method of detg. the soly. of cane sugar is not now available but is badly needed, since all existing data appear to be in considerable error. D. P. Langlois

Grut's experiments on the solubility of sucrose in the presence of nonsugars. Ph. Orth. *Bull. assoc. chim.* 56, 705–8(1939); cf. *C. A.* 8, 2632; 31, 7311⁴.- Grut's expts. (*C. A.* 32, 3185[6,7,8,9]) show that the soly. of sucrose is influenced by impurities in or on the crystals. The results accord with the equation $e = a(b - t)$, where e is the percentage ratio of H_2O to sugar in the satd. soln., t is the temp., and a and b are consts. For pure sucrose $a = 0.3901$, $b = 147.47$. As the purity of the sugar decreases, a increases, while b decreases. At 60 purity $a = 0.5062$, $b = 113.24$. At $e = 0$ the sugar concn. = ∞, and b indicates the m. p. of the sugar, falling with decreasing purity as would be expected. The product ab, indicating e at $t = 0$, is practically const., irrespective of purity. As the temp. decreases the effect of the purity on the soly. becomes less, and at 60 purity and $t = 0$ the satn. coeff. is only a little above unity. These relations have been confirmed by practical experience. F. W. Z.

Mannan. VIII. Preparation of mannan and the effect of temperature. Torao Otuki. *J. Chem. Soc. Japan* 60, 76–87(1939); cf. *C. A.* 31, 8610⁶.—Decrease in soly. of mannan is attributed to absorption of water; on preservation in a glass bottle for 5 yrs. it was unchanged. Decrease of soly. on heating, reported by various observers, was not confirmed. The viscosity of mannan soln. decreases on heating; the higher the temp. and the longer the time of heating, the greater is the decrease. This change is due to neither hydrolysis nor oxidation, but probably to a decrease of force necessary to build up colloidal micelles, such as the van der Waals force. Purification of mannan by (1) pptn. of cold aq. soln. with alc., (2) digestion of the colloidal soln. with pancreatin and pptn. with alc., and (3) pptn. of the Cu compd. of mannan by addn. of Fehling soln. and subsequent removal of Cu gives, resp., a prepn. most closely approximating the natural product, mannin-A, which differs from mannan only in that it is slightly less viscous, and a prepn. that swells in water but does not dissolve. Purified acetylated mannan was obtained from the dried powder. Mannan prepd. from this by deacetylation was insol. in water. K. Shinohara

Bagasse weighing. S. S. Peck. *Repts. Hawaiian Sugar Tech.* 2, 85–7(1939).—Several methods are given and described in detail in order to arrive at more accurate figures than the ones used at present. J. C. J.

Researches on the thermal conductivity of massecuite and application to the cooling in an Adant mold. E. A. Marie and P. B. Naeĉache. *Sucr. belge* 59, 161–70 (1940).—The quality of the grain has little influence on the thermal cond. of massecuite. Thermal cond. of refined massecuite (Brix 90–95°) is a function of the wt. of crystals in 1 kg. of massecuite. W. W. Binkley

New views on starch. Karl Freudenberg, Ernst Schaaf, Gertrud Dumpert and Theodor Ploetz. *Naturwissenschaften* 27, 850–3(1939).—Recently the structure of the cryst. dextrins (Schardinger) of which starch is built up was detd. (*C. A.* 32, 8373⁶); it was assumed (*C. A.* 33, 6806⁸) that these compds. are present as such in starch. A model was built of the ring-shaped α-dextrin (pentosan) with the glucose units perpendicular to the plane of the ring. No fewer than 5 glucose units are required to produce such a ring without tension. The ring of the pentosan has the 5 O atoms of the 1–4 bonds arranged in an equilateral pentagon; C atoms 1 and 4 lie in one plane and the other C atoms in a 2nd plane. In β-dextrin, with 6 units, the corner O atoms are in 2 planes. With these dextrin structures the Hanes screw model of starch (*C. A.* 31, 8611⁹) becomes most acceptable; the dextrin structures are preformed in this as single coils of different sizes. The model explains hydrolysis by α-amylase as well as formation of nonreducing dextrins by the amylase of *Bacillus macerans*. The screw-shaped starch mol. is 15–20 A. thick and the rods are arranged radially in the concentric layers of the starch grain. Several other details, including the effect of I, are discussed. B. J. C. van der H.

Sirup from sweet potato starch. Lawrence E. Stout. *Mfrs. Record* 109, No. 2, 33, 48(1940). - The hydrolysis of a slurry of the starch in water (about 25 Be.) with HCl at a pressure of 30–50 lbs. for 20 min. followed by neutralization, purification and concn. yields a clear faintly colored sirup (35–42 Be.) which in every respect is comparable with corn sirup. Leopold Scheiban

Correlation between soil type, manure requirement and compn. of juice in sugar cane (Brink, van den Honert) 15. Nutrient solns. for sugar beets in sand and water cultures (Ukradyga, Oleksyuk) 15. (Lime and) beet leaf ratio in sugar beets (Berkner) 15. App. for sepg. solid particles of different sizes in starch manuf. (U. S. pat 2,184,598) 1.

Purifying sugar-factory and refinery juices. Dario Teatini. U. S. 2,184,570, Dec. 26. Sec Brit. 501,754 (*C. A.* 33, 7711[1]).

Desiccating molasses. David D. Peebles, (to Golden State Co., Ltd.). U. S. 2,184,314, Dec. 26. App. is described, and a process which involves causing a continual flow of the molasses under pressure to a discharge orifice, heating the molasses during its flow to an elevated temp. to initiate degradation of its sugar content, causing the molasses discharging from the orifice to be atomized with simultaneous release of water vapor and gases incident to partial degradation of sugar, causing the atomized particles to come into contact with a heated drying gas, and then arresting further degradation of sugar by rapidly cooling the particles.

29—LEATHER AND GLUE

HENRY B. MERRILL

Acid-binding power of collagen. G. D. McLaughlin and R. S. Adams. *J. Am. Leather Chem. Assoc.* 35, 44–50(1940). Collagen was prepd. from unhaired and bated calf skin by deliming with small increments of HCl at pH = 5, and washing free from electrolytes. The product was cut into strips, dehydrated with acetone and air-dried. Samples were treated 24 hrs. with solns. contg. varying wts. of H_2SO_4. The acid-treated collagen was pressed at 5000 lb./sq. in. and air-dried. It was assumed that all the H_2SO_4 in the pressed collagen was combined. Analysis of the air-dried collagen showed that H_2SO_4 content increased as the logarithm of the total wt. of H_2SO_4 present in the system, up to 7 g. H_2SO_4 combined with 100 g. collagen when the total H_2SO_4

present was 19 g. per 100 g. collagen. For higher wts. of total H_2SO_4, the acid present in the pressed collagen was greater than the wt. predicted by the logarithmic relation. H. B. Merrill

Report of the committee on qualitative tannin analysis of the I. S. L. T. C. A. Jamet, *et al.* *J. Intern. Soc. Leather Trades Chem.* **23**, 576–83(1939); cf. *C. A.* **31**, 6918⁶.—The tests previously recommended were applied by different labs. to samples of quebracho, sulfited quebracho, chestnut, mimosa and myrobalans exts., either pure or admixed with other exts. Results show (1) hydrolyzable tannin (I) can always be detected in condensed tannin (II); (2) II can always be detected in I, but sometimes the presence of II is indicated falsely; (3) admixt. with chestnut of hydrolyzable tannins of a different subgroup generally can be detected; (4) admixt. of II with another example of II cannot be detected (e. g., 20% urunday in quebracho, and 10% mangrove in mimosa escaped detection by half the collaborators). H. B Merrill

Report of the [A. L. C. A.] committee on color values of tanning materials. J. C. Robinson. *J. Am. Leather Chem. Assoc.* **35**, 213–15(1940).—The solns. prepd. for detg. sol. solids were examd. by different labs. with either Blackadder's modification of the Schmidt and Haensch colorimeter or a photoelec cell colorimeter. With neither instrument have concordant results been obtained. The differences are blamed on variations in turbidity of the sol. solids soln. as prepd. in different labs. H. B. Merrill

A method for the analysis of sulfited extracts (sulfited quebracho). III The determination of (8) hydrogen sulfide and (9) true sulfonic acids of the nontans. H. G. Turley, I. C. Somerville and F. P. Cronin. *J. Am. Leather Chem. Assoc.* **35**, 208–13(1940); cf. *C. A.* **33**, 2754⁶. The 7 detns previously described accounted for nearly all the S of the quebracho exts. originally investigated, but when the methods were applied to other samples, particularly of British and French manuf., up to 20% of the S was not accounted for. The gas evolved in detg. hydroxysulfonic acids contains H_2S. This was detd. by absorption in 2 tubes contg. 2% $CdCl_2$, placed ahead of the tubes contg. H_2O_2, and detg. the absorbed H S iodometrically. It was found further that the nontannin filtrate, after pptg. sulfates, contained S that could be recovered as $BaSO_4$ after oxidation. As sulfites and hydroxysulfonic acids had been removed before sepg. the nontannin, it was concluded that the nontannin filtrate contained true sulfonic acids of nontannins. These were detd. by evapn. with fuming HNO_3 and pptn. as $BaSO_4$. When all the methods were applied to 10 sulfited quebracho exts. of diverse origins, contg. from 1.7 to 5.9% S as SO_3, the percentage recovery of the S varied from 96 to 103%. The wide variations between different exts. in distribution of S are shown by the following figures (as percentage of the total S) free SO_2, 0.0 to 5.0; bisulfite, 0.0 to 24.8; sulfite esters, 9.6 to 18.4; hydroxysulfonic acids, 21.0 to 58.3; true sulfonic acids (*a*) of tannins, 2.3 to 15.1; (*b*) of nontannins, 0.0 to 9.7, H_2S, 2.3 to 19.8; sulfate, 7.6 to 37.3. H. B. Merrill

Action of microörganisms on vegetable tanning materials. X. The effect of sodium bisulfite on lactic acid fermentation of various tanning materials. Paul C. Chang. *J. Am. Leather Chem. Assoc.* **35**, 193–205 (1940); cf. *C. A.* **33**, 4077⁶. Lactic acid formation was measured in tan liquors contg. variable wts. of $NaHSO_3$ by the methods previously employed. In ellagitannins (myrobalans, valonia, California oak) fermentation was inhibited by 0.5% $NaHSO_3$ at pH = 5, and by smaller amts. at lower pH values. With condensed tannins (hemlock, mangrove), the effect of 0.5% $NaHSO_3$ was about the same, but 0.1% had no effect, probably because it combined with the tannin. Calcn. showed that the SO_2 content of the sulfited quebracho commonly used in a com. blend probably inhibits fermentation in the head liquors, but not in the tail liquors. H. B. M.

Study of accelerated tannage. Fernand Pothier. *J. Intern. Soc. Leather Trades' Chem.* **24**, 34–48(1940).—P. means a tannage in which exts. are used along with decoctions of bark, instead of the bark decoction only. Tanning expts. were performed with pieces from the bend of a selected, unhaired, delimed cow hide. The process included (1) "coloring" (1 week) in oak bark liquor, 0.5° Baumé; (2) tannage in "rocker" liquors (4 weeks), with liquors made by strengthening the color liquor with an ext., initially to 1° Baumé and increasing by 1° each week; (3) "retanning" (4 weeks) in oak bark decoction (2.5° Baumé) plus added bark; (4) "layaway" (3 months) in ext. liquor (3° Baumé) plus added oak bark. The exts. used were: oak wood (I), chestnut (II) (3 samples, variously processed), sulfited quebracho (III), mimosa (IV), "Swedish" spruce (V), myrobalans (VI), valonia (VII), gambier (VIII). *Results:* Yield (ratio of dry leather wt. to dry hide wt.) was highest for I, slightly less for II, III, IV and VII, and much lower for V, VI and VIII. This agreed with degree of tannage detd. by analysis. Coeff. of turgidity (*C. A.* **30**, 320⁹) was highest for I, II, IV, V and VII, slightly lower for III and VI, and lowest for VIII. Permeability to H_2O was least for I (24 min. per mm.), moderate for II to VII (7 to 14 min. per mm.) and very high for VIII (1.5 min. per mm.). Absorption of melted tallow agreed with permeability to H_2O; absorption of oil from a water emulsion contg. moellon, fish oil and tallow followed a slightly different order. Microscopic examn. confirmed the findings as to solidity. It is concluded that I, II, VII and IV are best adapted to sole-leather manuf., in the order given; the other exts. are better adapted to the manuf. of upper and fancy leathers. The characteristics of the leather are detd. by the exts. used in the rockers, and are modified only slightly by subsequent retannage. H. B. M.

Aging and reversibility of basic chrome sulfate tannage. G. D. McLaughlin and R. S. Adams. *J. Am. Leather Chem. Assoc.* **35**, 130–2(1940).—The aging expts. previously described (*C. A.* **32**, 9547⁶) were extended to 1 yr.; the same technique was used. For leathers of 18% and 22% basicity, resp., the percentages of reversal decreased from 61 and 80 to 38 and 61 after 26 weeks, and to 35 and 59 after 52 weeks. H. B. Merrill

The influence of organic compounds in chrome tanning. I Quinone, quinhydrone, hydroquinone and sucrose. H. C. Holland. *J. Intern. Soc. Leather Trades Chem.* **23**, 571–5(1939).—In 0.01 *M* chrome alum soln., addn. of no one of the above compds. has any effect on pH value or ionic sulfate, as detd. by electrometric titration and by pptn. with benzidine. This indicates that none of these compds. displaces coördinately bound sulfate in such dil. soln. H. B. Merrill

The present status of tanning by means of polymeric anhydrous phosphates. K. Lindner. *Atti X° congr. intern. chim.* **4**, 877–89(1939).—A review with 11 references. A. H. Krappe

A proposed standard gas chamber for accelerated aging of leather. R. W. Frey and C. W. Beebe. *J. Am. Leather Chem. Assoc.* **35**, 180–92(1940); cf. *C. A.* **28**, 6339⁶.—SO_2 is supplied by burning MeOH contg. a fixed wt. of amyl sulfite in a const.-level lamp. Temp. is regulated electrically. Details of construction are given. Data are presented which show that SO_2 content of the chamber is very uniform over several months, and that percentage of deterioration of a leather is not affected by its position in the chamber. H. B. Merrill

A comparative examination of various methods for estimating buffer capacity and decay in leather. W. R. Atkin and S. G. Shuttleworth. *J. Intern. Soc. Leather Trades Chem.* **23**, 564–70(1939); cf. *C. A.* **33**, 9709⁸.—Buffer capacity (as percentage of H_2SO_4) was detd. for 3 leathers by: I, Shuttleworth's cond. titration method; II, the Atkin-Thompson method; III, the Procter-Searle method. I and II were in agreement when extn. in I was done with 0.04 *N* KCl as in II. III gave widely divergent results; e. g., in one leather III indicated 1.0% free H_2SO_4 while I and II indicated the presence of compds. capable of neutralizing 0.7% H_2SO_4. It is shown how the arbitrary crit. pH values of II can be found from the cond. curves of I. In further analyses of 11 leathers, sound and decayed,

the results obtained by **I, II, the Kohn-Crede method** (cf. *C. A.* **17**, 2201) and the Innes diln. method led generally to the same conclusions. I is considered most precise, rapid and convenient. Decayed leathers contain $(NH_4)_2SO_4$ which is returned as H_2SO_4 by **III**. When the $(NH_4)_2SO_4$ contents of the leathers were subtracted from the acid contents found by **III**, the corrected results were in much better agreement with the strong acid found by **I**.

H. B. Merrill

Comparative evaluation of the qualities of various white pigments for coating leather. S. P. Zel'din and E. A. Chumakova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 459–61(1939).—The tested white pigments can be arranged in the following decreasing order of their properties. Elasticity: white lead, ZnS, raw and calcined ZnO, lithopone and TiO_2. Covering power: ZnS, TiO_2, ZnO and white lead. Whiteness: ZnS, TiO_2, noncalcined ZnO, lithopone (29%), calcined ZnO and white lead.

Chas. Blanc

Products for use on leather. Friedrich von Artus. *Farben-Chem.* **10**, 164–70, 177–83, 203–8(1939); cf. *C. A.* **33**, 7145⁸.—This is a review of formulas and methods for making leather dressings, finishes, polishes, etc.

J. W. Perry

"Velan" treatment of light leathers. H. C. Holland. *J. Intern. Soc. Leather Trades' Chem.* **23**, 598–601(1939). —This finishing material is made by coupling pyridine and a higher alc. through HCHO. The hydrochloride, sol. in H_2O, is applied to fibers or fabrics. On brief heating at 100°, the compd. dissocs., and pyridine and HCHO are expelled; a waxy alc. coating is left on the fibers. This coating, being nonwetting, makes the fabric water-repellent without impairing its ventilating properties. Tests show that Velan treatment makes light leathers more water-repellent.

H. B. Merrill

The role of the chemical constituents of sulfated oils in the fat liquoring of chrome leather. Robert M. Koppenhoefer and Clinton E. Retzsch. *J. Am. Leather Chem. Assoc.* **35**, 78–129(1940); cf. *C. A.* **34**, 1970⁶. - The object of this work was (1) to compare 3 com. sulfated oils often used in leather making: neatsfoot (**I**), cod (**II**) and castor (**III**); (2) to study the effect of varying the constituents of each of these sulfated oils: sulfo compds. (**A**), free fatty acids (**B**), neutral oil (**C**) and raw oil (**D**) **A, B** and **C** were obtained by fractionating the sulfated oil by Hart's method (*C. A.* **31**, 4012⁹). Eleven series were run. In each series, one of the sulfated oils was mixed with one of the components of the same sulfated oil (or with the corresponding raw oil) to give 6 liquors of const. total oil content, varying from 100% sulfated oil to 100% added component by steps of 20%. E. g., in Series **IA** the different members of the series contained varying proportions of sulfated neatsfoot oil and the sulfo compds. isolated from sulfated neatsfoot oil. The leather was the bend portion of com. Cr-tanned calf skin, cut into strips after tanning, washed and neutralized with Na_2CO_3. Fat-liquoring conditions were: 300 g. wet Cr leather, 600 cc. liquor, 6 g. total oil, 48°, pH = 5 to 6, 1 hr. at 30 r. p. m. The fat-liquored leather was stored wet for about 16 hrs. at 15° and then air-dried. Representative strips were conditioned and exam'd. for (**a**) tear resistance and (**b**) tensile strength. The broken strips were analyzed either immediately or after aging 2 weeks. Free oil (**c**) was detd. by extg. successively with petr. ether and Me_2CO. Combined oil (**d**) was detd. by hydrolyzing the extd. leather with 20% KOH and extg. the lipides from the acidified hydrolyzate with Et_2O. Total oil (**e**) = **c** + **d**. Other strips were split into "grain" (upper 20%), "corium base" (lowest 20%) and "corium" (middle 60%), each of which was analyzed separately. Results are given in 33 graphs. Results showed: (1) in whole skin **e** was independent of the compn. of the fat liquor except in **IC, IIIB, IIIC** and **IIID**, where takeup was very incomplete for expts. with 100% **C** or **D**. **d** was directly proportional to **A**. **d** increased slightly on aging. There was no evidence that **B** contributed at all to **d**. (2) In the grain layer, **c, d** and **e** increased with **A** and decreased with **B, C** and **D**. This means that penetration through the grain surface is detd. by the fineness of the emulsion. In the corium base, in **IA, IIA** and **IIIA, e** was const, **d** increased and **c** decreased with increasing proportion of **A**. In **IB, IC, IIC, IIIC** and **IIID, d** decreased and **c** and **e** passed through max. with increasing proportion of **B, C** or **D**. In **IIB** and **IIIB, c** and **e** increased with increasing **B**, and in **IID c** and **e** passed through min. with increasing **D**. In the corium proper, the percentage of total oil was only about 1/10 that of the grain or corium base and **d** was always very small. In poor emulsions most of the oil penetrated through the open structure of the flesh side, and subsequent penetration of **c** into the corium proper occurred by flow of oil along the fiber surfaces. The amt. of **c** and **e** found in the corium was largely a function of the amt. found in the corium base. In general, penetration was better for **II** than for **I** and **III**. (3) **a** and **b** decreased with increasing percentage of **A** in **IA, IIA** and **IIIA**. The sulfo compds. are incapable of lubricating leather and serve merely as dispersing agents. Generally, but not always, the results of **a** and **b** were in accord. **b** depends largely on the **c** content of the corium proper. With increasing proportion of **B, C** or **D, a** and **b** usually passed through max., but in **IIB** and **IIC a** and **b** were max. at 100% **B** or **C**, because **B** and **C** from **II** have fair emulsifying properties. In **III B, a** decreased and **b** increased with increasing proportion of **B**. As between the different oils, **a** and **b** decreased in the order **I, II, III**. **I** gave outstandingly high values, and appears to be a superior lubricant regardless of distribution. The effectiveness of the different components declined in the order **D, C, B**. The differences were not great. **C** differs from **D** in containing a high proportion of mono- and diglycerides.

Some causes of variation in the quality of raw rubber and latex. The sol:gel ratio in relation to the ultimate physical properties of rubber. D. Spence and John D. Ferry. *J. Soc. Chem. Ind.* **58**, 345–51(1939).—A continuation of previous work (*C. A.* **31**, 8247[4]). Evidence is presented to show that changes from sol rubber (I) to gel rubber (II) (increase in the state of polymerization) and conversely from II to I (depolymerization) take place in the prepn. of raw rubber to an extent that makes the phenomena of practical importance. The percentage of II in NH_3-preserved latex increases progressively during storage, whereas that of sterile latex remains const. Rubber prepd. by coagulation with an acid contains a higher proportion of I than does rubber coagulated by natural exposure of the latex, and if an excess of acid is used, the percentage of I is still higher. Rubber prepd. from latex treated with a pure culture of Actinomycetes contains an abnormally high percentage of II, and it is harder and tougher than ordinary rubber. When latex is coagulated by smoking, the I:II ratio of the resulting rubber depends on whether the process is carried out in light or in darkness, i. e., smoked rubber prepd. in darkness contains a much higher percentage of I than does rubber prepd. in the same way except with exposure to sunlight during coagulation. Exposure of dry rubber to sunlight and to benzoquinone (III) vapor and also exposure in darkness to III and then to sunlight increase the II content, whereas exposure to III in darkness alone does not substantially increase it. Exposure of latex contg. 1,4-naphthoquinone (IV) to sunlight increases the II content, but if NaOH also is added, the II content decreases. Likewise the tendency of III and sunlight to increase the II content of neutral latex can be nullified by the addn. of sufficient NaOH or NH_4OH. The longer that latex contg. IV is exposed to sunlight the lower are the percentage of I and the swelling index, and the higher is the tensile strength of the rubber prepd. from the latex. Thus rubber prepd. from latex (34.5% rubber) contg. 1.2 g. of IV per 350 cc. and exposed for 10 hrs. was 5 times as strong as the corresponding rubber not so treated, and the elongation at rupture was the same. After vulcanization, products from latex treated in this way are stiffer and reach their optimum cure (judged by tensile strength) sooner than do products from normal latex. In general, these products differ in mech. properties in the same way as do the I and II vulcanizates described by Smith and Holt (*C. A.* **29**, 1679[3]). In Diesel oil the vulcanizates from the treated latex swell less than the corresponding ones from untreated latex. When latex contg. BzH (2.5% on the rubber) is exposed to sunlight: (1) in N; (2) in air; (3) in N and then in air; S and Zn butylxanthate are then added to each sample, and the samples are coagulated, the rubber from (1) is very tough and resilient before and after vulcanization; sample (2) is soft and plastic before, and short and weak after vulcanization, and sample (3) is much less plastic than (2) before vulcanization and short and tough after vulcanization. After vulcanization, the samples prepd. from rubber treated with BzH swell much less in Diesel oil than do the corresponding samples from untreated rubber. In general, changes in the I·II ratio of rubber by the combined action of sunlight and IV or BzH are manifest before vulcanization by diminished soly. and swelling and increased tensile strength. These differences are, however, masked to some extent after vulcanization by the mech. treatment undergone by the rubber. But the expts. show the changes in structure and improvements in phys. properties that are retained after vulcanization and, by the use of BzH and light, as a "bridge builder" in the absence of air and as a "chain breaker" in the presence of air, products with various degrees of soly. and swelling properties can be obtained. A method is thus made available for the prepn. of modified rubbers, as suggested by Rideal (*C. A.* **32**, 8195[8]), whereby the phys. structure of natural rubber may be so changed that vulcanizates can be obtained which are more nearly like the best synthetic rubbers in their resistance to various org. liquids to which ordinary rubber is

so much less resistant. The dependence of the I:II ratio in com. rubber on methods of storage and coagulation of the latex, on bacterial action, on the action of light and heat during the smoking process, on the presence of alkalies, etc., and in turn the influence of this I:II ratio on the properties of the vulcanized rubber throws further light on the variability of com. rubbers. Structure and mechanical properties of rubber. K. H. Meyer. *Atti X° congr. intern. chim.* **4**, 100–1(1939).—Owing to the fact that a rubber-like substance is built up from very long primary-valence chains, it exhibits microscopically the behavior of a liquid in 2 directions (viscosity smaller than 10^8 c. g. s. units) and that of a solid in the direction of extension (viscosity larger than 10^{12} c. g. s. units). The kinetic theory of the elasticity of rubber is discussed. The viscosity of rubber increases considerably with increasing deformation. R. Simha

Lattice of rubber. Lore C. Misch and A. J. A. van der Wyk. *J. Chem. Phys.* **8**, 127(1940).—The unit cell of rubber suggested by several authors gives an x-ray d 8–10% higher than the measured d. The equator reflection A_2 is not a single reflection, and the angle between A_1 and A_2 is 39.2°. The rubber lattice is pseudorhombic with a = 8.97 A., b = 8.20 A., c = 25.2 A. The same cell in monoclinic parameters gives a = 8.97 A., b = 8.20 A., c = 26.7 A., β = 70.4°. The cell contains 16 isoprene units (8 chains); the calcd. d. is 0.97 (0.965 is the highest measured d. of stretched rubber). Certain difficulties connected with this interpretation are discussed. A smaller unit cell can exist only if several structures are present simultaneously (dimorphism). One must be monoclinic, the other may be triclinic. The monoclinic cell: a = 8.97 A., b = 8.20 A., c = 6.68 A., β = 70.4°, contains 2 chains. The triclinic cell: a = 6.12 A., b = 8.20 A., c = 6.99 A., α = 73.2°, β = 64.1°, γ = 47.1°, contains 1 chain. The softening of rubber. I. The addition of soaps and softeners to latex. V. H. Wentworth. *J. Rubber Research Inst. Malaya* **9**, Commun. 236, 90–100(1939).—The work was prompted by a realization of the potential advantages of softening rubber during its prepn. on the plantations, thereby avoiding the combination of heat, mastication and addn. of softening agents, with the resultant expenditure of power, now current in the rubber industry. Both older softening agents and new peptizing agents were tested as possibilities to add to latex and to soften rubber during smoking or drying. Fatty acids and soaps were added to latex, either as solns. or as C_6H_6-dil. NH_4OH emulsions. Stearic acid and its NH_4, Na, K, Mg, Ca, Zn, Al and Pb salts; oleic acid and its NH_4, Na, K, Cu, Mg, Ca, Zn, Ba, Al, Sn, Pb, Fe and Ni salts; palmitic acid and its Na, K and Al salts, and linoleic acid and its NH_4 and trihydroxytriethylamine salts were tested, and in each case 3% (on the dry rubber) was added. The effects on plasticity before and after mastication are tabulated. The free acids did not have any pronounced softening effects, but the soaps were more effective. Na soaps were slightly the best of the sol. ones, but were relatively ineffective. Cu oleate had an extreme effect, but obviously is still of no practical interest. Ni oleate had the greatest initial effect, followed by Zn oleate and Zn stearate and Fe oleate; however, the effects of the 3 were nearly the same after mastication. Sn oleate showed a hardening effect. Because of their proved safety in rubber, and their pronounced softening effects, particularly after mastication of the rubber, Zn stearate and Zn oleate were the most promising softening agents. Pine tar had relatively little softening effect, even in high proportions (up to 10%, based on the rubber, was added in the form of aq. emulsions to the latex). Rubber contg. low percentages of pine tar (added as an emulsion to the latex) and air-dried had the appearance of smoked sheet, and since large proportions of pine tar can be incorporated in latex, it might be economical for rubber-pine tar master batches to be prepd. on the plantations and the more cumbersome and costly process of prepg. such master batches in the rubber industry thus be avoided. Comparative tests of the softening action on rubber of pine tar, Tackol, Rubberine Gel, rosin oil, stearic acid, lanolin, petrolatum and coal tar, when added to latex, showed no outstanding effects. All gave practically the same plasticities after mastication. **II. The preparation of soft rubber by precoagulation treatment of latex.** J. D. Hastings. *Ibid.* Commun. 237, 101–25.—Four peptizing agents, viz., $PhHNNH_2.ZnCl_2$ (I), naphthyl-β-mercaptan (II) and xylylmercaptan (III), were incorporated, as emulsions, in latex and their ability to soften the resulting rubber while hot during the smoking and drying operations was detd. The peptizing agents had no significant effect on the coagulation, sheeting and smoking processes. Softness of the rubber was judged by plasticity and mastication values, obtained by the Mooney shearing disk plastometer. Because of the poisonous properties of I, the details of the exptl. results are not reported. II

had a pronounced softening effect, and the higher percentage, the greater was this effect. However, with 0.076% of II, the rubber was less plastic than without any II, but only before mastication. This apparent hardening is also manifest in the first stages of masticating ordinary crude rubber (cf. Hockstra, *C. A.* **32**, 8200[7]), although the explanation of H. seems invalid for rubber contg. II. When added to latex, II slightly accelerated the vulcanization of rubber-S mixts., but not of rubber-S mixts. accelerated by mercaptobenzothiazole-ZnO (Crude Rubber Comm. Am. Chem. Soc., recipe). There were no significant effects of II on aging, at least in the proportions likely to be used in practice. When II is added to latex, the plasticity of the resulting rubber depends on the temp. on drying of the wet sheets, e. g., a much softer rubber was obtained at 140° than at 120°. Moreover, the higher the percentage of II, the greater was this temp. coeff. Continued heating after rubber was dry did not increase its softness, and the temp. effect on softness was greatest in the early stages of drying. Hence high temps. are necessary only during the early stages of drying, and max softness is obtained by maintaining wet sheet at a high temp. in the early stages of drying and completing the drying at a lower temp. Greater softness of rubber contg. II (added to latex) and also normal rubber was obtained by milling it at 20° than at 80°. When stored, rubber contg. I, II and III, resp., hardened progressively, and the higher the percentage of peptizing agent, the greater was the hardening, and more hardening occurred in rubber dried at 140° than in that dried at 120°. Differences in plasticity of rubbers caused by inherent differences in latex were still evident when II was added to the latexes. The effects of III were in general similar to those of II, but III was not so effective as II in the same percentage. Emulsions of peptizing agents can be readily prepd. with a homogenizer, but this is not always feasible on plantations. However, the so-called "two-soln." method of agriculture can be utilized to prep. stable emulsions of II without a homogenizer. The best emulsions obtained were prepd. by adding a soln. of II and Agral WBS (Imperial Chem. Industries) in kerosene to an equal vol. of water contg. a little NaOH, e. g., 10 g. of II and 1 g. of Agral WBS in 100 cc. of water are added to 100 cc. of water contg. 0.5 g. of NaOH. This is added to latex dild. to 1.5 lb. dry rubber per gal. (0.72% II based on the rubber). II can also be handled in the same way. From the factory point of view this type of modified rubber is much more easily "broken down," and its economy warrants further study. C. C. Davis

The effect of silent electric discharges on rubber solutions. Lothar Hock and Heinrich Leber. *Kolloid-Z.* **90**, 65–77(1940).—Solns. of several concns. (mostly in C_6H_6) of natural rubber (I) and of Buna-85 (II) were subjected to a silent elec. discharge in an app. which was a modified form of that of Fromandi (*C. A.* **23**, 1009). This app. and the technique of the expts. are described and illustrated in detail. Under these conditions, both I and II undergo polymerization, with formation of products of various degrees of higher polymerization, some of which are sol., others insol. in benzene. The polymers insol. in benzene form, after purification and drying, a nonelastic, nonplastic mass which is soft and weak enough to be readily crumbled to a flaky material. On the contrary, the benzene-sol. products retain all of the plasticity and elasticity of the original rubbers, and from a technical point of view behave essentially like ordinary raw rubber. Some of the products were vulcanized, and it is particularly worthy of note that the properties of vulcanizates from the higher polymers of II are more nearly like the properties of vulcanizates from untreated natural rubber than they are like the properties of vulcanizates from the original II. Only by tests with various percentages of S, various accelerators and fillers, and other conventional methods of compounding, can it be ascertained whether these more highly polymerized products from I and II are of technical importance, either for general use or for special purposes. A significant fact in this connection is that these more highly polymerized products from I and II have considerably higher softening temps., without any loss of plasticity, tackiness and soly.; so perhaps even the products prepd. in the present work may be of technical importance. From the theoretical point of view, the formation of higher-mol. types of rubber is characterized by polymerization by forced activation of the mols. The progress of this polymerization is therefore governed by the elec. conditions, and this in turn explains why polymerization progresses in practically the same way through the temp. range of −25° to 50°. Analyses of the various polymerized products showed that all those from I had the empirical formula of isoprene, and all those from II had the empirical formula of butadiene. Both in chem. and physicochem. respects, the more highly polymerized forms of I and II are characterized by their degrees of unsatn. and accordingly by their I nos., which decrease with increase in mol. wt., i. e., with degree of polymerization. Furthermore thermochem. measurements, including detns. of the heats of combustion in a microcalorimeter, proved that the polymerization brought about by a silent elec. discharge is an exothermic reaction, for the higher the degree of polymerization the smaller is the heat of combustion of the polymerizate. It was found possible to follow, by measurements of the internal friction, i. e., changes in viscosity, the progress of polymerization to the point where a gel separates. C. C. D.

Ultraviolet irradiation of rubber. P. S. Srinivasan. *Proc. Indian Acad. Sci.* **10A**, 186–96(1939).—The effect of ultraviolet light on the absorptive capacities for light of rubber in polar and in nonpolar solvents was studied. Rubber highly purified from pale crepe was dissolved in the absence of air in menthol, ethylene chloride, cyclohexane and heptane and the solns., all of the same concn. (5 g. per l.), were exposed in the absence of air to radiation from a quartz-Hg lamp for 3 and 6 hrs. The absorptions before and after such treatment were measured with a Hilger Spekker photometer, a quartz spectrograph, isozenith plates and a condensed spark discharge between W-steel electrodes from a high-tension induction as the source of illumination. Compensation was made for absorption by the pure solvents, and the temp. was maintained const. The measurements, recorded in tables and graphs, confirm earlier observations that absorption of light by rubber is very small in the visible region, is greater below 2700 A., reaches a max. at approx. 2000 A. and is general rather than selective throughout. The most important result of the expts. is that irradiation with ultraviolet light increases the absorption of light by rubber in polar solvents and reduces it in nonpolar solvents, i. e., rubber becomes more nearly transparent in polar solvents and less transparent in nonpolar solvents. A review of work by

Staudinger, Pummerer, etc., leads to the conclusion that rubber in soln. is composed of true mols. and not micelles. If this is so, then polar solvents disrupt the mols., perhaps at points where the bonds are angular rather than linear. In nonpolar solvents, rubber is probably in a highly polymerized state; in polar solvents the degree of polymerization is much lower. Since ultraviolet light causes both polymerization and depolymerization (cf. Asano, *C. A.* **19**, 3616), a low degree of polymerization as in polar solvents should be increased by ultraviolet radiation and a high degree as in nonpolar solvents should be decreased. Furthermore before irradiation, light absorption by rubber is greater in nonpolar solvents than in polar solvents, and this indicates that the higher the degree of polymerization of rubber the greater is its absorption of light. Therefore ultraviolet light must increase the degree of polymerization in polar solvents and reduce it in nonpolar solvents. To confirm these views, the effects of ultraviolet radiation on the viscosities and surface tensions of solns. of rubber in heptane, cyclohexane, ethylene chloride and cyclohexanone were detd. Here too the operations were carried out in the absence of air, and irradiation was continued for 1 week. Prolonged irradiation reduced the viscosity in nonpolar solvents, originally 100 times that of the solvent, almost to that of the solvent. In contrast to this, the viscosity in polar solvents, originally 4–5 times that of the solvents, decreased only about 25%. Irradiation changed the surface tension inappreciably. These facts indicate that ultraviolet radiation breaks down the rubber mol. in nonpolar solvents, but relatively little in polar solvents, as would be expected if the mols. are already broken down and relatively small in polar solvents. This does not, however, prove whether polymerization takes place in polar solvents by irradiation with ultraviolet light. Further evidence on the mol. dimensions under various conditions might be obtained by a study of the depolarization of scattered light by the method used by Krishnan (*C. A.* **29**, 1301[7]) for colloids and mixts. of liquids. C. C. Davis

Aging of rubber-sole materials. I. U. Mishustin. *Kozhevenno-Obuvnaya Prom. S. S. S. R.* **1939**, No. 7, 33–6.—The effects of various commonly used ingredients are shown. B. Z. Kamich

Methods for determining the colloidal-chemical characteristics of sodium-bivinyl rubber. I. I. Zhukov and V. A. Komarov. *Sbornik Trudov Opytnogo Zavoda im. S. V. Lebedeva* **1938**, 3–11; *Khim. Referat. Zhur.* **2**, No. 5, 19(1939); cf. *C. A.* **33**, 4109[1].—The colloidal-chem. properties of Na-bivinyl rubber were detd. from the soly. of the rubber, from its fractional compn. and from the η of its dil. solns. A detailed description of the methods of these detns. is given. Measurements of the η were performed in an Ostwald viscometer for volatile substances (the vol. of the upper ball was 1 cc. and the diam. of the capillary 0.2 mm.). 0.25% solns. of the polymers in C_6H_6 were used for the detns. The soly. detns. were made by shaking the samples of the polymers in little batiste bags in C_6H_6 and by detg. the soly. of the polymer from the concn. of the soln. The soly. of the coreless rubber increased from milling (after 45 min.'s milling the rubber dissolved in 24 hrs.). The rate of soln. was increased 10-fold by heating the rubber on a water bath. The ratio solvent sample, can vary between wide limits without important changes in the soly. The soly. of rubber decreased when the rubber was kept in storage. The sepn. of the polymers was performed by fractional pptn. with alc. from C_6H_6 solns. of the polymers. To 3 portions of 25 cc. of 1% soln. of the polymer add 7.6, 17.4 and 34.7 cc. of alc., resp., let stand overnight and det. the wt. of the ppt. by drying to const. wt. at 75–85°. These amts. of alc. correspond in general to the pptn. of the 1st and the 2nd fractions. The 3rd fraction is pptd. by an excess of alc. and the 4th fraction remains in soln. and is detd. from the difference. W. R. Henn

New transformation products of rubber. H. Mark and K. Posnansky. *Atti X° congr. intern. chim.* **4**, 98–9(1939).—An acetone-water soln. of $AgNO_3$ was applied to films of latex. According to the duration of treatment, enclosures up to 18% of Ag, corresponding to about 37% of nitrate, were obtained. The final product was a solid, dry film with leather-like properties and a d. of 1.25 (18% Ag; d. of the initial product 0.923). The x-ray diagram showed a series of sharp rings. These rings, however, can neither be attributed to a Ag compd. nor can they be compared with those obtained from ordinary cryst. rubber. Also, the diagram obtained from a stretched sample differed from the corresponding normal sample. After being treated, the sample had a tensile strength of about 15–20 times that of the original film. At room temp., the extension was to a greater part irreversible. It was impossible to obtain an analogous product by applying other metallic salts such as $AuCl_3$, $AgClO_4$ or $NaNO_3$. The min. amt. of enclosed $AgNO_3$ necessary to obtain the above effects could not be detd. Robert Simha

Modern antiseptics for the rubber industry. Robert A. Engel. *Rubber Age* (N. Y.) **46**, 163–4, 171(1939).—A review and discussion. Attention is called to 2 compds., both derivs. of Ph_3CH_2, which are particularly effective against *Staphylococcus aureus* and which are therefore recommended as suitable for use in rubber products. C. C. Davis

Effect of the physical and chemical properties of carbon black on its electrical resistivity. G. L. Roberts and E. G. Emmert. *Rubber Age* (N. Y.) **46**, 159–62(1939).—An *app.* is described and illustrated for measuring the elec. resistivity of C blacks. In this app., the C black is subjected to controlled pressure during the measurements, a condition found to be necessary to obtain comparable results. Five channel C blacks of differing particle sizes and percentages of moisture and occluded gases were tested. Before removal of moisture and occluded gases, the resistivities differed considerably, but no simple relations between particle size, moisture content and occluded gases on the one hand and resistivity on the other hand were established. Nevertheless, in general the smaller the particle size of a C black, the greater was its resistivity. After removal of moisture and occluded gases, the resistivities were lower in all cases. Furthermore, as a result of progressive flocculation or agglomeration, the coloring powers were reduced by the heat treatment. C. C. D.

Effect of particle size on processing properties and abrasion resistance of carbon black in tread stocks. G. L. Roberts. *India Rubber World* **101**, No. 5, 39–42, 48(1940); cf. *C. A.* **33**, 9714[1].—Four grades of channel C black, ranging from one with relatively large particle size to one with the smallest particle size used for tire treads, were tested in rubber alone and in a tire-tread recipe to det. the relations between particle size on the one hand and ease of processing and resistance to abrasion, resp., on the other hand. The processing effects were judged by 2 types (Dillon and Housatonic) of plastometer, the effects on quality after vulcanization by resistance to abrasion (Grasselli-du Pont machine) before and after artificial aging. Under these conditions the effect of C black on the ease of processing of the rubber or rubber mixt. contg. it and the effect of the black on the quality of the vulcanizate are functions of particle size, *i. e.*, the larger the particle size, the more plastic were the rubber and rubber mixt. contg. the black, and the lower was the resistance to abrasion of the vulcanizate. Conversely C blacks of relatively small particle size make rubber difficult to process but impart relatively high resistance to abrasion. These relations remained unchanged after aging. C. C. Davis

Practical evaluation of commercial rubber carbon blacks by x-ray diffraction. Geo. L. Clark and Herbert D. Rhodes. *Ind. Eng. Chem., Anal. Ed.* **12**, 66–71(1940).—The particle sizes and shapes of 18 com. C blacks were evaluated with the greatest possible precision, from the

widths of the diffraction interferences at points of half-max. intensity. Cylindrical samples were used for calcns. by the von Laue equation, and wedge-shaped samples for calcns. by the Scherrer equation. Very satisfactory checks were obtained by both methods. Most of the samples were found to be essentially equiaxed in the dimension of the altitude of a hexagonal right prism and the base dimension between 2 diametrically opposed apices. The x-ray results indicate far smaller dimensions than evaluated by microscopic observation, indicating aggregate formation. The method is extended to C blacks in rubber mixes and also those extd. from rubber mixes, with satisfactory agreement. The x-ray results are correlated with apparent d., particle area, surface, active surface from methylene blue adsorption and diphenylguanidine adsorption for the C blacks themselves; and tensile strength, 4% modulus, and Shore durometer data for C blacks in conventional tire-tread compds. G. L. C.

Polymers. I. Highly elastic deformation of polymers. A. P. Aleksandrov and Yu. S. Lazurkin. *J. Tech. Phys.* (U. S. S. R.) **9**, 1249-60(1939).—The deformation of a rubber-like substance consists of an ordinary deformation which is independent of time and a "highly elastic deformation" D having a relaxation time t. If the specimen is subject to a periodic force, then $D = D_0/(1-i\omega t)$ where i is $\sqrt{-1}$, and ω the frequency. In agreement with this equation, the D-temp. curves are shifted to higher temps. when ω increases; the max. value of D_0 is almost reached at a temp. which is the higher the greater is ω. The time t rapidly diminishes with rising temp., e. g., for polymerized chloroprene, from 10 sec. at $-40°$ to 0.1 sec. at $-25°$. ω varied from 1 to 1000 min.$^{-1}$. D-temp. curves are also given for vulcanized rubber, half-vulcanized ebonite, and methyl-*m*-acrylate resin; the curves for the latter are shifted by plasticizers to lower temps. For each of these substances there is an interval of temps. (about 20 or 40° wide) in which they are hard at high, and rubber-like at low, values of ω. **II. Dynamic method of studying elastic materials.** Yu. S. Lazurkin. *Ibid.* 1261 6.—Cylinders about 1 cm. wide and 0.4 cm. high were periodically compressed 1 2000 times per min. The max. deformation was 0.015 cm. The temp. was varied between -180 and 200°. Results for *rubber* + 3% S are given. The sharp increase of the deformation with rising temp. took place at a temp. which increased with frequency ω. The temp. at which the deformation was 0.5 of the max. deformation was $-55°$ for static forces and $-25°$ for ω = 1000 min.$^{-1}$; it increased by 5-9° for a 10-fold increase of ω. **III. Technique of mechanical tests of vulcanizates of rubber and plastics.** G. Gurevich and P. Kobeko. *Ibid.* 1267-79; cf. *C. A.* **32**, 1995[6]. The correct way of detg. the mech. properties of rubber, etc., is to measure the rate of increase of deformation at a const. force and various temps. Detn. of the deformation produced in, say, 5 sec. at various temps. may also be sufficient. The torsion of butadiene rubber plotted against temp. gives S-shaped curves. In the course of vulcanization these curves become lower and are shifted to higher temps.; when continued heating with S ceases to affect the curves, the vulcanization is complete. Torsion at room temp. alone is not a sufficient test for the degree of vulcanization. Ebonite is not plastic; the residual deformation observed by Church and Daynes (*C. A.* **30**, 6607) is a part of the highly elastic deformation, depends on the condition of the expt., and is explained by the effect of temp. on the rate of deformation. Polystyrene has also almost no plasticity; polystyrene samples deformed at a high temp. conserve their form, since the rate of deformation at room temp. is negligible, but they regain their initial shape on a 2nd heating. Ordinary heat resistance and brittleness tests of polymers are unreliable. J. J. Bikerman

The properties of polymers in solution. X. Ultrafiltrations of rubber solutions. Kurt H. Meyer and Jean Jeannerat. *Rubber Chem. Tech.* **12**, 774-7(1939).—See *C. A.* **33**, 3233[9]. C. C. Davis

Catalytic dehydrogenation of monoölefins to diolefins. Source materials for synthetic rubber and resins. Aristid V. Grosse, Jacque C. Morrell and Julian M. Mavity. *Ind. Eng. Chem.* **32**, 309-11(1940).—The following hydrocarbons were catalytically dehydrogenated to give conjugated diolefins of the same C framework: *n*-butenes, 3-Me-1-butene, 2-Me-1-butene + 2-Me-2-butene, 2-pentene, and cyclopentane. The reaction was carried out over alumina impregnated with 4% Cr_2O_3, at 190 mm. and at 600° with 0.34 to 0.75 sec. contact time. With cyclopentane, the temp. was 500° and contact time 1.85 sec. The diolefins formed were 1,3-butadiene from *n*-butenes, isoprene from the branched-chain pentenes and piperylene from 2-pentene. The once-through yields varied from 11 to 30%, and the ultimate yields of 1,3-butadiene up to 79%. Cyclopentane yielded about 9% cyclopentadiene. The diolefins were identified by the prepn. of cryst. derivs., either the maleic anhydride addn. compds., the tetrabromides or both. C formation in the dehydrogenation of olefins is considerably higher than in paraffins, and represents over 10% of the charge in some cases. Other expts. proved that C formation is favored by keeping the reaction products too long in contact with the catalyst and, conversely, can be minimized by short contact times. Edward J. Mahler

Gutta-percha and balata. IV. Its part in life, sport and industry. H. J. Stern. *Rubber Age* (London) **20**, 339-40 (1940); cf. *C. A.* **34**, 1513[9].—A general discourse on the properties of gutta-percha and balata which make them applicable to various products. C. C. Davis

Hard-rubber reactions. VI. Liberation of so-called free sulfur and changes in the acetone extract of vulcanized rubber by repeated extraction and heating. Seiiti Numaziri. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 319-21 (1939); cf. *C. A.* **32**, 2779[2].—Mixts. of rubber 100, diphenylguanidine 2, stearic acid 1, ZnO 10 and S 5, 25, 100 and 150, resp., were vulcanized for 60, 180 and 300 min. at 141°; the vulcanizates were extd. by acetone for 20 hrs. in N; the residues were heated in N at 141° for 2 hrs., and the extn. and heating were repeated 10 times. The acetone exts. and free-S values are plotted as functions of the times of extn. and heating. In general the free-S values descended to min. values, increased to higher values and again descended to values lower than the original values. This trend is ascribed to depolymerization which occurs during certain stages of vulcanization and which becomes active again after the accelerator is removed by the acetone extn. The location of the maxima depended therefore on the original degree of vulcanization. The course of the acetone-ext. curves was in general similar to that of the free-S curves, but, the probable formation of acetone-sol. substances by the repeated heat-treatment made this similarity less well defined in some respects. The mixt. contg. 50 parts of S was also extd. repeatedly without intermediate heatings. The trends of the free S and acetone ext. curves were similar to the corresponding curves for extn. and heating cycles, although the percentages of generated or liberated S of the samples which were extd. and heated were greater than those of the samples only extd. The results indicate that the idea that free S is always present in vulcanized rubber and can be completely extd. by acetone may be based on the false premise of ignoring the depolymerization which takes place during hot acetone extn.

VII. **True free sulfur from pure rubber-sulfur compound and changes in the acetone extract during repeated extraction and heating.** *Ibid.* 369–70.—A mixt. of deproteinized, deresinated rubber 100, S 50, was vulcanized for 120 and 300 min. at 141°; the vulcanizates were alternately extd. by acetone and heated, as in the previous expts. (cf. preceding abstr.), and the true free-S values were detd. by a modified form of the method of Kelly (*C. A.* **14**, 3167). The corrected acetone exts. were calcd. by the differences between total ext. and acetone-sol. S and S compds. After a given no. of cycles of extn. and heating, the percentage of true free S was less in the vulcanizate cured for 120 min. than in that cured for 300 min. With continued extn. and heating, the true free S decreased to a very low min., then increased. In the 300-min. vulcanizate, it returned to its original value. These facts indicate that continued extn. of free S cannot be explained by incomplete previous extn., but probably is attributable to depolymerization of the vulcanizates or some analogous phenomenon. Although purified rubber was used, the corrected acetone exts. representing the formation of resins from depolymerized or otherwise deteriorated hard rubber were relatively high at the beginning of the extn. and heating process. The changes in acetone ext. with continued extns. and heating were roughly the same as those in the true free S values, but with less sharp minima in the former case. C. C. Davis

Ebonite as an acid- and alkali-resisting material in industry. H. van der Meijden. *Rubber* (Amsterdam) **2**, No. 6, 5–7(1939).—The construction of tanks for holding acids, alkalies, latex, etc., is described. N. B.

Rayon for tires. L. A. Yerkes, Jr. *India Rubber World* **101**, No. 3, 41–5, 49(1939).—An illustrated description of present developments. Cordura rayon has been developed especially for tire cords and is much stronger than standard rayon, i. e., 3.2 and 1.8 g., resp., per denier dry capacity. Also the stress-strain curves are different, e. g., Cordura yarn shows no point at which it commences to elongate rapidly with increase in load. The chief advantages of Cordura rayon over cotton are continuous filaments, uniformity, high strength when hot, very high resistance to fatigue, high tensile strength and price stability. C. C. Davis

Rubber as a construction material. Application in the water-works industry. D. J. van Wijk, Jr. *Rubber* (Amsterdam) **2**, No. 6, 8–10(1939).—The use of rubber for mains, conduit pipes, taps, etc., is described. N. Bekkedahl

Vulcanization of rubber. Harry L. Fisher. *Ind. Eng. Chem.* **31**, 1381–9(1939).—The chemistry of vulcanization and the various classes of vulcanizing agents are reviewed and discussed, and some hitherto unrecorded vulcanizing agents contg. no S and their effects in rubber under various conditions are described. Rubber is vulcanized by [ClN:C(NH$_2$)N:]$_2$ and by yellow HgO, and is changed to products approaching vulcanizates by PbO_2, SeO_2, $K_3Fe(CN)_6$, $HgCl_2$, $FeCl_3$ and pentammino carbonatocobaltic nitrate. On the basis of investigations by F. and others, several important generalizations about non-S vulcanization can be made: (1) most agents are in a broad sense oxidizing agents; (2) nonoxidizing agents are active only with oxidizing agents; (3) all agents combine in some unknown form with rubber hydrocarbon; (4) the unsatn. of rubber hydrocarbon decreases with increase in the quantity which combines with the agent; (5) all groups which combine with rubber hydrocarbon apparently are, or contain, polar groups; (6) a vulcanizing agent need not contain either S or O; and (7) the fundamental phenomenon common to vulcanization by every agent is oxidation-reduction. If the vulcanizing agent is in the reduced state, vulcanization does not take place unless an oxidizing agent is present, and in almost every case an oxidizing agent improves the quality with non-S reagents. The reduced compd. probably unites with rubber hydrocarbon and the addn. compd. is oxidized to a vulcanizate. By analogy a new *H_2S theory of the mechanism of vulcanization* is advanced. H_2S, formed by the action of S on the nonrubber components or on rubber hydrocarbon, adds to a double bond of the latter, with formation of rubber mercaptan. The latter is then oxidized by S to a disulfide, and H_2S is regenerated as a by-product. If the oxidized mercaptan groups are in the same mols., the disulfide structure unites 2 parts of the same mol.; if in different mols., the disulfide structure forms a bridge connecting 2 mols. Regenerated H_2S may react with another double bond and thus continue the reaction. S may catalyze the addn. of H_2S to a double bond. The reaction may be a chain reaction in which case only relatively little H_2S finally remains. An org. accelerator acts in 2 ways: (1) to catalyze the addn. of H_2S to a double bond and possibly catalyze the oxidizing action of S, and (2) in many cases to give H_2S by reacting with S. An inorg. accelerator acts directly as its corresponding sulfide; however, it does not furnish H_2S. The theory postulates that there should be a loss of 1 double bond per at. equiv. of combined S. This is in accord with known facts. Also the theory indicates that phenols and thiophenols in the presence of oxidizing agents vulcanize rubber, and this was confirmed by expts. Since H_2O is analogous to H_2S, it seemed possible that H_2O and an oxidizing agent would vulcanize rubber. This could not, however, be accomplished in several expts. Also in *Rubber Chem. Tech.* **13**, 50(1940). C. C. Davis

Preserving rubber. Louis H. Howland (to United States Rubber Products, Inc.). U. S. 2,183,567, Dec. 19. A process of preserving rubber comprises incorporating therein an age-resister comprising a preponderant proportion of the product of reaction of an aliphatic ketone with an arylamine and in addn. thereto an activating amt. of an aromatic diamino compd. selected from the class consisting of *N,N'*-diaryl-*p*-phenylenediamines and quinonoid diimine oxidation products thereof, and *N*-aryl-*N'*-acidyl-*p*-phenylenediamines. The preponderant treating agent may be a reaction product of acetone and diphenylamine.

Preserving rubber. Wm. Baird and Maldwyn Jones (to Imperial Chemical Industries Ltd.). U. S. 2,184,512, Dec. 26. To preserve rubber from oxidation, there is incorporated with it about 1% of 4,4'-dialkoxy-*N*-alkyldiarylamine in which the aryl groups are of the benzene series and each alkyl radical contains from 1 to 6 C atoms. Cf. *C. A.* **34**, 2208[1].

CHEMICAL ABSTRACTS

Vol. 34 MAY 10, 1940 No. 9

1—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

Work carried out at the National Physical Laboratory. Ezer Griffiths, J. H. Awbery and R. W. Powell. *Dept. Sci. Ind. Research* (Brit.), Rept. Food Invest. Board, 265–74(1939).—The rate of evapn. from surfaces of 17 and 31 cm. length can be increased by about 55 and 60% by the use of ridges, resp., 1 5 and 2.5 cm. in height. Latent heat values in g.-cal. per g. by direct measurement were found to be 7.8 for dichlorodifluoromethane, 17.0 for EtCl and 31.0 for MeCl. The thermal conductivities for these refrigerants were measured over a temp. range of 5 to 25°
J. S. Hicks

New laboratory devices. G. Kapsenberg. *Fette u. Seifen* **46**, 352–5(1939).—Numerous variations are described of a device consisting of a filter, e. g., a Buchner funnel, a stopcock attached to regulate the flow of filtrate from the device, an air-tight cover for the filter and a tube through the cover. During operation, the stopcock regulating the flow of filtrate also regulates the flow of liquid fed into the device as the air or other gas, e. g., N_2, trapped by the cover and the filter prevents flooding of the latter. Set-ups suitable for continuously and automatically washing ppts., filtering liquids or extg. solid substances are described. By making slight changes, suction can be used to speed up the process or for taking filtrate samples for testing. J. W. Perry

The production of parts for chemical apparatus from asbestos bakelite masses. V. Kikut. *Khim. Mashinostroenie* **1938**, No. 6, 42 3; *Khim. Referat. Zhur.* **2**, No. 5, 129(1939).—A mixt. of equal amts. of phenol and 40% formalin with NaOH as catalyst (0.2% of the wt. of phenol) was boiled until a resin sepd.; this was dried at 35–40° and then heated at 90° until the required viscosity was acquired. The resin was mixed with an equal quantity of asbestos to form "faolite." Fans for Cl ventilators were prepd. by shaping the mass in wooden molds, drying at 75–80° for 7–8 hrs., smoothing with a rasp, and coating with bakelite lacquer. The wt. of these fans was 5 5 kg. against 12 kg. for ceramic fans. They are stable to an atm. of moist Cl, less expensive, lighter and stronger and can be rotated at greater speeds than the ceramic fans. A large assortment of anticorrosive articles can be prepd. from the faolite mass, which can successfully replace the ceramic ware, metal, etc. W. R. Henn

Clad and lined equipment. F. P. Huston *Chem. Met. Eng.* **46**, 298–300(1939).—Vessels capable of withstanding corrosion and having ample mech. strength are constructed either by using thin sheets of the relatively expensive corrosion-resisting metal to form a lining attached to an already fabricated steel shell, or by fabricating it in a clad metal in which 5, 10, 15 or 20% of Ni, Monel, stainless steel, etc., is first attached to the mild-steel backing, and the whole then rolled down to form a composite sheet.
B. C. P. A.

Aluminum in the chemical industry. F. Sinigaglia. *Alluminio* **8**, 5–17(1939).—The advantages of Al as a material for chem. app. and containers are described and illustrated by examples of practical applications. The behavior of Al toward solns. of many inorg. and org. substances is summarized in tabular form. B. C. P. A.

Useful laboratory motor. J. H. Pickett. *Chemist-Analyst* **29**, 17(1940).—Directions are given for making a synchronous motor out of the motor of an elec. fan in which the rotor winding or the commutator has been damaged.
W. T. H.

Simple breakable seal. Philip I. Bowman. *Chemist-Analyst* **29**, 17–18(1940).—Directions are given for constructing a sealed tube in a U-tube so that after a vacuum has been established the seal can be broken by freezing a little liquid in it by means of a CO_2-toluene bath.
W. T. H.

Self-filling buret for alkaline solutions. Albert C. Nuessle. *Chemist-Analyst* **29**, 16(1940).—In the app. described, the alkali hydroxide soln. is contained in a large, wide-mouthed bottle. The bottle carries a rubber stopper with 3 holes. Through 1 hole a rubber tube extends to just below the bottom of the stopper and the outside end is attached to a rubber pressure bulb, such as is used in atomizers. The middle hole carries a narrow tube extending to the bottom of the bottle. Above the stopper there is connection to the side of a buret, a little below the lowest graduation, and a pinchcock prevents the back flow of liquid after the buret has been filled. The buret itself is inserted into the third hole in the stopper but the bottom of the buret is sealed so that liquid from the buret can drain by gravity only into the bottle when the intervening pinchcock is open, or into the titrating vessel through another side arm attached to the buret a little below the tubing through which the buret is filled. A hole in the glass tubing attached to the pressure bulb permits excess pressure to escape. W. T. H.

Field and laboratory microanalysis by means of a portable drop reaction kit. Philip W. West and Lothrop Smith. *J. Chem. Education* **17**, 139–45(1940).—See *C. A.* **33**, 7623[1]. J. E. D.

Weighing bottle. W. A. Taebel. *Ind. Eng. Chem., Anal. Ed.* **12**, 141(1940).—The bottle facilitates the transfer of finely divided, fluffy and liquid materials to volumetric flasks without loss, by combining a funnel with a bottle to form one compact unit. A. W. King

Ten-liter volumetric flask. Francis J. Reithel. *Ind. Eng. Chem., Anal. Ed.* **12**, 159(1940).—The flask consists of a 12-liter Pyrex bottle with a graduated pipet inserted through the stopper to measure large quantities of standard solns. to ±5 ml. A. W. King

All-glass ball-valve stirrer. Silvester Liotta. *Ind. Eng. Chem., Anal. Ed.* **12**, 173(1940).—A description of a construction suitable for all solns. that require a slow-motion (5 strokes per min.) having a pos. flow from bottom to top. A. W. King

Adjustable support for crucibles. H. C. Lockwood. *Analyst* **65**, 160(1940).—The support is made from small retort bosses which are cut in halves; 3 of these halves are used. The crucible or dish is supported on 3 points which can be removed cleaned or renewed The crucible or dish is held rigidly and the ring stand can be moved or tilted. There is a saving of gas for less heat is lost by radiation than when a clay or silica triangle is used.
W. T. H.

All-glass still with automatic float feed. Geo. F. Liebig, Jr. *Ind. Eng. Chem., Anal. Ed.* **12**, 174(1940).—A Cenco 500-w. giant elec. heater makes possible the production of 500 ml. of redistd. water per hr.; the process is continuous over long periods. It can also be used for redistg. nonaqueous liquids. A. W. King

Still for producing metal-free distilled water. J. S. McHargue and E. B. Offutt. *Ind. Eng. Chem., Anal. Ed.* **12**, 157–9(1940).—The authors use a thin-walled quartz condenser tube and steam from the central heating

plant to give 11 l. of metal-free distd. water per hr. at temps. of tap water, or 13 to 15 l. per hr. with condensate at 80 to 90°; the distillate contains 150 parts per billion of ignited total solids, mostly SiO_2 from the condenser tube and the Pyrex concg. flask. A. W. King

Plate-type distillation columns. James S. Carey. *Chem. Met. Eng.* **46**, 314–17, 336(1939).—The effect of plate spacing and the depth of the liquid seal on the permissible vapor velocities, and the shape and spacing of the bubble caps for various operating conditions, are discussed. The advantages of plate spacings of not less than 24 in. are stressed. B. C. P. A.

A valve accessory for control of frothing in vacuum distillations. Martin Burger. *Chemist-Analyst* **29**, 20–1 (1940).—In biochem. work, solns. or suspensions contg. proteins, carbohydrates and liquids are usually viscous and likely to entrap air when transferred to a distg. flask. The entrapped air often causes frothing during distn. This can be prevented by providing an extra piece of tubing which enters the distg. flask and extends about as far down as the distg. arm. When frothing takes place, a very little air introduced into the flask through a capillary will serve to stop it. W. T. H.

An easily controlled Johnson extractor. Laurence Griffith. *Chemist-Analyst* **29**, 23(1940).—A small vessel contg. the thimble is connected to the bottom of a 12-in. water-cooled condenser. The vessel is made from an ordinary test tube. The bottom has tubing sealed to it and leads to a weighing tube. Fifteen ml. of solvent is sufficient. W. T. H.

Diatomaceous silica as applied to filtration problems. F. G. Salmon. *Chem. Eng. Group, Proc. Soc. Chem Ind.* **20**, 20–30(1938).—The selection and use of diatomaceous filter aids are considered generally. B. C. P. A.

New construction methods for filters and centrifuges. Hans H. Hülsen. *Z. Ver. deut. Ing., Beiheft Folge* **1939**, No. 6, 187–95.—A variety of filters and centrifuges is described. Karl Kammermeyer

Directly air-driven transparent ultracentrifuges. J. W. McBain and A. H. Lewis. *J. Phys. Chem.* **43**, 1197–1205 (1939); cf. *C. A.* **29**, 3198[6].—The details of two ultracentrifuges are described. One has a stationary periscope and the other has built-in mirrors It is pointed out that there is no theoretical difference between cells of different dimensions provided that the resolving power is kept const. H. E. Phipps

Apparatus for the determination of small amounts of hydrocarbons in air. M. V. Aristarkhova. *Azerbaidzhanskoe Neftyanoe Khoz.* **1939**, No. 7, 15–18.—Translated in *Foreign Petroleum Tech.* **7**, 383–90(1939).—Description of an app. operated by combustion, absorption with C and cooling with liquid O. The app. is suitable for soil-gas analysis after a few modifications. A. A. B.

Introduction to liquid mixing. A. Brothman and H. Kaplan. *Chem. & Met. Eng.* **46**, 633–6, 639(1939).—By test procedures described, the work necessary to achieve a given level of mixing can be divided into the mech. work that must be supplied by the mixer and the "latent work" of the system. "Latent work" is described as the counteraction of the forces of cohesion within the various components of a mixing system, or it may consist of an establishment of a bond between dissimilar particles comprising the mixing system. Various mixing systems differ in proportion of these 2 kinds of work for a given case. Curves are given to predict the power requirements for mixing by the use of an indirect and a direct shear ratio. R. M. Boarts

Magnetic shaking device. S. Kiyomizu. *Ind. Eng. Chem., Anal. Ed.* **12**, 174(1940).—The device consists of an iron rod pulled in and out of the coil of an electromagnet, operated by 50 v. d. c. and an elec. flasher button. The agitator holds six 250-cc. glass-stoppered Erlenmeyer flasks on a swinging platform. A. W. King

Apparatus for reduction-oxidation determinations. H. Eggers and Hans Mohr. *Biochem. Z.* **302**, 211–19(1939). —Description of the app. S. Morgulis

An apparatus for making reduction-oxidation measurements in vacuo. Holger Jørgensen. *Biochem. Z.* **302**, 226–31(1939).—Description of an app. which is supposed to offer certain advantages over other types together with some exptl. data on such detns. in fruit and plant juices. S. Morgulis

Flow divider for gases. Johannes H. Bruun. *Ind. Eng. Chem., Anal. Ed.* **12**, 172(1940).—A satisfactory device for lab. purposes is described. It is based on the principle used in the adjustable orifice flowmeter in which the resistance of a capillary tube to gaseous flow is varied by inserting wire. Calibration curves are shown for gas rates varying from 1 to 5 l. per min. A. W. King

Acceleration of the sedimentation of industrial suspensions. V. R. Terashkevich, R. I. Baranova and L. Ya. Anikeeva. *J. Applied Chem.* (U. S. S. R.) **12**, 1022–31 (in French, 1031)(1939).—The velocity of sedimentation depends on the form and dimensions of the sedimentation vessels. Math. relations are derived that show that the effectiveness of the suspension vessel, in general, is proportional to the sum of the areas of horizontal projections of all interfaces between suspension and wall of the vessel and suspension and air. These math. deductions were experimentally confirmed. The effectiveness of cylindrical sedimentation tanks can be increased by installing addnl. slanted wood surfaces. A. A. Podgorny

Separation of mixtures of gases by adsorption. V. N. Alekseev. *J. Applied Chem.* (U. S. S. R.) **12**, 995–1005 (in French, 1005)(1939).—The binary mixts. O_2-N_2, CH_4-N_2 and N_2-H_2 were studied at 14–20°; the adsorbent was activated carbon "KU-8." The components which had nearly the same sorption coeffs. were the hardest to sep., and those which had very different sorption coeffs. were the easiest to sep. A. A. Podgorny

A modified Kendall tube for purifying nitrogen. G. M. Savage and Z. John Ordal. *Science* **91**, 222–3(1940). The improved tube is packed with a roll of Cu gauze tightly wrapped around a Calrod heating unit. Earl H. Brown

Generator for air-free carbon dioxide (or hydrogen S. Horwood Tucker. *Analyst* **64**, 410–15(1939).—The construction of the app., the prepn. of air-free reagents and the manipulation and testing of the generator are described. B. C. P. A.

An improved rotary viscometer. A. H. Nissan, L. V. W. Clark and A. W. Nash. *J. Sci. Instruments* **17**, 33–8 (1940).—A rotary viscometer with provision for cylinder alignment, control of end effects and speed and temp control is described and illustrated. Results are reported Earl H. Brown

Vacuum cooling installations. Theoretical principles and installations for heat exchange. Ernst Bergener *Z. Ver. deut. Ing., Beiheft Folge* **1939**, No. 5, 140–8. A summary of the principles with sample calcns. of installations in a KCl plant. Diagrams and data are given. Karl Kammermeyer

Recovery of the volatile solvents by means of solid sorbents. IV. Sorption and desorption of chlorine-containing organic solvents by active carbon. E. V. Alekseevskiĭ and Ya. D. Musin. *J. Applied Chem.* (U. S. S. R.) **12**, 704–18(in German, 719)(1939); cf. *C. A.* **31**, 2047[8]. The adsorption isobars for $(CH_2Cl)_2$, $CHCl{:}CCl_2$, $CHCl_3$ and CCl_4 by granulated active carbon "AG," birch charcoal (steam-activated) and fruit-pit charcoal (activated by $ZnCl_2$), were obtained and their adsorption isotherms were calcd. for 20°. The first and last adsorbent produced the best results. An investigation of dynamics of adsorption and catalytic action of carbon on the decompn. of the Cl-contg. org. compds. showed that it is practicable to recover the above solvents by adsorption with active carbon and desorption with superheated steam. 26 references. A. A. Podgorny

Solvent extraction and absorption. Werner Matz. *Z. Ver. deut. Ing., Beiheft Folge* **1939**, No. 6, 198.—A correction (cf. *C. A.* **34**, 4[3]). Karl Kammermeyer

Basic principles of mass transfer in rectification, extraction and absorption. Werner Matz. *Z. Ver. deut Ing., Beiheft Folge* **1939**, No. 5, 155–62.—A discussion of the thermodynamic principles and their application to the various processes as well as of the problems involved in

the carrying out of continuous processing. Diagrams and 27 references. Karl Kammermeyer

Cold-extraction apparatus. Joseph Benotti. *Science* 91, 223–4(1940).—By means of a system of valves and a lever the extractant is caused to circulate between soln. and solvent. Earl H. Brown

Fractionating apparatus of light construction. J. N. Belsen. *Oel, Kohle, Erdoel, Teer* 15, 363–6(1939).—The use of Al or enameled Fe in place of cast Fe for columns for C_6H_6 hydrocarbons is described. B. C. P. A.

High-temperature camera for Debye-Scherrer photographs. W. Borchert and K. Fishbeck. *Z. Physik* 114, 515–18(1939).—Details are given and general applicability is claimed. E. J. Rosenbaum

Method of estimation of air distribution in flotation machines. V. I. Klassen. *Tsvetnye Metal.* 1939, No. 7, 76–9.—An apparatus is described whereby a sample of pulp can be taken at any point in the flotation machine and the air content detd. automatically. Graphs are given illustrating results of tests. B. N. Daniloff

Wetting and flotation in connection with the problem of the transition layer. P. A. Rebinder. *Trans. Faraday Soc.* 36, 295–305(1940).—The influence of flotation reagents was studied by employing a method which is based on measuring the changes in the wettability produced. The wetting isotherms are given for oxidized and polished Ag, Pt and Cu surfaces in aq. solns. of Na oleate and for Au surfaces in aq. solns. of K Bu xanthate. The adhesion of air bubbles to covellite in an aq. soln. of K Bu xanthate is presented, as well as the kinetics of the adsorption and the role of the elec. double layer in flotation. V. R. D.

Bumping of solutions. J. E. Edwards. *Chemistry & Industry* 1940, 152.—Bumping can be prevented by holding a piece of Whatman No. 531 filter paper against the bottom of the beaker by means of a glass rod, the other end of which rests against the side of the beaker. G. G.

Corrosion in water-heating apparatus. Fritz Gunewig and Karl Trapp. *Gesundh.-Ing.* 61, 687–90(1938).—Corrosion in high-pressure app. can be avoided by installing air- and O-absorbing devices and using paints contg. cement and water glass. B. C. P. A.

Pipe-line calculations. H. Vernon Smith, Clifford H. Brady and I. W. Donnell. *Oil Gas J.* 38, No. 40, 44, 45, 47(1940).—An extensive discussion of fluid flow problems encountered in pipe-line design. Charts and examples given. W. Andrew Wright

Storage and reaction vessels. Charles O. Brown. *Chem. & Met. Eng.* 46, 310–13(1939).—Points to be considered in the design of welded steel vessels with or without covers and jackets are discussed. B. C. P. A.

Packed and spray-type contactors. Z. G. Deutsch. *Chem. & Met. Eng.* 46, 318–21, 336(1939).—It is pointed out that large gas-liquid interface area may be provided by means of sprays or bubbling, wetted-wall or packed towers, the choice depending on the presence or absence of impurities in the gas and liquid, the speed of reaction, etc. B. C. P. A.

Designing heavy rotary equipment. W. S. Dickie. *Chem. & Met. Eng.* 46, 326–9, 333(1939). It is suggested that since the local stresses occurring in rotary kilns and dryers are unpredictable, the shells cannot be designed as beams, etc., but must be based on previous experience with such app. B. C. P. A.

The optimum heat arrangement and a general method of the layout of evaporators. N. A. Ushatinskii. *Khim. Mashinostroenie* 1938, No. 4, 3–10; No. 5, 3–12; *Khim. Referat. Zhur.* 2, No. 5, 127–8(1939).—A general method for the layout of evaporators is given in a full and in a simplified form. The arrangement is detd. by the physical and chem. properties of the evapd. soln. The conditions for detg. the no. of stills and of the pressure of the steam are described. A no. of examples are given. The information is of value for the layout of multistill evaporators. W. R. Henn

How a long-tube evaporator works. W. L. Badger. *Chem. & Met. Eng.* 46, 10, 640–1(1939).—Five stages of operation with increasing ΔT can be distinguished. They are: Simple sensible heat exchange, slow simmering, ejection of slugs of liquid and puffs of steam, emission of a crown of slow-moving drops of liquid with a jet of steam contg. entrained liquid occupying the core of the tube, and production of a stream of steam contg. a suspension of fine particles of liquid traveling at high speed. Everything else being equal, the heat-transfer coeff. in the boiling section of the tube is greater at smaller temp. drops. It would appear more important to drown the heating surface with relatively large amts. of liquid than to depend on high velocity to wipe off the steam bubbles. The relationships between length of tube, ΔT, length of boiling section and coeff. of heat transfer are still not adequately detd., and exact statements as to the ranges in which the important last 3 stages occur cannot yet be made. R. M. Boarts

Development of drum drier with an air exhaust and of quick drier. B. Sägebarth. *Centr. Zuckerind.* 48, 51–2(1940).—Mech. features. W. W. Binkley

Calculation of the time of cooling and heating of apparatus. I. G. Malkiel. *Khim. Mashinostroenie* 1938, No. 5, 32–4; *Khim. Referat. Zhur.* 1939, No. 5, 131–2.—The amt. of heat (Q' in cal./hr.) given off or absorbed by a metal wall from contact with liquid or gas of a const. temp. in the first τ hrs. is $Q' = gc(t_0 - t_M)f(a\tau/x^2, ax/\lambda)$, where g is the wt. of the metal in kg., c the heat capacity in cal./kg., t_M the initial temp. of the metal, t_0 the temp. of the liquid, $f(a\tau/x^2, ax/\lambda) = Q'/Q$ the function of the criteria of Biot (B) and of Fourier (F). Values of $1/F$ are plotted against the log of the function f. With the help of this diagram it is possible to solve problems on heating and cooling of substances for values of B from 0.1 to 0.003 for unlimited values of F construction of the diagram is explained and examples for the calcns. of the time of cooling are given. W. R. Henn

Automatic control of temperature at Convent Garden Laboratory. J. K. Hardy. *Dept. Sci. Ind. Research* (Brit.), *Rept. Food Invest. Board* 1938, 264–5(1939).—Thermostatic control of heat alone has the disadvantage that the relative humidity fluctuates. Direct and automatic controls regulate the temp. of the brine in the cooler-circuit of each chamber; this results in an increase in relative humidity to between 85 and 90%. Each chamber has a sep. circulating pump which maintains a full flow of brine through the cooler. The temp. is const. within ±0.1 deg. F. J. S. Hicks

Automatic control of furnace atmospheres. H. M. Webber. *Instruments* 13, 73–6(1940).—A review. E. H.

The measurement of temperature and flow in furnace systems. A. H. Leckie. *Fuel* 19, 20–3(1940).—A new suction pyrometer and water-cooled Pitot tube that permits measurement of temp. and velocity in furnace passages, is described; temps. to 1550° may be detd. Although waste-gas temps. in flues below the checkers may be detd. by an exposed thermocouple without serious error, that method will not give true temps. of affluent air. The partition and stratification of flow in open-hearth furnace uptakes was measured. D. A. Reynolds

Inexpensive immersion heater. Karl S. Willson. *Chemist-Analyst* 29, 18–19(1940).—The heating element consists of coiled resistance wire inserted in glass tubing. W. T. H.

Heat problems in the rectification of binary mixtures. B. I. Bondarenko. *Neftyanoe Khoz.* 1939, No. 9, 43–5.—Calculations. A. A. Boehthingk

Expansion of liquids by heat. Wilhelm Bahrdt. *Z. physik. chem. Unterricht* 52, 223–6(1939).—A 500-ml. flask, and a three-hole rubber stopper fitted with a thermometer, a graduated capillary tube to measure expansion, and a closed tube or rod which may be moved to adjust the initial reading constitute the app. Data in tables and graphs, and equations for the expansion of H_2O in its various temp. ranges are presented, and also a paragraph on other liquids. F. E. Brown

The effect of air in heating steam upon the heat transfer in heat exchangers. K. Jaroschek. *Z. Ver. deut. Ing., Beiheft Folge* 1939 No. 5, 135–40.—Expts. on a water preheater showed that with an air content of 2 to 7.4% in the

steam fairly high heat-transfer coeffs. could still be obtained. Satisfactory coeffs. were observed up to 46% air, which, however, necessitated high steam losses by venting. The reported values hold for the exptl. conditions only and the decrease of the coeffs. will be more or less for higher or lower mean water temps., resp. The results cannot be applied to vaporizing conditions where the effect of air is much more pronounced. 7 references.

Karl Kammermeyer

Cost relations of heat exchangers. E. N. Sieder. *Chem. Met. Eng.* **46**, 322-5(1939).—The effects on the cost of heat exchangers of tube diameter, tube length, working pressure, no. of floating heads, and area exposed are stated, and it is pointed out that repair and maintenance charges may make higher capital outlay desirable.

Low-temperature distilling and carbonizing apparatus suitable for treating wood, bones, etc. Paul Hadamovsky. U. S. 2,186,169, Jan. 9. Various structural details.

Vacuum crystallizing or cooling by forced boiling. John W. Dudley, Jr. U. S. 2,185,940, Jan. 2. Various details of app. and operation.

Pressure-reducing apparatus suitable for use with high pressures. Paulsen Spence. U. S. 2,185,713, Jan. 2. Various structural, mech. and operative details.

Apparatus (with a flexible-diaphragm-controlled valve) for pressure regulation, such as that of steam, etc. James L. Kimball (to Ruggles-Klingemann Mfg. Co.). U. S. 2,185,671, Jan. 2. Various structural and operative details.

Dephlegmator with horizontal tubes. A. L. Malchenko and A. F. Berenshtein. Russ. 56,014, Nov. 30, 1939. Construction details.

Tube for introduction of oxygen into liquid metal. N. S. Fortunatov and E. B. Gitman. Russ. 56,111, Nov. 30, 1939. The outer refractory cover of the tube consists of a mass of magnesite, alumina and C.

Filtering apparatus. V. P. Sabbatovskiĭ. Russ. 55,848, Oct. 31, 1939. Mechanical features.

Filler block for filter presses. Thomas E. Raymond. U. S. 2,185,314, Jan. 2. Various structural and operative details.

Automatic control apparatus for backwashing water filters, etc. Joseph P. Lawlor. U. S. 2,184,618, Dec. 26. Various structural and operative details.

Elastic belt for vacuum filters. A. F. Fogt, I. I. Karataev, P. F. Derevitskiĭ and I. A. Ish. Russ. 55,887, Oct. 31, 1939. Construction details.

Self-cleaning apparatus for atomizing liquids such as water for humidification. Herman F. Simon (to Parks-Cramer Co.). U. S. 2,186,214, Jan. 9. Various structural, mech. and operative details.

Centrifugal separator suitable for separating solids from liquids. Geo. J. Strezynski (to De Laval Separator Co.). U. S. 2,185,279, Jan. 2. Various structural details.

Trough for the separation of coarse from fine suspension. L. P. Safronyuk. Russ. 55,907, Oct. 31, 1939. Construction details.

Water-spray apparatus for removing dust from air in a treating conduit. Samuel B. Roberts (to Celanese Corp. of America). U. S. 2,186,125, Jan. 9. Various structural and operative details.

Device suitable for indicating the density of the air. Guy E. Beardsley, Jr., and John S. Hasbrouck (to United Aircraft Corp.). U. S. 2,185,578, Jan. 2. Various structural, mech. and operative details.

Rotary impeller pump for air or other gases, etc. Ernest C. Hassler (to Roots-Connersville Blower Corp.). U. S. 2,185,338, Jan. 2. Various structural, mech. and operative details.

Apparatus for gas analysis. E. M. Korolev. Russ. 55,958, Oct. 31, 1939. An app. for elec. detn. of gases in air is described.

Apparatus for the automatic control and regulation of the composition of gas. A. B. Ut'yan. Russ. 56,011, Nov. 30, 1939. The app. contains 2 chambers, one filled with a standard gas and the other with the gas to be tested. Elec. discharges are passed through each chamber and the intensities of sparks are compared by means of a photocell and recording devices.

Gas container suitable for use with carbon dioxide, etc. Daniel K. McInnis and Robert B. Aldrich. U. S. 2,185,796, Jan. 2. App. is used having a main compartment and a reserve compartment, a tube having ports communicating with the reserve and main compartments, a conduit communicating with the tube, and a valve in the tube, the valve having ports adapted to register with the tube ports to connect the main compartment with the conduit in one position and the reserve compartment with the conduit in another position while disconnecting the main compartment from the conduit.

Reducing valve, suitable for controlling the flow of fluids. Ferris T. Harrington (to Vickers, Inc.). U. S. 2,184,670, Dec. 26. Various structural and operative details.

Device for sampling powders such as face powders. Joseph E. Valentine. U. S. 2,185,586, Jan. 2. Various details of a device formed with use of a thermoplastic material which is adhesive when heated.

Mixing powders with liquids, as in preparing "regenerated milk," dispersing barytes in latex or paint vehicles. John L. Milton. U. S. 2,186,033, Jan. 9. Various details of a centrifugal mixing app. and its operation.

Apparatus for agitating materials such as light, fluffy carbon black. Howard W. Price (to J. M. Huber Corp.). U. S. 2,185,158, Dec. 26. Various details are described of a rotary drum app. with a plurality of compartments in each of which a single weighted roller is placed.

Apparatus for measuring diffusion speeds. Haardt & Co. A.-G. Brit. 508,837, July 6, 1939. The speed of diffusion of fluids, e. g., H_2O, in viscous or solid substances, e. g., bitumen or lacquer, is measured by means of dielec. properties, the substance being introduced between the electrodes of a condenser in which the intermediate spaces between the electrodes are closely covered on the side(s) to be exposed to the fluid with porous, preferably ceramic material, the covering advantageously being extended to form a hollow body for reception of the condenser electrodes with the substance to be measured or the fluid to be diffused therein. The results are of value in considering the question of corrosion, e. g., the resistance of constructional materials to weather and moisture.

Hydraulic classifiers. Rupert O. Stokes and Wm. D.

J. Thomas. Brit. 509,020, July 10, 1939. Classifiers of the hindered settling type provided with a valve for continuous discharge of the larger or heavier solids have an arrangement for adjusting the degree of opening of the valve in dependence on the effective head of the column of tectering solids comprising a chamber subjected to hydraulic pressure, an operating connection between the valve and a part of the wall of the chamber movable in response to a change of pressure therein, means for retarding any movement of the wall part by any force acting on the valve and means for varying the hydraulic pressure in dependence on the effective head of tectering solids.

Apparatus for cooling the air by evaporation of water sprays. Everett B. Evleth (to Minneapolis-Honeywell Regulator Co.). U. S. 2,184,613, Dec. 26. Various details of an app. with thermostatic and humidity-actuated controls.

Dehydrating screen. P. G. Dremailo. Russ. 52,244, Dec. 31, 1937. Mechanical features.

Evaporative condenser suitable for air-conditioning apparatus. Lee W. Melcher (to Waukesha Motor Co.). U. S. 2,185,035, Dec. 26. Various structural and operative details.

Drying laminated sheets of vulcanized fiber. Norman G. Jones (to Continental-Diamond Fibre Co.). U. S. 2,185,087, Dec. 26. A method of preventing cracking and delamination involves preliminarily drying the interior of the sheet while contg. an aq. moistening agent at the side edges.

Grinding mills. H. J. & A. Coulthurst Ltd. and H. Coulthurst. Brit. 508,877, July 7, 1939. Mills of the edge-runner type for the grinding of paint, etc., have the runner driven by bevel gears from a driven sleeve rotatable about and movable vertically upon a stationary shaft disposed centrally of the pan.

Crushing, grinding and amalgamating mills. Taymer Mill Pty. Ltd. Brit. 509,091, July 11, 1939. A roller is set at an angle to the vertical in a horizontal pan whereby the circular spherically convex face on the bottom of the roller comes into contact with the inside bottom face of the pan at a point just outside its true axial center giving a circle of contact concentric with its axis during rotation, and whereby the peripheral face parallel with the axis of the roller touches the inside upwardly extending face of the pan.

Gyratory crushing mill suitable for ores, etc. John W. Stevens (to Fuller Corp.). U. S. 2,185,528, Jan. 2. Various structural, mech. and operative details.

Charging device for sintering apparatus. Metallgesellschaft A.-G. Brit. 508,930, July 7, 1939. The device consists of an endless box band in which the boxes consist only of 3 walls, the wall transverse to the endless band being secured to the band.

Apparatus for breaking bulk material, e. g., coke, coal, into smaller pieces. Fried. Krupp A.-G. Brit. 508,922, July 7, 1939. The constantly moved support for the material is constituted by a bar or roller grate or by a shaking screen, the material thereon being exposed to a regulatable impact action by means of a plurality of impact members arranged in series and arranged to fall freely onto the material under gravity.

Effecting heat transfer. Arthur A. Levine and Oliver W. Cass (to E. I. du Pont de Nemours & Co.). U. S. 2,185,639, Jan. 2. Nuclear chlorinated ethylbenzene contg. at least 3 atoms of Cl per mol. of ethylbenzene is heated (suitably to 100–310°) and then used for heating materials such as oils or steam, by indirect heat transfer.

Heat-exchange apparatus. Bennet C. Shipman (to Servel, Inc.). U. S. 2,184,759, Dec. 26. Various structural details.

Heat-exchange apparatus suitable for air-blast heating or cooling. Fred M. Young. U. S. 2,184,657–8, Dec. 26. Various structural details.

Heat-exchange apparatus suitable for condensing refrigerants by water cooling. Edward R. Wolfert (to Westinghouse Elec. & Mfg. Co.). U. S. 2,186,224, Jan. 9. Various structural details.

Heat-exchange apparatus suitable for continuous absorption refrigerating systems. Rudolph S. Nelson (to Hoover Co.). U. S. 2,185,001, Dec. 26. App. used comprises a plurality of nested cup elements, conduit elements projecting from each side of each of the cups, means connecting the conduit element projecting inwardly of each cup with a conduit element projecting outwardly of another cup, the conduit elements of each cup being spaced 90° from the corresponding conduit elements on adjacent cups, and a baffle plate positioned within each of the nested cups.

Float hydrometer with an indicator-corrective device for temperature variations. Charles E. Linebarger (to Chaslyn Co.). U. S. 2,185,205, Jan. 2. A thermostatic bellows and an indicator within the hydrometer are connected together.

High-temperature thermostatic devices suitable for controlling flow of heating fluids. Carl F. Prutton and John T. Marvin (to Patrol Valve Co.). U. S. 2,185,421–2, Jan. 2. Liquids such as a chlorinated biphenyl or chlorinated diphenyl oxide are used for filling devices such as valve-control bellows for operating by their expansion when heated.

Air-conditioning system utilizing calcium chloride or the like for dehumidification. Hiram J. Kaufman. U. S. 2,184,998, Dec. 26. Various details of app. and operation are described.

Absorption refrigerating system suitable for use with ammonia solution and hydrogen. Hugo M. Ullstrand (to Servel, Inc.). U. S. 2,184,726, Dec. 26. Various structural and operative details.

Refrigerating process suitable for use with ammonia, etc. Harry F. Smith and Charles E. Waring (to General Motors Corp.). U. S. 2,185,040, Dec. 26. A process is used which involves absorbing a gas such as NH_3 into a liquid such as triethanolamine and chemically absorbing the gas from the liquid into a solid, such as $SrCl_2$, colloidally suspended in the liquid and then driving the gas from the solid into the liquid and then out of the liquid (the solid and liquid used being chemically inert to each other, and the liquid remaining unvaporized throughout the absorbing and generating cycles).

Air-cooled rectifier for absorption refrigerators. Curtis C. Coons (to Hoover Co.). U. S. 2,184,991, Dec. 26. Various details of thermostatic control, etc., are involved in this patent and U. S. 2,184,992. U. S. 2,184,993 relates to the use together in a refrigerating system of NH_3 and methylamine, a solvent comprising monoethanolamine, and a gaseous substance such as H or N which is inert to NH_3 and methylamine and which has a common chem. constituent therewith and with the solvent.

Oceanographic observations from the surface in the Atlantic and Pacific Oceans. J. Rouch. *Bull. inst. oceanograph.* No. **781**, 16 pp.(1939).—The d. of ocean water as detd. by R. is recorded as $(\Sigma_t - 1)1000$, in which Σ_t is the d. at $t°$. The salinity is recorded as salinity per 1000 parts, and was detd. from the d. The pH was observed with the aid of cresol red indicator. Water samples and tests were taken at intervals between Havre and San Francisco via the Panama Canal. At 50° N. lat. the Atlantic water temp. was 15°, at 35° N. lat. 24°, at 22.5° N. lat. 28.5°, and at 9° N. lat. nearly 31°. South of 22.5° N. lat. the Atlantic water temps. were lower than the temps. at corresponding Pacific N. lats. At 22.5° N. lat. the Pacific water temp. was 28.5° near the coast of Salvador. In the Atlantic the salinity reached a max. of nearly 37.5 parts per thousand at 26.5° N. lat., whereas in the Pacific the max. was 35 parts per thousand at 22° N. lat. The water pH was a max. of 8.25 at 39° N. lat. in the Atlantic and 8.26 at 20° N. lat. in the Pacific. The Atlantic water temp. is consistantly higher than the corresponding air temp. Relative humidity in both oceans averaged approx. 80%, varying from 67 to 88% in the Atlantic Ocean and from 86 to approx. 70% with values of 54 and 60% in rare locations, in the Pacific Ocean portions of the voyage. At Curacao (S.A.) the humidity was recorded as 94%. H. E. M.

Contribution of diatoms to the sediments of Crystal Lake, Vilas County, Wisconsin. Paul S. Conger. *Am. J. Sci.* **237**, 324–40(1939).—This soft-water lake exhibits an unexpected diversity both in biol. stratification and in horizontal distribution of diatoms in its sediments. Diatoms, of which 23 genera and 85 species are tabulated, and pine pollen are the chief constituents of the sediments. Chem. analyses of the lake water at different depths are recorded. B. C. P. A.

Tenth report of the committee on atomic weights of the International Union of Chemistry. J. P. Baxter, M. Guichard, O. Hönigschmid and R. Whytlaw-Gray. *J. Am. Chem. Soc.* **62**, 609–72(1940).—The report covers the twelve-month period September 30, 1938, to September 30, 1939. Three changes in the table of at. weights were adopted; they are H, from 1.0081 to 1.0080, Fe from 55.84 to 55.85 and Lu, from 175.0 to 174.99. Data are presented on the completeness of sepn. of the isotopes of Cl in HCl samples subjected to isotopic sepn. by the thermal diffusion method. The relative abundances of the Mo, Eu and Pb isotopes are discussed. Also in *Ber.* **73A**, 39–43. A. B. Garrett

The second virial coefficient of ethane. Edwin E. Roper. *J. Chem. Phys.* **8**, 290(1940).—Eucken and Parts (*C. A.* **27**, 2359) have not used the formula which they presented for the value of *B* for the calcns. in their table. The formula that they did use is deduced. There are differences of 2.6–8% between the 2 formulas. G. M. Petty

The structure of phosphine and related hydrides. D. P. Stevenson. *J. Chem. Phys.* **8**, 285–7(1940).—Badger's rule (*C. A.* **28**, 2996⁶) when applied to the frequencies of some hydrides gives values for the interat. distances that agree well with values deduced from the moments of inertia of the hydrides and with values predicted from the covalent radius of H, 0.315 A. With the value 1.415 A for the P-H distance in PH_3 and a reliable spectroscopic value for one of the moments of inertia of the mol. the bond angle is found to be 93°. Bond angles and at. distances are estd. for SiH_4, GeH_4, AsH_3, SeH_2, SnH_4, SbH_3 and TeH_2. G. M. Petty

Partition functions and energy levels of molecules with internal torsional motions. Bryce L. Crawford, Jr. *J. Chem. Phys.* **8**, 273–81(1940).—Math. The complete energy matrix is set up for external and (hindered) internal rotations of "pseudo-rigid" mols., i. e., mols. consisting of a rigid framework to which symmetric hindered rotators are attached. G. M. Petty

Theory of the Senftleben effect. F. Zernike and C. van Lier. *Physica* **6**, 961–71(1939)(in English).—By means of a new formulation of the probability of collision a quant. elaboration is presented of Gorter's (*C. A.* **32**, 6119⁹) explanation of the S. effect, namely the shortening of the mean free path by magnetic precession between collisions. The calcns. for the heat cond., with the magnetic field oriented in different ways to the temp. gradient, are in good agreement with expt. Viscosity calcns., on the basis of the elementary theory, are 50% too low. G. W. King

Color and magnetic properties of manganous sulfide Shanti S. Bhatnagar, Brahm Prakash and Jarnail Singh *J. Indian Chem. Soc.* **16**, 313–20(1939).—Samples of the pink MnS were prepd. by 2 different methods, and specimens of the green variety were produced by 3 independent processes. The susceptibility of each sample was detd. by the Gouy magnetic balance at 6 temps. from 34° to approx. 240°. For the pink MnS the susceptibility ($\times 10^6$) is 41.85 at 34° and 35.85 at 245°. The Curie-Weiss law is followed in this temp. interval with $\theta = -910°$. The magnetic moment is 5.95–6.02 Bohr magnetons. The specimens of the green variety also follow the Curie-Weiss law, with the Bohr magneton no. = 5.99–6.01. However, $\theta = -495°$ and the susceptibility ($\times 10^6$ is 64.15 at 34°, decreasing to 50.96 at 237°. Since the 2 types of lattice—cubic B_3 and hexagonal B_4—which occur in the pink variety have essentially the same susceptibility, it is suggested that the differences in color and susceptibility are probably due to differences in the types of linkage involved. W. W. Stifler

Measurement of the magnetic permeability of iron and permalloy by a new method in very weak fields of a high frequency. L. N. Loshakov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1540–7(1939).—The magnitude of the skin effect depends on the magnetic permeability μ of the material. If the skin effect is detd. by measuring the resistance of a metal in a high-frequency field, it is possible to calc. μ. The μ of Fe wire is almost independent of its diam. (0.1 to 0.5 mm.) and the frequency (7×10^6 to 23×10^6 cycles). The μ of permalloy band is smaller than that of Fe and also

independent of the frequency. After annealing the μ of permalloy increases about tenfold and rises with rising wave length. J. J. Bikerman

Active iron. XIII. Measurements on complex iron cyanides in solution. Arthur Simon and H. Knauer. *Z. Elektrochem.* **46**, 13-25(1940); cf. *C. A.* **34**, 1269[1].—The magnetic properties of solns. of $K_3Fe(CN)_6$, $K_4Fe(CN)_6$, and $Na_4[Fe(CN)_5AsO_2]$ in dil. *perchloric acid*, degassed H_2O, and neutral H_2O were detd. The *susceptibility* of the paramagnetic salts is less in soln., whereas *diamagnetism* increases. The *ferricyanides* in particular show marked recession of mol. susceptibility. After a few days, there is a deposit of what is probably $Fe(OH)_3$, which does not increase beyond a certain quantity and is believed to be due to the presence of small quantities of simple Fe^{+++} salts in the complex. Const. magnetic values are obtained only after 60 days. The results show that the secondary dissocn. of $K_3Fe(CN)_6$ leads to a Fe^{+++} 3 concn. which does not reach the ion and soly. product of $Fe(OH)_3$. The authors believe that the change in the *paramagnetism* of $K_3Fe(CN)_6$ is predominantly chem. rather than phys. $K_4Fe(CN)_6$ solns. undergo many and complex changes, difficult to explain. One of these is indicated by the equation $K_4[Fe(CN)_6] + 2H_2O \rightarrow K_3[Fe(CN)_5.H_2O] + KOH + HCN$. The change in diamagnetism of complex cyanides on soln. attains values as high as 20%. It is very improbable that the "*Stark-Effekt*" is responsible for this, but it is more likely due to such chem. changes as are produced by hydrolysis, dissocn., hydration, polymerization, action of light. In any case, detn. of fine differences in secondary dissocn. of complexes by magnetic methods is not possible without knowledge of the various chem. changes that take place on soln. and ageing of these complexes. H. Stoertz

Ferromagnetic domains and the magnetization curve. Wm. Fuller Brown, Jr. *J. Applied Phys.* **11**, 160-72 (1940).—A review describing the basic ideas of the domain theory. S. L. Gerhard

Influence of elastic and residual deformations on the galvanomagnetic effect in ferromagnetic bodies. K. P. Belov and D. I. Volkov. *J. Tech. Phys. (U. S. S. R.)* **9**, 1289-99(1939).—The galvanomagnetic effect (i. e., the change ΔR of the elec. resistance produced by a magnetization I) in Ni wires is intensified by stretching the wires. At medium tensions ΔR is large and proportional to I^2; at high tensions it diminishes again, owing to a non uniform distribution of internal strains. Plastic stretching of Ni wires lowers their ΔR, in the point of magnetic satn. it is 5% less than for annealed Ni. J. J. Bikerman

An absolute method for the dielectric constant and the loss in liquids based upon decimeter waves. M. A. Duvalkovskii. *Compt. rend. acad. sci. U. R. S. S.* **24**, 433 (1939) (in French).—The dielec. const. of a liquid can be measured by placing a thermometer filled with the liquid in an alternating elec. or magnetic field. EtOH and PrOH show dispersion between wave lengths of 18.4 cm. and 414 cm. No dispersion was observed with MeOH or 0.05% NaCl. M. Bradford Stone

Dielectric constant of water vapor at a frequency of forty-two megacycles. Angus C. Tregidga. *Phys. Rev.* **57**, 294-7(1940).—A heterodyne between a crystal-controlled oscillator and a tuned circuit, in the condenser of which the H_2O vapor was held, was used for measurements. Values were: at 71.9°, 1.0071; 99.8°, 1.0060; 147°, 1.00475. Gregg M. Evans

The dielectric constants of some pairs of diastereomers. Saul Winstein and Reuben E. Wood. *J. Am. Chem. Soc.* **62**, 548-51 (1940).—The dielec. consts. of the 2,3-diacetoxybutanes, 2,3-diacetoxypentanes, 3,4-diacetoxyheptanes, 2,3-dibromobutanes, 2,3-dibromopentanes, 3,4-dibromohexanes and 2-acetoxy-3-bromobutanes were measured; a table of these values and the values of d_4^{25} and n_D^{25} is given. The dipole moments were estd. by means of the Onsager equation (cf. *C. A.* **30**, 7002[7]); the values of dielec. consts. and dipole moments for the *meso* and *erythro* compds. are compared with those for the corresponding *dl* and *threo* isomers. It is concluded that, in general, the members of a pair of diastereomers differ 7 sufficiently in their dielec. consts. for these values to be useful for analytical purposes. A. B. Garrett

Dielectric properties of glycerides.* II. B. V. Bhide and R. D. Bhide. *J. Univ. Bombay* **8**, Pt. 3, 220-34 (1939); cf. *C. A.* **33**, 4482[2].—The dielec. consts. (D) of monomyristin (I) and monostearin (II) at 1000 and 5700 kilocycles are detd. at various temps. For a mixt. of the α and β forms of I (III) D is 2.43 at 25°, which is considerably smaller than that for the liquid (6.2 at 58°). When 2 III is kept for 4 days, D decreases to 2.3 at 25° because of the transformation of the α-form into the stable β-form, indicated by the increase of the m. p. (70.5°). When III is chilled, forming a glass-like product (IV) D (4.38 at 25°) is much higher than that of the β-form; this indicates a condition similar to a supercooled liquid. Raising of the temp. to 27° causes a sudden drop of D to 2.95 (32°). On further heating it m. 67.5°, the m. p. of the α-form. The temp. of 27° seems to be the transition temp. of IV into the α-form. When the melted III is allowed to stand in a freezing mixt. for several hrs. the transformation takes place at 39°. This shift in the transition temp. is due to complete transformation into IV, since D is nearer to the value for the liquid. D of II is higher at 70.8° than that of the liquid and remains practically const. until a temp. of 47° is reached after which it rapidly begins to fall. On chilling of II the α-form is obtained and 2 distinct breaks in 4 D are found, one at 47°, the other at 30°. The α-form above 47° has the highest D. It gradually changes into the β-form. After 15 hrs. it m. at 74.5°; this indicates no transformation; after 6 days it partially m. at 74.5° and completely at 81°, and the fact that there is no further change after 1 month indicates that even then no complete transformation takes place. D of this form is much lower than in any other form, i. e., the stable form has the 5 lowest D. F. E. Brauns

Electrification by boiling and dipole moments. G. Lovera and A. Pochettino. *Nuovo cimento* **16**, 337-47 (1939).—Tests were made on a series of disubstituted derivs. of aromatic hydrocarbons of different dipole moment dissolved in inactive solvents. Solns. of compds. of zero moment remained inactive but those of compds. with a moment became active. The charge produced increases with the dipole moment of the solute. The solvents were: C_6H_6 (I), $C_6H_5CH_3$ (II), $C_6H_4(CH_3)_2$ (III), dioxane (IV). Data are given for *o*-, *m*- and *p*-$C_6H_4(NO_2)NH_2$ in I and IV, *o*-, *m*- and *p*-$C_6H_4(NO_2)OH$ in IV, *o*-, *m*- and *p*-$C_6H_4NO_2Cl$ in III, *o*-, *m*- and *p*-$C_6H_4(NO_2)_2$ in II, *m*- and *p*-$C_6H_4(NO_2)_2$ in III, biphenyl in III and IV, *o,o'*-dinitrobiphenyl in III and IV, *p,p'*-dinitrobiphenyl in III and IV, naphthalene in IV, 1,5-dinitronaphthalene in IV, 1,8-dinitronaphthalene in IV, bibenzyl in III, Et benzoate in III, crystal violet in II and IV, malachite green in II and 7 IV, diazoamidobenzene in III, amidoazobenzene in III. J. B. Austin

Aftereffects in solid dielectrics. B. Gross. *Phys. Rev.* **57**, 57-9(1939).—The discharge and residual-charge curves observed in anomalous dielectrics are discussed and 2 general relations between them are established. B. L.

The dispersion curve of hydrogen and deuterium, and of hydrogen sulfide and deuterium sulfide in the visible region. O. E. Frivold, O. Hassel and E. Hetland. *Physica* 8 **6**, 972-6(1939) (in German).—The difference in the ns ($\times 10^6$ between H_2 and D_2 varies from 1.691 at 7000 A. to 1.790 at 4200 A., and between H_2S and D_2S, it varies from 2.875 at 7000 to 3.171 at 4200 A. The difference in mol. refraction between H_2 and D_2 is 0.027 + 0.002 at all wave lengths. G. W. King

The density of gaseous chlorine. A. S. Ross and O. Maass. *Can. J. Research* **18, B**, 55-65(1940).—The d. of 9 gaseous Cl was detd. over the temp. range 15° to 75° and up to 2 atm. The values obtained are compared with those extant in the literature, and excellent agreement is found with the very precise measurements of Jaquerod and Tourpaian (*C. A.* **8**, 277) at 15° and 725 mm. pressure. There is also good agreement, over the temp. range investigated, with the measurements of Pier (*C. A.* **2**, 2183) at a pressure of one atm. The equation of state proposed by Maass and Mennie (*C. A.* **20**, 3600) fits the exptl.

results over the whole range and gives, for temps. and pressures outside the region investigated, values of the d. of gaseous Cl that afe in good agreement with the results obtained by Jaquerod and Tourpaian, and by Pier. Tables of calcd. and exptly. detd. ds. and apparent mol. wts. show the deviations of gaseous Cl from ideality. The equation of state is given in a convenient form for the calcn. of the d. of the gas in industrial applications. J. W. S.

Possibilities of breaking down gas mixtures by centrifuging. H. Hausen and R. Schlatterer. *Z. Ver. deut. Ing., Verfahrenstech.* **1939**, No. 1, 15–21; *Chimie & industrie* **42**, 303.—The rate of sepn. of gas mixts. by centrifuging is very low; similarly, the degree of enrichment produced by this method is generally low. A higher degree of sepn. can be expected only when there is a great difference in the mol. wts. of the constituents (CO_2 and H_2, C_6H_6 and air). With max. rotary speed, air can be enriched from 1% to 16% C_6H_6. A. Papineau-Couture

Temperature of gas. Its meaning and measurement. J. G. Bennett and M. Pirani. *J. Inst. Fuel* **12**, 1–4S (1939).—The meaning of gas temp. is discussed in the light of modern phys. theory. B. C. P. A.

Viscosity of gases and gaseous mixtures at high pressures. I. Golubev. *J. Phys.* (U. S. S. R.) **1**, 207–12 (1939).—See *C. A.* **33**, 6672[1]. A. D.

The Joule effect. W. B. Wiegand and J. W. Snyder. *Rubber Chem. Tech.* **13**, 49 (1940).—See *C. A.* **33**, 4097[3]. C. C. Davis

Resonance method for measuring the ratio of the specific heats of a gas, C_p/C_v. I. Arthur Lewis Clark and L. Katz. *Can. J. Research* **18, A**, 23–38 (1940).—This paper contains the description with theory of a modification of Assmann's method for detg. $\gamma = C_p/C_v$, the ratio of the sp. heats of a gas. The gas is enclosed in two chambers formed by the ends of a cylinder and a steel piston in the middle of the cylinder. This piston is caused to oscillate by an a. c. applied in coils outside the cylinder; thus the gas is subjected to alternate compression and rarefaction. The system has a natural frequency depending on the consts. of the app and the value of γ peculiar to the gas. The frequency of the a. c. is varied, the amplitude of the motion of the piston observed, and the frequency for resonance measured. From this frequency and the consts. of the app. the value of γ is detd. The method yields results of great accuracy and reproducibility. J. W. Shipley

Specific heat, enthalpy, entropy and dissociation of technical gases. E. Justi. *Feuerungstech.* **26**, 313–22 (1938).—Sp. heats calcd. for ideal gases from spectroscopic data are converted by means of various equations of state to the actual condition at a pressure of 1 atm. The difference between the mean and true sp. heats for ideal and practical conditions (1 atm.) are tabulated from 0° to 1000° for N, H, O, NO, CO, CO_2, N_2O, SO_2, H_2O, air, CH_4, C_2H_2, C_2H_4, C_2H_6 and C_6H_6. B. C. P. A.

Isothermal changes in enthalpy for some gases. Robert York and Harold C. Weber. *Ind. Eng. Chem.* **32**, 388–92 (1940).—The isothermal changes of enthalpy with pressure as evaluated from the P-V-T data for the gases ethane, propane, butane, heptane and steam were correlated by the equation $(H^* - H)_T = \Delta_1 T_c(T_r/370)^n$ where H is the molal enthalpy at the pressure, P, H^* is the molal enthalpy at zero pressure, T_c is the crit. temp. in degrees K., n is a function of the reduced temp., $T_R = T/T_c$ and Δ_1 is a function of the reduced temp. and the reduced pressure, $P_R = P/P_c$. The values of n and Δ_1 at any value of P_R and T_R are read from graphs. The calcns. were extended to CO_2, CH_4 and C_6H_6. The correlations are believed reliable between values of P_R from 0 to 8 and of T_R from 1.00 to 1.80 for hydrocarbons with crit. temps. between 300° and 600°K. L. E. Steiner

The general equation of state. Equations for ammonia and steam. J. L. Finck. *J. Franklin Inst.* **229**, 201–21 (1940); cf. *C. A.* **32**, 4862[1].—For a system in 1 or 2 phases in which only a single type of transformation occurs, the assemblage of thermodynamic states is enlarged by inclusion of the so-called metastable states. An 8-const. equation of state of the form $\eta = a + bv + cp + dpv + (e + fv + gp + hpv)\ln T$ is derived where η, v, p and T are the entropy, vol., pressure and temp., resp., and a, b, c, etc., are consts. Entropies calcd. with this equation when compared with the exptl. values show agreement to about 0.3% for satd. NH_3 and to about 2% for satd. steam. In the superheated region the agreement is not so close. L. E. Steiner

The equations of state and thermodynamics. N. Vasilesco-Karpen. *Bull. sect. sci. acad. roumaine* **21**, 199–205 (1938–39).—The relation of Maxwell-Clausius, equating the work of expansion of a liquid to gas at the pressure of the satd. vapor with that of the transition in a single phase as given by the van der Waals equation, is derived without recourse to the Carnot principle. L. E. Steiner

Some remarks concerning the theory of screening. J. Zernike. *Chem. Weekblad* **36**, 748–50 (1939).—The theory of the effect of screening (in at. arrangement) on the b. p. of a compd. is critically reviewed. Several sample calcns., based on van Laar's theorem (*C. A.* **10**, 2059) on the additivity of $\sqrt{a}$ of van der Waals equation, prove that Kossel's explanation (*C. A.* **14**, 2883) of the large fall in b. p. between the fluorides and chlorides of certain metals cannot be correct. Neither does Kossel make clear why this fall always occurs between fluorides and chlorides and never between chlorides and iodides or between hydrides and methides as his theory would predict. All elements having high-boiling fluorides and low-boiling chlorides form bases and also complex fluorides. N. Bekkedahl

The vapor pressures, heats of vaporization and melting points of N^{14} and N^{15} ammonias. Harry G. Thode *J. Am. Chem. Soc.* **62**, 581–3 (1940).—The vapor pressure difference between 70.6% $N^{15}H_3$ and ordinary NH_3 was measured for the liquids over a temp. range of 197.7–239.5°K. by means of a differential oil manometer. The vapor pressure data for the liquids can be represented by the equation: $\log_{10}(P_1/P_2) = (0.9593/T) - 0.00325$, where P_1 is the vapor pressure of ordinary NH_3 and P_2 is that of the 70.6% $N^{15}H_3$ material. The vapor pressure of ordinary NH_3 is 0.371 which is 0.174% higher than that of the $N^{15}H_3$ sample at 195°K. and 239.68°K. The $N^{15}H_3$ sample has a heat of vaporization 4.39 cal. per mol. higher than NH_3. The triple points of the 2 samples differ by 0.081°, that of $N^{15}H_3$ being higher. A. B. Garrett

Parachors of binary mixtures. Husao Isikawa and Tetuzo Atoda. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 150–61 (1939).—Parachors, $[P]$, for the systems C_6H_6–EtOH (I), PCl_3–C_6H_6 (II), and $POCl_3$–C_6H_6, measured at 25°, agree with those calcd. from values for solute and solvent by $[P] = (1 - x)[P]_1 + x[P]_2$ where x is the mol. fraction of solute. The max. deviation from the calcd. value is −1 obtained with I. $[P]$ for I and II is expressed more accurately by $[P] = a + bx$. B. C. P. A.

Determination of parachors of liquids and of dissolved crystalline substances. N. F. Komshilov. *J. Gen Chem.* (U. S. S. R.) **9**, 1539–45 (1939).—It was found possible to det. the parachors for cryst. substances in soln. The capillary method for raising the column of liquid was used in the expts. Chloroform (d_4^{20} 1.4868 and γ_4^{20} 27.29) and benzene (d_4^{20} 0.8797 and γ_4^{20} 29.07) were both found suitable, but benzene gave slightly lower values of the parachors. The exptl. values of the parachor can be detd. according to Hammick and Andrew (cf. *C. A.* **23**, 3435), but better results are obtained by using the calcn. method proposed by K. if the surface tension of the dissolved substance is detd. from the equation $\gamma_m v_m^{2/3} = \gamma_a v_a^{2/3} x + \gamma_b v_b^{2/3}(1 - x)$ where γ_a, γ_b and γ_m are the surface tensions of the solute, the solvent and the soln., resp., and v_a, v_b and v_m are the mol. vols. of the solute, the solvent and the soln., resp. The following exptl. and calcd. values, resp., of the parachors were obtained for: xylene in chloroform 290.25 and 285.10, *p*-cymene in chloroform 368.75 and 363.1, naphthalene (recrystd. before the detn.) 307.02 and 312.0, naphthalene

in the molten state at 90° 312.97 and 312.0, phenanthrene (recrystd.) 413.76 and 418.9, retene (recrystd.) 570.33 and 579.4, abietic acid (m. 163–6°, $[\alpha]_D \cong -90°$ in alc.) 725.19 and 727.9, abietic acid in the molten state 712.12 and 727.9, *d*-pimaric acid (m. 211–12°, $[\alpha]_D$ 58.8° in alc.) 712.85 and 727.9, *l*-pimaric acid (m. 148–52°, $[\alpha]_D$ 278° in alc.) 707.75 and 727.9, camphor (in benzene) 374.41 and 381.8, camphor (in chloroform) 381.4 and 381.8, fenchone 378.0 and 381.8, thyone 386.0 and 387.1, pulegone 388.41 and 392.5, camphoranil (m. 13°) 559.19 and 564.3, fenchyanil (m. 32°) 559.3 and 564.3, borneol (in chloroform) 393.73 and 387.0, camphenehydrate (in benzene) 380.79 and 387.0, camphene (in chloroform) 361.79 and 361.8. Bayer's tension did not affect the exptl. values of the parachors. Seven references and 2 tables are given. W. R. Henn 1

Reduction of specific gravity at 25°/25° to density at any temperature from 0° to 40°. R. R. Dreisbach. *Ind. Eng. Chem., Anal. Ed.* **12**, 160–1(1940).—A useful method for carrying out such computations is given. Henry J. Wing 3

Sound velocity and intermolecular forces. M. Rama Rao. *Current Sci.* **8**, 510–11(1939).—The velocity of sound v in a liquid and the molar vol. of the liquid V are connected by the equations $vV^{3.03} = R_1$, $v^{0.33}V = R$. The value of R for C_6H_6 is 951–3 (10–50°); for PhMe is 1140 1 (0–50°). Values of R and of the mol. crit. vol. V_c are tabulated for these and for C_7H_{16}, C_8H_{18}, CCl_4, PhCl, PrOAc and EtCOOEt: R/V_c varies from 3.35 to 3.71 for these compds. The velocity of sound in a liquid varies inversely as the ninth power of the intermol. distance. G. M. Petty 4

Critical opalescence of complex liquids. P. Mondain-Monval and J. Quiquerez. *Compt. rend.* **210**, 246–8 (1940); cf. *C. A.* **33**, 7636⁹.—The relation between the appearance of opalescence near the critical point of liquid mixts. and the difference (Δn) in the ns of the constituent liquids and the fact that no opalescence appears when Δn does not exceed 0.04, were confirmed and extended to cases where Δn of the pure liquids does exceed 0.04, but the Δn of the conjugate solns. does not do so. C. A. Silberrad 5

Study of the capillary properties of the free surface of a liquid with a new method for measuring the surface tension. E. Skylakakis. *Chim. Chronika* (Greece) **1938**, No. 10–12, 221–6(in Greek).—Description of a capillary phenomenon which is produced with constancy and uniformity by the impact of a drop falling on the free surface of a liquid. During the impact there appears periodically a characteristic air bubble for certain detd. heights. The period of this phenomenon is equal to the period of vibration of the drop. The method is applicable not only to water, but to other liquids such as EtOH, xylene, aniline, BzOH, AcOH, glycerol, Et_2O, olive oil and CS_2, measurements for which are tabulated. The simple app. is described. Lucien Y. Dyrenforth 6

Isotherms of helium at liquid-helium temperatures. W. H. Keesom and W. K. Walstra, *Physica* **6**, 1146 (1939)(in English).—Measurements of isotherms of He yielded the following values referred to the equation $pv = RT(1 + Bd_A + Cd_A^2 + Dd_A^4)$

	Virial coeff. of helium			
T	$B \times 10^6$	$C \times 10^9$	$D \times 10^{12}$	B cc./mol.
4.240	−3 366	− 0.260	+0.14	− 75.48
3.723	−3 918	− 1 55		− 87.8
3.105	−4.77	−10.5		−107
2.647	−5.70			−128
2.050	−8 0			−180

Amagat units are used except in the last column. Earl H. Brown 7

The flow and viscosity of liquid helium. H. E. Jones, J. O. Wilhelm and H. Grayson Smith. *Can. J. Research* **17, A**, 149–63(1939); *Univ. Toronto Studies, Phys. Ser.* No. **101**(1938–39).—Helium I has a viscosity of about 10^{-6} poises. The viscosity decreases as the temp. falls from 4.25°K. to 2.22°K. The flow of He II is the sum of a normal laminar flow plus a flow that is independent of pressure. The laminar flow corresponds to a viscosity of about 10^{-6} poises. One portion of the pressure-independent flow appears to be due to creep, and another portion depends on the intensity of illumination. The anomalous flow can be attributed to the degeneracy of the Bose-Einstein statistics. S. Bradford Stone 8

Viscosity of the systems ketones–organic acids. II. V. V. Udovenko. *J. Gen. Chem.* (U. S. S. R.) **9**, 1512–14 (1939); cf. *C. A.* **34**, 1231³.—The viscosity and d. were detd. for binary systems of MeCOEt and MeCOPr and HCO_2H and AcOH at 25°, 35° and 45°. A chem. reaction occurs between the ketones and acids studied. **III.** *Ibid.* 1564–7.—On the basis of previous data and elec. cond. studies of binary systems of ketones and acids by Kendall and Gross (*C. A.* **16**, 187), it is concluded that ds. and viscosities of the systems are functions of the chem. interaction of the components. The extent of the chem. reactions is detd. by the degree of assocn. of the acids (HCO_2H, AcOH and $PrCO_2H$) and the basicity of the ketones (Me_2CO, MeCOEt and MeCOPr), which increases with greater mol. wt. Chas. Blanc 2

Viscosity of the system boron oxide–silica and the calculation of the activation energy for some vitreous systems. A. A. Leont'eva. *Acta Physicochim. U. R. S. S.* **11**, 257–64(1939)(in English).—Data are given on the viscosity η of $Na_2B_4O_7$–B_2O_3 (*a*) and $K_2B_4O_7$–B_2O_3 (*b*) melts at 600–800°. The values of the "viscosity activation energy" B in the equation $\eta = Ae^{B/T}$ are detd. For the pure compds. $B \cong 10^{-3}$ cals./mol. and decreases slightly as the temp. increases; for (*a*) at 700°, $B = 7.2 \times 10^{-4}$ for 0% B_2O_3, 7.8 for 26%, then decreases linearly to 1.8 for 100%; for (*b*) at 670°, $B = 8.2$ for 0, 10.2 for 25, 4.0 for 60.0 and 1.8 for 100% B_2O_3. For the B_2O_3–SiO_2 system, the viscosity at 530° is a strong min. for 5% SiO_2, at 630°, two weak min. occur at 5 and 12%, whereas the 800° curve shows no min. For 12% and more SiO_2 the $\eta - 1/T$ curves are practically linear, $B \cong 2.2 \times 10^{-4}$ cals./mol. from 500 to 800°. For the 5% SiO_2 melt, B *increases* with the temp., whereas for higher SiO_2 content B decreases. L. concludes that in the 5% melt, increasing dissocn. causes interaction of the mols. leading to decrease of the coördination no. and increase of B. F. H. Rathmann 4

The velocity of fall of liquid drops in melts. M. P. Volarovich and A. A. Leont'eva. *Acta Physicochim. U. R. S. S.* **11**, 251–56(1939)(in English).—Exptl. data on the rate of fall of molten Pb drops in molten B_2O_3 at temps. of 500–700°, and of cast-iron drops in molten slag agree with values calcd. by the Hadamard-Rybczynski equation, butane 1.5 times as great as calcd. by Stokes' equation. For the rise of slag drops in metal, the Stokes' formula is, however, applicable (since η_{slag} is large relative to η_{metal}). F. H. Rathmann 5

Formation of an amorphous (vitreous) modification of water by condensation of vapor at low temperature. Leszek Staronka. *Roczniki Chem.* **19**, 201–12(1939).—A transparent coating forms in a glass tube at less than −175° (liquid N) through which a slow current of damp air is passed. The deposit becomes opaque at about −130°, and this change is assocd. with evolution of not less than 5.7 cal. per g. of the ice. The internal energy of the condensate formed at less than −170° is about 100 cal. per g. higher than that of the condensate formed at higher than −170°. The new product is considered to be a vitreous modification of H_2O. B. C. P. A. 6

X-ray and optical properties of built-up films. Seymour Bernstein. *J. Am. Chem. Soc.* **62**, 374–8(1940).—The discrepancy of about 3.6% between x-ray and optical measurements of the thickness per layer of barium-copper stearate films (Holley, *C. A.* **32**, 4074³) cannot be accounted for on the basis of x-ray refraction corrections and possible optical phase-change corrections. The results indicate that the discrepancy must be explained in terms of film structure. X-ray-measured thicknesses of Ba-Cu stearate and Ba stearate films are greater than the corresponding optical measurements; those of the Cu stearate films are less than the corresponding optically measured thicknesses. Measurements of a set of Ba-Cu 7

stearate films of varying proportions of Ba stearate and Cu stearate show that the film thickness varies greatly with film compn. and that a change in the x-ray-measured thickness is not accompanied by a change in optically measured thickness of the same magnitude. Skeletonized and unskeletonized films of the same original compn. have the same x-ray grating-space. Metal stearate films give only zero layer-line reflections while an Et stearate film showed other reflections in addn. The following film structure is suggested: The film consists of many small crystals of metal stearate embedded in a matrix of amorphous stearic acid or stearic acid crystals. These crystals of metal stearate all have the same, or nearly the same, orientation in a direction perpendicular to the slide on which the film is built but have a random arrangement in planes parallel to the foundation surface. The x-ray measurements are a measure of the grating-space of the metal stearate crystals. The optical measurements are a statistical av. of the thickness per layer. This suggested film structure is also consistent with Langmuir's interpretation (*C. A.* **32**, 6526[9]) of contact potential measurements (*C. A.* **32**, 5680[5]). A. B. Garrett

Conductivity and mobility of thin lead films. M. G. Foster. *Phys. Rev.* **57**, 42–6 (1939).—The elec. cond. of thin Pb films was measured, and the results are discussed from the standpoint of the thermodynamic stability of such films. Bernard Lewis

Structure of chromium films deposited on rock salt. Syunzi Siraj. *Proc. Phys.-Math. Soc. Japan* **21**, 800–7 (1939) (in English); cf. *C. A.* **33**, 1191[9].—The films were deposited by sublimation in a vacuum on cleavage planes of the rock salt, and their structure was studied by electron diffraction. Various orientations were obtained, depending on the temp. of the salt and the length of time it had been heated before the film was deposited. A. O. A.

Crystal growth. D. Balarev and N. Kolarov. *Ann. univ. Sofia, II. Faculté phys.-math.*, Livre 2, **35**, 143–7 (in German, 148) (1938–39); cf. *C. A.* **33**, 8475[4].—With fresh crystals, the soly. by soln. and by pptn. are the same, but with old crystals, the values may differ by as much as 1% of the gypsum content of the soln. In accordance with previous views, the thermodynamic equil. between the crystal and its surroundings depends in general on the disperse structure of the crystal, and the crystal grows or dissolves in a stepwise fashion. II. *Ibid.* 429–33 (in German, 434).—At 23° the max. difference between the soly. of gypsum crystals at the bottom and at the top may amount to approx. 2% of the $CaSO_4$ content of the soln. The direction of stirring has little or no effect on the equil. concn. of a system in which only old gypsum crystals are present; but in a system in which fresh crystals are present, the soly. changes with change in the direction of stirring, and the soly. obtained by soln. (at the bottom) may be greater than the soly. obtained by pptn. (at the top). George Ayers

Chemistry of deuterium compounds. The optically active sodium ammonium salt of 1,2-dihydroxyethane-d_2-1,2-dicarboxylic acid. H. Erlenmeyer and O. Bitterlin. *Helv. Chim. Acta* **23**, 207–9 (1940); cf. *C. A.* **33**, 6800[4].—*dl*-1,2-Dihydroxyethane-d_2-1,2-dicarboxylic acid was converted to the Na NH_4 salt and crystd. at 15° over concd. H_2SO_4 and the crystals were mechanically sepd. as in Pasteur's sepn. of racemic acid. $C_4H_2D_2O_6NaNH_4$, $[M]_D^{20} = 60.33°$; $C_4H_4O_6NaNH_4$, $[M]_D^{20} = 62.14°$; this indicates that substituting the CD group for the CH group in the Na NH_4 salt of tartaric acid affects the optical activity appreciably. A. P. Sachs

Thermal conductance of metallic contacts. R. B. Jacobs and C. Starr. *Rev. Sci. Instruments* **10**, 140–1 (1939).—The thermal cond. across optically polished contacts of Ag, Au and Cu was measured at 25° and −195° and under pressures of 0.2 to 2.5 kg. per sq. cm. The cond. of Cu varies linearly with pressure. Ag is the most suitable for contact work at low temp. B. C. P. A.

Relation between the temperature coefficients of cuprous oxide rectifiers and loading. M. I. Vitenberg. *J. Tech. Phys.* (U. S. S. R.) **9**, 1671–6 (1939); cf. *C. A.* **34**, 1893[4].—For the elec. resistance r of Cu_2O the equation $\log r = \text{const.} - \beta \log T$ holds. The value of β slowly increases when the applied potential changes from −7 to +0.1 v. and then rapidly falls when the potential rises to +0.35 v. J. J. Bikerman

The variation of the electrical conductivity of some hydrous crystals with temperature. Hikoo Saegusa and Tutomu Matumoto. *Science Repts. Tohoku Imp. Univ.*, First Ser. **28**, 235–44 (1939).—The elec. cond. of hydrates of $CuSO_4$, $CaSO_4$, $FeSO_4$, $CrNH_3(SO_4)_2$ and $K_4Fe(CN)_6$ was studied at temps. up to 450°. The cond. increases with temp. and then decreases anomalously at the dehydration temp. The water of crystn. plays an important part in elec. cond. S. Bradford Stone

Properties of some superconductors. D. Shoenberg. *Proc. Cambridge Phil. Soc.* **36**, 84–93 (1940).—The crit. field curves of pure Al, Ga, Th and Zn were measured by a magnetic induction method. The values of the transition temps., T_0, in °K. and of dH_c/dT in gausses per °K. are, resp.: Al, 1.150 ± 0.005°, 140 ± 5; Ga, 1.056 ± 0.010°, 88 ± 5; Th, 1.368 ± 0.002, 191 ± 2; Zn, 0.84 ± 0.05, 100 (± 10% approx.). A marked supercooling effect was found in Al and a smaller effect in Ga. A table is given for the degree of supercooling, $s = 1 - H_s/H_c$, of Al. H_s is the value of the magnetic field ($< H_c$) above which the specimen remains in its normal state after the temp. has been increased through T_0 and returned to its initial value at const. H. Only on reducing the field below H_s does the diamagnetic moment appear. For Al, s ranges from 0.15 to 0.63. In expts. on Ti no superconducting state was found; the failure to find the effect is discussed. Mo did not become superconducting above about 0.3°K.; U did not above 0.98°K. H. C. Thomas

X-ray investigation of the plastic deformation of crystals. III. Yu. S. Temmasov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1740–4 (1939); cf. *C. A.* **33**, 7638[8].—Cylinders of NaCl, 30 cm. long and 8 mm. wide, were extended up to 4%. This did not affect the Laue pattern of the middle of the cylinder, but the parts of the cylinder distant 1 cm. or more from the middle showed double spots, and the deformation increased from the inner to the outer layers of the cylinder. Measurements of the thickness proved that the middle part was also extended but in it a pure translation took place. No "twinning of a special kind" could be detected. J. J. Bikerman

Growth on alkali halide crystals. H. Morgenstern. *Z. Krist.* **100**, 221–27 (1938); cf. Ernst, *C. A.* **31**, 4177[8].—The development of the surface morphology of single-crystal spheres of LiF, NaCl, KCl, KBr and KI immersed in aq. soln. at 29°, and prepd. by grinding crystals obtained from the melt by Kyropoulos' method, is described. B. C. P. A.

Electron-microscope study of the beginning of precipitation of calcium carbonate from aqueous solutions. O. E. Radczewski, H. O. Muller and W. Eitel. *Zentr. Mineral., Geol.* **1940A**, 8–19; cf. *C. A.* **33**, 5615[8]. $CaCO_3$, pptd. from a satd. $Ca(HCO_3)_2$ soln. by boiling in the vacuum of a water pump, was in the form of calcite crystals 120 to 270 mμ in size. The self-evapn. of a satd. $Ca(HCO_3)_2$ soln. under the objective of the microscope gave a bubbly film of exceedingly fine amorphous $CaCO_3$ which crystd. as calcite if warmed. Aragonite and vaterite were not observed. A no. of photomicrographs at extremely high magnifications are given. M. F.

Solid solutions of hydrogen peroxide and water. P. A. Giguere and O. Maass. *Can. J. Research* **18, B**, 66–75 (1940).—An attempt was made to det. the exact compn. of the first crystals that sep. out on freezing solns. of H_2O_2 and H_2O of various concns. Special care was taken to ensure complete removal of any liquid wetting the solid phase. In all cases the crystals were found to contain both components and in proportions usually different from those in the mother-liquor. Because of the limitations of the exptl. method used, the results are only approx., but they afford ample evidence for the existence of solid solns. The possibility of H_2O_3 forming solid

solns. with H_2O is discussed from the standpoint of the crystal structure of both components. J. W. Shipley

Smits' theory of complexity and allotropy. J. L. Meijering. *Chem. Weekblad* **37**, 57–60(1940).—A review. H. S. v. Klooster

Significance of crystal habit. J. D. H. Donnay. *Am. Mineral.* **23**, 168–9(1938).—A discussion. B. C. P. A.

Identity between the Laue equation and the Bragg relation. A. Cavinato. *Z. Krist.* **100**, 439–40(1939).—See *C. A.* **34**, 1532[3]. B. C. P. A.

The microscopic forms of iron rust. Adolf Ackermann. *Kolloid-Z.* **90**, 26–8(1940); cf. *C. A.* **26**, 3466.—By means of an electron microscope the structure of rust particles, 15 min. and 15 hrs. old, was studied. Some of the younger rust particles were round and some were fiber-like, whereas the older rust particles were cryst. The young rust particles could be dyed with an aniline dye, whereas the older particles could not be dyed in this manner. The possibility of iron rust being the link between org. and inorg. matter is mentioned. S. I. A.

Orientation of the phases obtained in the course of reduction of magnetite by hydrogen. N. Buĭnov, A. Komar, M. Zhuravleva and G. Chufarov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1649–55(1939); cf. *C. A.* **33**, 5255[2].—The orientation was detd. by x-rays using the methods of Laue and of rotating crystal. Reduction of Fe_3O_4 by H_2 at 500° yields Fe the crystals of which have the orientation of the original magnetite. The same holds for FeO produced by reduction of Fe_3O_4 by H_2 at 900°. The α-Fe crystals obtained by reduction of this FeO have their (001) faces parallel to (001) of FeO and their [110] edges parallel to [100] of FeO. J. J. B.

Crystal structure of phosphorus pentachloride. Herbert M. Powell, D. Clark and A. F. Wells. *Nature* **145**, 149 (1940).—PCl_5 has a tetragonal crystal system; a_0 = 9.2 A., c_0 = 7.4 A.; d = 2.0; 4 mols. per unit cell; space group $P4_2/n$. The structure is $[PCl_4]^+ + [PCl_6]^-$. The geometry is described. G. M. Petty

The crystal structure of sodium sulfate III. Ludo K. Frevel. *J. Chem. Phys.* **8**, 290(1940).—Na_2SO_4 III has the orthorhombic space group D_{2h}^{10} *nn*; the unit cell contains $4Na_2SO_4$; at room temps. a = 5.59 ± 0.02 A., b = 8.93 ± 0.02 A., c = 6.98 ± 0.02 A. The positions of the SO_4 and Na ions and of the O atoms are given. G. M. Petty

Chlorogermanic acid and the chlorogermanates. Properties and crystal structure of cesium hexachlorogermanate. A. W. Laubengayer, O. B. Billings and A. E. Newkirk. *J. Am. Chem. Soc.* **62**, 546–8(1940).—Various attempts to prep. hexachlorogermanates from water solns. of HCl, NH_3 + HCl, NaCl, LiCl, KCl, CsCl and $CaCl_2$ failed; Cs_2GeCl_6 was prepd. from CsCl and $GeCl_4$ in a solvent of 1 vol. of alc. to 2 vols. of 12 *N* HCl. Cs_2GeCl_6 dissolves readily in water, and undergoes rapid hydrolysis; it is insol. in 12 *N* HCl and in abs. ethyl alc. but may be recrystd. from this mixed solvent; it is stable in dry air, has a d. of 3.45 ± 0.01 and forms isotropic crystals that are, for the most part, octahedral. The powder x-ray diffraction pattern for the compd. was obtained by means of Cu $K\alpha$ radiation. The data fitted a face-centered cubic lattice. Tables are included of data giving the migration of Ge during electrolysis of solns. of $GeCl_4$ in 6 *N* HCl and of the observed and calcd. intensities of the lines of the x-ray diffraction pattern. A. B. Garrett

The crystals of quartz glass. N. A. Shishakov. *Compt. rend. acad. sci. U. R. S. S.* **23**, 788–91(1939)(in English).—Charlasen (cf. *C. A.* **26**, 5800) and others because of x-ray diagrams concluded that quartz glasses, SiO_2 or many-component glasses, are amorphous. S. using the electronographical method, believes quartz glasses to be cryst. The x-ray and the electronographical methods are discussed critically. The developed theory of two-dimensional or "scaly" crystals, consisting of sheets of SiO_4 with a periodicity of 7–8 A. is in agreement with Hartleif's value 8.33 A. (cf. *C. A.* **32**, 9417[4]). F. C. N.

The mosaic blocks of crystalline quartz. N. A. Shishakov. *Compt. rend. acad. sci. U. R. S. S.* **23**, 792–3 (1939)(in English).—The paper deals with expts. and calcns. of the d. and the peptization effects of quartz powder in water. Cryst. quartz has a d. of 2.649. The lattice parameters are a = 4.89 A., c = 5.38 A.; the crystal cell vol. is: $v = (\sqrt{3}/2)a^2c$. The formula wt. being M = 60.06, the no. of mols. in the unit cell N = 3 and the mass of the hydrogen atom $m_H = 1.662 \times 10^{24}$, S. calcs. the d. ζ according to the formula: $\zeta = 2NMm_H/\sqrt{3}\,a^2c$ and obtains a value ζ = 2.688, i. e., 1.5% higher than the measured d. The cavities or pores in the quartz responsible for this effect seem to be regularly distributed cracks and lead to the conclusion of a "mosaic structure" for quartz. From sedimentation expts., the thickness of the cracks d is calcd. (The mean value λ for a particle is ≈1300 A.) $d = (v/3V)\lambda$ = 6.5 A., where v/V is the pore vol. equal to 1.5%. Several properties of quartz, such as the ability to retain many regularly distributed inclusions (e. g., amethyst) and the penetration of cations through the mineral in an elec. field, help to establish the suggested theory. Frederic C. Nachod

X-ray studies of lime. Kei-iti Akiyama. *Waseda Applied Chem. Soc. Bull.* **17**, 26–7, *Abstracts* (in English) 39(1940).—The samples of lime obtained by heating $CaCO_3$ at various temps. were analyzed by the x-ray powder method. The crystal structure of lime does not change on heating to high temps. C. L. B.

Equilibrium diagram of the copper-antimony system. IV. X-ray investigation of the copper-antimony alloys. Atomi Ōsawa and Nisaku Sibata. *Science Repts. Tohoku Imp. Univ.*, First Ser. **28**, 1–19(1939); cf. *C. A.* **33**, 6773[9].—There are 5 intermetallic compds. in the system: β, γ, δ, η and θ. Of these γ, δ and θ exist at room temp. The sp. gr. of the system was recorded. The following crystal systems and the no. of atoms to the unit cell were recorded for alloys in the annealed condition: α, Cu, face-centered cubic, 4; β, Cu_3Sb_2, body-centered tetragonal, 2*n*; γ, Cu_2Sb, simple tetragonal, 12; δ, Cu_9Sb_2, hexagonal, 2; η, $Cu_{11}Sb_2$, orthorhombic, 49; θ, $Cu_{11}Sb_4$, hexagonal, 15; ε, Sb, hexagonal, 6. J. N. L

Crystal structure of potassium sulfamate. C. J. Brown and E. G. Cox. *J. Chem. Soc.* **1940**, 1–10.—Relative intensities were measured on oscillation photographs for 309 reflections and corrected to abs. values by comparison with rock salt. Unit-cell dimensions, including 4 mols. of NH_2SO_3K, are a = 8.32, b = 8.28 and c = 5.90. The space group $D_{2h}^{11} - Pbma$ was adopted and later confirmed. Three-dimensional Patterson syntheses and the above data gave rough coördinates, which were refined by three-dimensional Bragg syntheses. The $NH_2SO_3^-$ group is tetrahedral with bond lengths S—O = 1.44 A. and S—N = 1.57 A. (both ± 0.03). The structure is ionic with 4K in 4 (*c*), z = 0.663, and 4S in 4 (*d*), x = 0.137 and z = 0.180. No hydrogen bonds are postulated, and from the above bond lengths it is concluded that both hydrogens are attached to N. W. F. Bradley

X-ray study of the phthalocyanines. IV. Direct quantitative analysis of the platinum compound. J. Monteath Robertson and Ida Woodward. *J. Chem. Soc.* **1940**, 36–48; cf. *C. A.* **31**, 3358[8].—Advantages and limitations are discussed for the direct method of analysis which is available for this (and many others) complex org. structure because of the presence of an atom so heavy that the total structure amplitudes are always +. Quant. intensity measurements were made for 302 *hol* reflections, registered photographically, scaled to abs. values by selected measurements, and corrected for absorption. The double Fourier series yielded a contour map of the b axis projection from which the positions of all atoms were detd. with an av. accuracy of ±0.05 A. Corrections were made for diffraction effects from the Pt. The mol. structure is similar to that of other members of the phthalocyanine series, but the crystal structure differs because mols. are inclined to 010 at angles of 26.5° rather than 44.2°. The space group is $C_{2h}^5 - P2_1/a$; a = 23.9, b = 3.81, c = 16.9 A. and β = 129.6°; there are 2 mols.

per unit cell. The crystal employed weighed 0.0095 mg. W. F. Bradley

The bromine-bromine distance in the dibromides of *cis* and *trans*-stilbene. James D. McCullough. *J. Am. Chem. Soc.* **62**, 480–2(1940).—The Br-Br sepns. in the mols. of the cryst. stilbene dibromides were measured by means of the radial distribution treatment of x-ray powder photographs. The sepn. was found to be 4.50 A. in the *meso* dibromide and 3.85 A. in the *dl* dibromide. In the former all groups are *trans* to one another, whereas in the latter the Br atoms are as close to one another as the van der Waals radius for Br permits. The results support the postulate of Young and Pressman (unpublished) that there is a restriction of the rotation about the single bond between the two C atoms carrying the Br; the results agree also with the elec. dipole moments found by Weissberger. A. B. Garrett

Structure of oxamide. Lore C. Misch and A. J. A. van der Wyk. *Compt. rend. soc. phys. nat. Genève* **55**, 96–8(in *Arch. sci. phys. nat.* **20**, Nov.-Dec. (1938)).—Larger crystals of $(CONH_2)_2$ than those ordinarily obtained were prepd. by boiling for long periods a suspension in H_2O or $HCONH_2$. X-ray examn. of the crystals gives *a* 5.18, *b* 3.63, *c* 5.65 A., α 66° 5′, β 81°, γ 64°; one mol. in the unit cell. The atoms are arranged chiefly in a plane parallel to *ac*. The crystals were also examd. by the method of Patterson. There is mutual attraction of NH_2 and O in the plane *ac*, which causes an increase in the C—C distance. This is estd. at 1.65 A. instead of the normal 1.53 A. B. C. P. A.

Diffraction of electrons by anthracene. A. Charlesby, G. I. Finch and H. Wilman. *Proc. Phys. Soc.* (London) **51**, 479–528(1939).—Diffraction gives results in agreement with structure as detd. by x-rays. In addn. to the normal characteristic multispot pattern, another pattern consisting of areas or islands of diffuse scattering appears superimposed, and this pattern is shown to be due to mols. which, although oriented with respect to the beam, have no definite phase relation with one another. The diffuse-area pattern is thus virtually equiv. to that which would be given by a gaseous stream of oriented mols. flowing past the electron beam. Methods for detg. the crystal orientation from a consideration of the normal electron-diffraction pattern features are developed, and it is shown that the diffuse-area pattern is due to mols. which, although in or near their normal positions and orientations, are acting as independent scattering groups. An extension of the Debye theory to mol. lattices shows that the new patterns can be explained on the supposition that the mols. vibrate thermally, as almost rigid units, about their mean positions in the lattice. B. C. P. A.

Isotherms of adsorption and surface tension. A. K. Skryabin. *Colloid J.* (U. S. S. R.) **5**, 831–42(1939).—For complicated adsorption isotherms an equation is suggested which contains 4 consts. to be deduced from expts. From this equation and the Gibbs adsorption theorem an equation for the relation between surface tension and concn. is derived. J. J. Bikerman

The adsorption of dipoles. A. R. Miller. *Proc. Cambridge Phil. Soc.* **36**, 69–78(1940).—A statistical treatment is given of the adsorption of dipoles considering electrostatic forces alone and electrostatic and van der Waals' forces jointly. It is shown that the electrostatic and van der Waals' forces give contributions of opposite sign, which almost counter-balance, to the variation of heat of adsorption with surface covered. The distribution of particles on the surface, taken into account in the treatment, has considerable effect on the variation of the heat of adsorption. H. C. Thomas

The theory of the structure and formation of a certain type of immobile adsorbed film with an application to the adsorption of oxygen on tungsten. J. K. Roberts. *Proc. Cambridge Phil. Soc.* **36**, 53–68(1940).—The structure and behavior of immobile adsorbed films on a simple quadratic lattice is discussed for the case in which each particle is so large that it is impossible for adsorption to occur on neighboring sites. The process of building up the film results in an inhomogeneous structure with gaps. 1 The sites on the surface can be divided into two groups, the gaps occurring where the regions of the surface occupied by particles adsorbed on one group and those adsorbed on another group meet. The no. of these groups is detd. and the possible configurations of particles in the boundary regions are discussed in detail. In the case of the adsorption of O_2 on W a second layer is formed over the boundary sites; the no. of second-layer sites to which the boundary sites give rise is obtained. It is shown that the exptl. 2 results are better explained on the view that the first very stable layer is mol. rather than at. H. C. Thomas

A new method for studying the adsorption of gases at very low pressures and the properties of adsorbed films of oxygen on tungsten. J. L. Morrison and J. K. Roberts. *Proc. Roy. Soc.* (London) **A173**, 1–13(1939).—A previously described method (cf. *C. A.* **30**, 1630) for detecting the adsorption of O_2 on a W filament by the change 3 produced in the accommodation coeff. of the carrying gas, argon, was so modified as to permit the calcn. of the partial pressure of O_2 in contact with the filament. Adsorption of O_2 on W at room temp. was studied at O_2 pressures ranging from 2×10^{-9} to 7.5×10^{-6} mm. of Hg. Results indicate that a film of O_2 forms on the W filament at lowest pressures and remains stable to temps. above 1100°K.; part of it appears to evaporate only at 1700°K. On top of this film O_2 is adsorbed to an extent 4 that increases with pressure, much as in the usual adsorption isotherm. **The kinetics of the formation of oxygen films on tungsten.** *Ibid.* 13–27.—The method described above was applied to the study of the kinetics of formation of oxygen films. A detailed math. analysis of the various factors influencing the rate of adsorption is included. P. H. Emmett

Mixed adsorption. A. Magnus and F. Teller. *Z. Ver. deut. Ing., Verfahrenstech.* **1939**, No. 1, 1–9; *Chimie & industrie* **42**, 303.—Mixed adsorption of different gases 5 on silica gel and activated C was studied. Silica gel adsorbs preferentially substances that contain a bridge O atom. The adsorption of pure substances by charcoal increases with the length of the C chain. As regards mixed adsorption on activated C, it has not been possible to establish a definite relation between the laws that govern it and the results of adsorption of pure substances 6 or the structure. A. Papineau-Couture

The equilibrium pressures of oxygen adsorbed on activated charcoal. Melville J. Marshall and Robert A. Findlay. *Can. J. Research* **18, B**, 35–43(1940).—Oxygen chemisorbed on activated coconut charcoal at 20° was found to exert no measurable equil. pressure. The small residual pressures obtained under exptl. conditions were due to the presence of slight impurities in the O employed. The impurities responsible for these residual pressures 7 were largely N and accompanying rare gases. The velocity of chemisorption of O decreased rapidly with increase in its concn. on the charcoal, approaching a limiting zero velocity at a concn. of 84×10^{-6} moles per g. This coincides with the concn. at which the heat of adsorption drops rapidly to the limiting value obtained for phys adsorption. After this limiting concn. was reached, adsorbed O showed true equil. with the gas phase. For small addnl. increases in concn., the equil. pressure was 8 found to increase as a linear function of the concn., with a proportionality const. of 0.276 mm. per micromole. This represents phys. adsorption as compared to chemisorption for lower O concns. J. W. Shipley

Measurements of the adsorption of helium gas on active charcoal between 4.22°K. and 1.78°K. A. van Itterbeek, W. van Dingenen and J. Borghs. *Physica* **6**, 951–60(1939)(in English).—The adsorption isotherms are 9 closely represented by the formula of William's theory. The application of the Clausius-Clapeyron equation gives the heat of adsorption, which passes through a min. of 22 cal./mol. at the λ-point, which value is close to the heat of condensation of liquid helium. Measurements of the velocity of adsorption show there is an analogy between the λ-point and crit. points. G. W. King

Chromic oxide as an adsorbent. E. H. Harbard and A. King. *J. Chem. Soc.* **1940**, 19–29.—Measurements

were made of the adsorption of CCl_4 on Cr_2O_3 prepd. by the ignition of (1) $(NH_4)_2Cr_2O_7$, (2) $Cr(OH)_3$ in a vacuum at 400°, (3) $Cr(OH)_3$ at atm. pressure, (4) a mixt. of NH_4Cl and $K_2Cr_2O_7$, (5) CrO_3, (6) Hg_2CrO_4 in a vacuum, (7) Hg_2CrO_4 at atm. pressure. The CCl_4 isotherms for the range 0–60 mm. lie in the order given for the prepns., Cr_2O_3 from $(NH_4)_2Cr_2O_7$ being the best adsorbent. The isotherms indicate the presence of unimol. adsorption and capillary condensation; the greater the amt. of unimol. adsorption, the lower is the pressure at which capillary condensation takes place. On the assumption of a capillary-condensation mechanism a relation is worked out between the surface area and the mass of vapor adsorbed at a given pressure. The adsorptions of $CHCl_3$, CH_2Cl_2 and H_2O on Cr_2O_3 are compared. A decrease in the amt. of adsorption with dipole moment is found. On successive adsorptions and desorptions of $CHCl_3$ on Cr_2O_3 the slope of the isotherm changes and the amt. of adsorption becomes progressively smaller; this is accompanied by increasingly higher pressures for capillary condensation. This appears to be due to the destruction of the smaller capillaries by the adsorption of the vapor. The fine structure of the adsorption isotherm of $CHCl_3$ on Cr_2O_3 was measured by a new type of static app. The isotherm is discontinuous both in the unimol. and the Langmuir portions of the curve. H. C. Thomas

Some recent advances in colloids. James W. McBain. *J. Chem. Education* **17**, 109–11(1940). E. H.

The acidity of Japanese acid clay. I. Various theories concerning the mechanism of the acidity of Japanese acid clay. Ken-iti Yamamoto. *Waseda Applied Chem. Soc. Bull.* **17**, 13–20, *Abstracts* (in English) 38(1940).—Japanese acid clay is generally acid to indicators such as litmus, methyl orange and phenolphthalein when brought into contact with them. A clear soln. which is filtered from a suspension of Japanese acid clay treated with distd. water contains no perceptible H ion, and the similar clear soln. obtained from suspension of Japanese acid clay which is treated with neutral salt solns. such as NaCl soln. contains distinctly free H ion. Theories which have been published in Japan for these phenomena are discussed. C. L. B.

A method for the separation of aerosols from snow and hail. O. Gabrian. *Meteorol. Z.* **55**, No. 3, 112–13(1938); *Chem. Zentr.* **1938, I**, 4158.—Petroleum at a temp. below 0° is poured over the freshly fallen snow in a glass vessel to cover it. After the snow or hail has melted, the dust particles collect at the petroleum-water interface from which they can be removed with a cotton pad and examd. M. G. Moore

Problems of equilibrium in aerosols. I. D. Gurevich and V. I. Kapustina. *Colloid J.* (U. S. S. R.) **5**, 781–95 (1939).—Aerosols were prepd. in vessels contg. various amts. of water vapor, then collected on sintered glass filters (Cottrell app. was found less satisfactory) and analyzed. Mist of vitriol oil gave aq. H_2SO_4 of the concn. corresponding to the vapor pressure p of H_2O in the vessel. Burning red or yellow P produced H_3PO_4.aq. contg. less water than solns. in equil. with the vapor pressure p. In both these cases the steady state was reached instantaneously. NH_4Cl smoke absorbs water slowly, and the concn. of the aerosol (if it contains no free HCl) tends to that in equil. with p. No indication of the effect of the particle size on the equil. vapor pressure was found. J. J. Bikerman

A new method for determining the mobilities and radii of smoke particles. L. Radushkevich. *Acta Physicochim. U. R. S. S.* **11**, 265–76(1939)(in English).—The mobilities and radii of smoke particles are detd. by means of ultramicroscopic observations on the diffusion of the aerosols through narrow slits. For polydisperse systems this method gives smaller dimensions than those obtained by the counting-weight method; for homogeneous smokes such as those of stearic acid, the results of the 2 methods show good agreement. F. H. Rathmann

Hydrous lanthanum hydroxide as an emulsifying agent. Therald Moeller. *J. Phys. Chem.* **44**, 259–63(1940); cf. *C. A.* **33**, 3658⁴.—Hydrous $La(OH)_3$, whether colloidally dispersed, flocculated from a sol by certain electrolytes, or pptd. from La salt solns., stabilizes oil-in-water emulsions. The dispersed phase may be benzene, toluene, xylene, mesitylene, kerosene, gasoline or turpentine. An emulsion of water with toluene was obtained in the presence of $K_4Fe(CN)_6$, $K_3Fe(CN)_6$, K_3AsO_4, KH_2PO_4, K_2HPO_4, K_3PO_4, $K_2Cr_2O_7$, K_2CrO_4, K_2SO_4, KF, KCl, KBr, KI, KCNS, Na_2SO_4, $Na_2S_2O_3$, $Na_2B_4O_7$, $MgSO_4$ and LiCl; whereas no emulsions were obtained with Na_2CO_3 or Na_2SO_3. No emulsion was obtained below a min. $La(OH)_3$ concn. The addn. of a gold sol to the $La(OH)_3$ had no apparent effect on the emulsifying power of the latter. No emulsions were produced when Et_2O, iso-AmOH, CCl_4 or $CHCl_3$ was used in place of the hydrocarbons. S. I. Aronovsky

Experimental investigations on laminar systems. Formation of thin layers of zinc sulfide and arsenic trisulfide on the surface of solutions of zinc and arsenic salts. S. G. Mokrushin and R. B. Ginzburg. *Colloid J.* (U. S. S. R.) **5**, 817–22(1939); cf. *C. A.* **33**, 8080³; **34**, 922².—ZnS films produced by diffusion of H_2S gas to a surface of $Zn(OAc)_2$ soln. reach a const. thickness of 30–100 A. within a few min. As_2S_3 films are thicker (up to 3000 A.) and grow for a longer time. J. J. Bikerman

The specific surface of fine powders. F. M. Lea and R. W. Nurse. *J. Soc. Chem. Ind.* **58**, 277–83(1939).—An air-permeability method for the detn. of the specific surface of fine powders was developed. The app. consists of a calibrated cylinder into which a known wt. of the powder is packed. Air or other gas is passed through this layer, and the pressure gradient is measured by flow meters. A formula for the surface per unit vol. was derived from the nature of the powder, the dimensions of the layer, and the pressure gradient. The method is satisfactory for powd. cements with specific surfaces up to 4000 sq. cm. per g.; it agrees well with sedimentation procedures. It has the advantage over permeability methods using liquids of being faster and giving reproducible results. Other methods are necessary if particle size distribution curves are required. J. H. Reedy

Effect of the granulometric composition of powders on their liquid-binding capacity. I. Ya. M. Gurevich and M. T. Berezhinskaya. *Colloid J.* (U. S. S. R.) **5**, 807–16 (1939).—Powders of ultramarine (**I**), chromic oxide (**II**), and an iron oxide contg. red lead (**III**) were sepd. in fractions having diams., d, between 20 and 10, 10 and 5, 5 and 2, and 2 and 1 μ. The sedimentation vol. of **I** and **II** in water and linseed oil increases with d, and that of **III** in H_2O and linseed oil and of **I**, **II** and **III** in xylene diminishes when d rises. The amt. of water, linseed oil or xylene necessary to produce a paste rises with d for **I** and **II** and falls for **III**. The viscosity of pastes of **I** and **II** in linseed oil increases, and that of **III** in linseed oil and of **I**, **II** and **III** in mineral oil decreases, with rising d. The systems giving unstable suspensions show a liquid-binding capacity which increases with dispersity, and other systems show an opposite behavior. **II.** *Ibid.* 823–9.—Mixts. in various proportions of large and small particles of **I**, **II** and **III** were prepd. Their capacity to bind linseed oil was additive for **III** and nonadditive for **I** and **II**. J. J. Bikerman

Influence of sorbed vapor on the static hysteresis of wetting. M. V. Chapek and N. B. Krechun. *Colloid J.* (U. S. S. R.) **5**, 763–6(1939).—The *contact angles* between minerals, water and mineral oil are for air-dry quartz 52°, calcite 60°, limonite 135°, and hornblende 45°, and for the same minerals after drying *in vacuo* 135°, 100°, 180° and 92°, resp. Obviously the low angles observed before drying are caused by adsorbed H_2O vapor. The values of the angles between graphite, water and mineral oil strongly depend on whether the dried graphite was first immersed in H_2O or in the oil. J. J. Bikerman

The nature of adhesion. N. A. De Bruyne. *Aircraft Engineer* (Supplement to *Flight*) **18**, No. 12, 51–4(1939); *Paper-Maker* **99**, TS12–15(1940).—A review of the theory according to which strong joints can never be made to polar surfaces with nonpolar adhesives or to nonpolar surfaces with polar adhesives. Subjecting *cellulosic*

materials including *wood* to excessive heat irreversibly converts them from polar to nonpolar substances. A. Papineau-Couture

Theoretical treatment of the double layer and its implications. Introductory paper. H. R. Kruyt and J. Th. G. Overbeek. *Trans. Faraday Soc.* **36**, 110–16 (1940).—Knowledge of the mechanism of the double layer is still very incomplete. There is no electrophoresis equation that takes all factors into account. The total charge on a colloid can be detd. by direct conductometric titration with NaOH; in other cases it is possible to det. directly the quantity of peptizing ions; a third method is the detn. of the max. exchange capacity of the double layer. However, the location and the distribution of the charge is a great uncertainty. The problem of colloid stability, as detd. by the protection of the double layer, is still more complicated and uncertain. Victor R. Deitz

Observations on the double-layer capacity at mercury electrodes. I. M. Barclay and J. A. V. Butler. *Trans. Faraday Soc.* **36**, 128–33(1940).—Cathode-ray oscillograms, suitably amplified, of the neg. polarization of freshly made Hg surfaces show 2 stages: (1) The more pos. region (E_H more than −0.3) in which the capacity is of the order of 50 μF/sq. cm.; (2) the more neg. region in which the capacity is about 22 μF/sq. cm. Stage (1) was observed in direct charging curves which now agree with the results of the electrocapillary calcns. and expts. with expanding Hg surfaces. The charging process took times of the order of 10^{-2} to 10^{-3} seconds; NH_4Cl and $(NH_4)_2SO_4$ were used. No appreciable differences were found in the behavior of (1) new surfaces and (2) old surfaces, at which H had been liberated and the overvoltage then allowed to decay. Hence there is no evidence that the deposition of adsorbed H occurs at any potential below that at which H_2 is continuously evolved. Victor R. Deitz

Relaxation effects in the double layer. Cataphoresis; dielectric constant. J. J. Hermans. *Trans. Faraday Soc.* **36**, 133–9(1940).—A survey, without the math. details, is given of the theory of double-layer distortion for charged spherical particles moving in an external elec. field. An attempt is made to state explicitly all assumptions that underlie the theory. The formula obtained for the cataphoretic velocity is given (cf. *C. A.* **33**, 1569[8]). The effect of the double-layer distortion on the dielec. const. of the systems considered may account for certain properties found experimentally. Victor R. Deitz

The Helmholtz. E. A. Guggenheim. *Trans. Faraday Soc.* **36**, 139–44(1940). It is suggested that a suitable unit of the moment of an elec. double layer is the "Helmholtz" defined as 1 Debye/Å^2. The p. d. across a double layer, ζ (v.) is equal to $D/12\pi \times \zeta$ (Helmholtz), where D is the dielec. const. The distinction between the moment τ of an elec. double layer and the p. d. ϕ across an elec. double layer is emphasized. Victor R. Deitz

Application of the Debye-Hückel theory to disperse systems. René Audubert. *Trans. Faraday Soc.* **36**, 144–53 (1940).—The Debye-Huckel theory, in its classical form, is applicable to dispersed systems when the ionic strength of the soln. is very small. In its limited form, nevertheless, it describes the processes by which the dispersed particle becomes charged and it permits an estn. of the surface electrochem. phenomena, as compared with selective adsorption and chem. reactions which may occur on the surface. As examples the mean radius of particles of a mastic resin, gamboge, As_2S_3 and $Fe(OH)_3$ are calcd. from the theory to be 0.8×10^{-6}, 0.67×10^{-6}, 1.43×10^{-6} and 0.65×10^{-6} cm., resp. The variation of the charge of mastic resin sols with the acidity of the liquid is calcd., as well as the surface dissocn. const. of the substance which, in certain cases, gives rise to the charge at the phase boundary. Victor R. Deitz

Electrokinetic equations and surface conductance. Survey of the diffuse double layer theory of colloidal solutions. J. J. Bikerman. *Trans. Faraday Soc.* **36**, 154–60(1940).—Theoretical. The new electrokinetic equations, which include corrections for the surface cond. of capillary and colloidal systems, give definite values for ζ, the electrokinetic potential, and account for many well-known observations such as the max. in ζ, the high dielec. const. of some sols, the charge on a colloidal particle, etc. The complete formula is $\zeta = (4\pi\eta l/DV)[(K(L-r)+2\chi)/K(L-r)]\mu$, where l is the distance between the electrodes, η the viscosity of the liquid, D the dielec. const., V the potential difference, K the specific cond. of the soln. far from the walls, χ the surface cond., r the radius of the cylindrical rod with half-spherical ends and of length L, and μ the velocity. Victor R. Deitz

Adsorption potentials. I. General theory. R. B. Dean, O. Gatty and E. K. Rideal. *Trans. Faraday Soc.* **36**, 161–6(1940).—Theoretical. Thin layers of insol. substances, permeable to at least one ionic species, cannot affect the elec. p. d. between 2 phases in equil., but affect diffusion potentials between the 2 phases only when they offer sufficient change in resistance to passage to at least one ionic species. The diffusion potential through a thin and permeable membrane is discussed in terms of the resistance to passage through it of different ions. **II. Oil-water potentials.** R. B. Dean. *Ibid* 166–73. Expts. on interfacial potentials between oils and water are described. The p. ds. were measured between a hanging drop of water and the surface of water in an overflow vessel submerged in an oil lighter than water such as ales., ethers and estes. Two egg albumin monolayers spread at these interfaces have a resistance of less than 1 ohm/cm. The spreading of a monolayer produces a temporary surge of potential which disappears with a time const. proportional to the cond. of the oil phase. The diffusion potentials of oil-water systems, though unaffected by monolayers, are considerable and were investigated as a function of the sepn. of 2 water drops in the oil with the results indicating a larger phase boundary potential and a smaller diffusion potential through the oil. For thinner layers of oil the diffusion potential gets smaller in accordance with the theory in part I and ultimately vanishes as the layer gets very thin. **III. Air-water potenials.** R. B. Dean and O. Gatty. *Ibid.* 173–9.—Ionized gas particles produced from 2 sources of Ra D plus Po are attracted to the interface between air and a monolayer on an aq. soln. Any hitting the surface condense and are discharged before returning to the gas phase. Hence no compensating double layer is built up in the gas phase to compensate for the field set up by an oriented layer of dipoles. Partial compensation of the p. d. due to the dipole field takes place in the aq. phase when the potential is measured through air ionized by a radioactive source; this also occurs when the interface is completely polarizable because the air has practically no ions in it. Victor R. Deitz

Influence of particle size on the physical behavior of colloidal systems. H. C. Hamaker. *Trans. Faraday Soc.* **36**, 186–92(1940). The manner in which the following types of forces vary with particle size is discussed (1) mutual forces between the particles; (2) force of gravity and centrifugal forces; (3) force exerted by an elec. field; (4) forces due to friction or inertia. It is suggested that moderate centrifuging will produce a concd. sol near the bottom of the vessel which by its greater d. will behave as a sep. fluid, but which is readily redispersed by shaking. At greater centrifugal speeds, this concd. sol gradually passes over into a solid deposit. If left alone after centrifuging, diffusion back into the original homogeneous state will occur, providing sintering does not occur. Victor R. Deitz

Electrical double layer and stability of emulsions. E. J. W. Verwey. *Trans. Faraday Soc.* **36**, 192–203(1940); cf. *C. A.* **34**, 1223[7].—The requirements for "stability" of an emulsion toward coagulation or sticking together of the liquid drops is investigated and the role of the emulsifier considered. The latter has the action of restoring some of the conditions existing in a double layer at the interface of a solid and a liquid. The initial ζ-potential for primary stability may be limited by 3 factors: (1) the concn. of a potential-detg. electrolyte cannot be altered in one phase only; (2) the double layer has 2 diffuse layers and the potential is divided into 2 parts on either side of

the interface; (3) development of the double layer is restricted by the dimensions of the liquid phases. Victor R. Deitz 1

Repulsive forces between charged colloid particles and the theory of slow coagulation and stability of lyophobe sols. B. V. Deryagin. *Trans. Faraday Soc.* **36**, 203–15 (1940).—Both electrostatic repulsive forces and those of a different origin, which are also observed in absence of electrolytes, are considered in deriving expressions for the force, energy and the free energy of charged spherical conductors in electrolytes and also for the velocity of slow coagulation and stability of lyophobe sols and suspensions as functions of their ζ-potential. Measurement of the forces of repulsion (pressure) exerted by thin polymol. liquid films show that the pressure decreases to zero only when the thickness is of the order of 0.2–0.3 μ. For glass and other hydrophile surfaces great deviations exist with theory based on the equation of Debye-Hückel at av. and high concns. The pressure of thin layers depends to a great extent upon the concn. of dissolved mols., among them nonelectrolytes. Victor R. Deitz 2

Stability properties in hydrophobic sols; application of the mutual energy of two particles. S. Levine and G. P. Dube. *Trans. Faraday Soc.* **36**, 215–29(1940).—Theoretical. No particular upper range of values is assigned to the particle size in stable sols. Other subjects discussed are stepwise coagulation and peptization, and coagulation at high concns. of electrolytes with corresponding high crit. ζ potential. The method of detg. ζ as a function of the particle radius, electrolyte concn. and van der Waal's energy of attraction is illustrated with known data on the AgI sol. Victor R. Deitz 3

Significance of the phenomenon of the electrical charge on the stability of hydrophobic dispersions. H. Eilers and J. Korff. *Trans. Faraday Soc.* **36**, 229–41(1940).—A criticism is made of the data on which the relation between the ζ potential and the stability of lyophobic colloidal systems is based. The proper factor which dominates the stability is the energy required to bring together 2 particles of the dispersion against the action of their elec. field. The following formula is derived from a dimensional analysis and applied to the data on the stability of oil-in-water emulsions collected by Limburg (*C. A.* **21**, 684, 1391) and Powis (*C. A.* **9**, 737; **10**, 2825). The factors, ζ, the electrokinetic potential, the concn. (c) and the valency (z) of the ions present in the water phase are contained in the formula: $A = C\zeta^2/K$, where A is the elec. repulsion energy and $K = 10^{7.864}\sqrt{\Sigma(cz)^2}$. Victor R. Deitz

Electrical double layer in relation to the stabilization of emulsions with electrolytes. D. F. Cheesman and A. King. *Trans. Faraday Soc.* **36**, 241–7(1940); cf. *C. A.* **32**, 6924[2].—Systematic search has shown that 19 electrolytes are capable of stabilizing emulsions of water in polar org. liquids or vice versa; 13 electrolytes yield no emulsion. The stabilizing effect of electrolytes is evident over a limited optimum concn. range. The sequence in order of decreasing stability imparted to an emulsion of water in amyl alc. for K salts is: CNS, I, NO_3, Br, ClO_3, SO_4; similarly for cations of different chlorides: Sr, Cu, K, Li. Globules of water-in-oil emulsions with electrolytes are positively charged; those of opposite type are negatively charged. Victor R. Deitz 8

Electrochemistry of platinum sols. IV. The particle charge of hydrogen-platinum sols. A. V. Zimin and N. A. Bakh. *Acta Physicochim. U. R. S. S.* **11**, 1–20 (1939) (in English).—Exptl. data on the cond. and its change on coagulation and the properties of various H_2-Pt sols are given in 15 figs. and tables. The sols are acidoid, the av. radius of particles is 2–2.5 $\mu\mu$, the total charge is 1.73×10^9 e. s. u. for 100 mg. per l., the charge d. 3.1×10^4 e. s. u./sq. cm.; cond. is due to the individual sol particles, the cataphoretic velocity is 3.4 μ/sec. per v./cm. at the min. in the $Ba(OH)_2$ curve and 6.7 μ in the NaOH min., 5.0 μ in pure sols independent of their concn. The values of r calcd. from ultramicroscopic counts (= 14.7 $\mu\mu$) is much too large. Complete replacement of H^+ by Na^+ takes place at pH = 8.8. F. H. Rathmann 9

Changes brought about in colloids by dialysis. B. N. Desai and P. M. Barve. *Trans. Natl. Inst. Sci. India* **2**, No. 2, 39–68(1939).—A review. Cf. *C. A.* **28**, 2244[1,3]; **31**, 1274[7], 2063[9]; **33**, 6680[3,5]. Donald C. Bond

Ultrafiltration. IV. M. Amat and J. Duclaux. *J. chim. phys.* **36**, 256–62(1939); cf. *C. A.* **33**, 3655[6].—With carborundum filters colloidal particles can be sepd. and the diam. of the particles and amt. of each size can be estd. The diams. are detd. by the grain size of the carborundum used for the filters. Suspensions of As sulfide, $Fe(OH)_3$, Au, Cu ferrocyanide, Cu cobalticyanide and Prussian blue were studied. Biol. colloids, such as gelatin, milk, gums and soaps, were found to be heterogeneous in size. L. P. Hall

pH change in gold-sol formation. C. L. Throckmartin and C. H. Sorum. *J. Phys. Chem.* **44**, 247–55(1940).—The Au sols were prepd. by the reduction, with HCHO, of a soln. of $AuCl_3$ made alk. with K_2CO_3, and a small amt. of resorcinol was added to aid in the formation of nuclei. The temp. and the concns. of the K_2CO_3, HCHO and resorcinol were varied. The changes in pH during the formation of the gold sols were measured with a glass electrode, and typical pH-time curves (consisting of 4 parts) were obtained. The exptl. results appear to verify the fact that the reduction of $KAuO_2$ by HCHO is an autocatalytic reaction. S. I. Aronovsky

Preparation of rhenium in a colloidal state and its catalytic properties. C. Zenghelis and Catherina Stathis. *Kolloid-Z.* **90**, 129–31(1940).—See *C. A.* **33**, 8081[2]. J. E. D.

Electrochemical properties of stearic acid hydrosol. I. S. Mukherjee and N. P. Datta. *J. Indian Chem. Soc.* **16**, 563–72(1939).—Reproducible pH values for stearic acid hydrosols were secured with the H electrode by weak platinization and washing with cond. water in a current of H. Titration curves obtained with $Ba(OH)_2$ and $Ca(OH)_2$ show a well-defined inflection at pH 6.5–7.0. With NaOH, there is a weak inflection at pH 9.0–9.5, resembling a weak acid-strong base curve. With NH_4OH the curve rises steeply, flattens after pH 9.0, and the particles dissolve. The total acidity calcd. from the inflection points agrees with the stoichiometric concn. of acid. The max. buffer index calcd. from the NaOH curve corresponds to more alkali than half-neutralization. The strong buffering at pH 6.5–7.0 in the $Ba(OH)_2$ curves is explained on the basis of a two-phase system with a double solid phase of the Ba or Ca salt and the solid acid. In the presence of neutral salts the titratable acidity corresponds to the stoichiometric concn. of the sol. Ultrafiltrates with and without salt mixts. show little or no total acidity. II. N. P. Datta. *Ibid.* 573–82.—The dissocn. const. of stearic acid is calcd. from soly. and cond. data of the hydrosol. The soly. of stearic acid at 35° and 50° is 1.17×10^{-5} N and 5.77×10^{-5} N, resp. K values are 1.7×10^{-6} at 35° and 2.6×10^{-6} at 50°. Addn. of $BaCl_2$ or $CaCl_2$ rapidly reduces the pH of the sol to a const. level at pH ~ 4.0; KCl causes a slower and smaller decrease near pH 5.2. The ion-product ratio for salt/acid reaches a const. level for Ba and Ca, indicating formation of solid stearates. For KCl this ratio varies continuously with the salt concn. and indicates no solid phase. The soly. of Ba and Ca stearates is 9.02×10^{-6} N and 6.15×10^{-6} N, resp., at 35°, and 2.21×10^{-5} N and 2.33×10^{-5} N, resp., at 50°. Addn. of AcONa to stearic acid sol increases the pH continuously to pH 7.0. With Ba and Ca acetates, there is a low max. followed by a much slower rise to pH 7.0 owing to the formation of AcOH, accompanied by buffer action of added salt. The pH of stearic acid hydrosol is lower at 50° than at 35°, owing to an increase of acid in soln. S. R. Korman

Electrochemical properties of colloidal silicic acid. I. Interaction with bases. B. Chatterjee. *J. Indian Chem. Soc.* **16**, 589–606(1939).—Potentiometric titration of silicic acid sols with $Ca(OH)_2$, $Ba(OH)_2$ and NaOH reveals an initial inflection in the curves at pH values ranging from 4.5 to 5.5, resp. There is no other inflection below 11.0–11.7, obtained with concd. NaOH. This order conforms to the relative insolubilities of the corre-

sponding silicates. The total acidity of the sols ranged from 3.8 to 14.5 × 10^{-5}, with SiO_2 concns. of 0.026 to 0.33 g. mols per l. The total acidity of the ultrafiltrates went from 0.75 to 1.2 × 10^{-5}. Silicic acid sols possess an intrinsic acid character independent of the presence of dissolved acids, and the acidity is attributed to no acid other than silicic acid in soln. The total acidity at the second inflection corresponds to the silica concn. The value of the ratio $Na_2O:SiO_2$ is 1 2, and the compn. corresponds to half-neutralization, or $NaHSiO_3$. The inflection points lie at pH slightly lower than those of acids in soln. As the range of SiO_2 concn. decreases, the pK values drop from 11.0 to 10.41. The max. buffer capacity varies from 0.54 to 0.035, although the corresponding theoretical value in a true soln. would be 0.20 to 0.015. The colloidal particles are deemed to act as a reservoir for generating fresh acid. II. **Interaction with neutral salts.** *Ibid.* 607-15.—Progressive addn. of $BaCl_2$ or $CaCl_2$ to silicic acid sols lowers the pH, at first rapidly and then slowly, from pH 3.8-4.0 to values between 3.2-3.4. Although Ca silicate is less sol. than Ba silicate, the lowering of pH is greater when the Ba salt is used. This is accounted for by the greater energy of elec. adsorption of Ba ions with larger displacement of H ions in the double layer assocd. with the colloidal silicic acid particles. The total acid liberated by exhaustive leaching of silicic acid sols with neutral salt solns. follows the sequence Ba > Ca > Na > Li. If the acetates are substituted for the chlorides the differences are more pronounced. The reaction is represented as a displacement of "mobile" and "bound" H ions. The relative cation mobilities and energies of adsorption det. the efficiency of total displacement. The action of univalent cations is limited almost exclusively to the displacement of "mobile" H ions in the double layer. This is demonstrated by the observation that the total acidity of the sol + salt ultrafiltrates is the same as that of the sol, whereas the pH of the sol + salt mixt. is about equal to that of the sol alone. S. R. Korman

Electrical conductivity of deformed sand. A. I. Aref'ev. *J. Tech. Phys.* (U. S. S. R.) 9, 1662-7(1939).—The resistance of sand kept between bright metal electrodes increases when it is continuously stirred. J. J. B.

The specific-volume factor in ultracentrifuge analysis. E. O. Kraemer. *J. Franklin Inst.* 229, 393-7(1940).—A brief math. treatment of the effect of combination between a macromol. material and other components of the soln. on the detn. of the mol. wt. of the macromol. by means of the ultracentrifuge. Equations for the estn. of the error due to combination or to solvation are given; it is shown, however, that solvation leads to no appreciable error in mol. wts. of proteins for the types of solns. normally used in the Upsala labs. The modification of the frictional resistance of a mol. by solvation is also discussed, and it is pointed out that from ultracentrifugal data alone it is impossible to distinguish between solvation and nonsphericity of the particle as the cause for frictional ratios greater than 1. Edward B. Sanigar

Sedimentation investigation of coarsely disperse systems. Influence of the concentration of the disperse phase on the distribution function of the particles in aqueous suspensions of barium sulfate in the presence of electrolytes. N. A. Figurovskiĭ and V. N. Rozanova. *Acta Physicochim. U. R. S. S.* 11, 361-78(1939)(in German).—The size distribution of aq. 0.05-3.0% $BaSO_4$ suspensions as a function of concn. was dtd. by means of a glass sedimentation balance. For suspensions free of all other ions, a 0.05 to 2% increase in the coarse fraction was noted in concd. suspensions, ascribed to self-coagulation. Foreign ions, such as Na^+, Cl^-, H^+, SO_4^{--}, OH^-, greatly accelerate coagulation in the more concd. suspensions. For low ratios of electrolyte to suspended phase, the effect of the former is reduced owing to its adsorption. F. H. Rathmann

Sedimentation and diffusion measurements on pectic substances. Sigurd Saverborn. *Kolloid-Z.* 90, 41-50 (1940).—An attempt was made to characterize various pectic materials by measuring the sedimentation velocity in the ultracentrifuge, as well as by diffusion and viscosity measurements. Free, extd., hydrolyzed and nitrated pectins from apples, currants and citrus fruits were used in these expts. The prepn. of the various pectins is described. The data indicate definite differences between the free pectic substances (obtained directly from the expressed juice) and those obtained by acid or neutral extn. at higher temps. Sedimentation velocity measurements showed that the free pectic materials were not uniform in mol. size. A 2-hr. hydrolysis with 0.05 *N* H_2SO_4 tended to bring these pectin mols. to a more uniform size. Nitration of the pectic substances resulted in nitropectin products similar to nitrocellulose, giving sedimentation consts. of the same order as those obtained with some nitrocelluloses in the identical solvents. S. I. A.

Elasticity of organo-gels in relation to hysteresis in sorption. Kittur Subba Rao. *Current Sci.* 9, 19-21 (1940).—The prepn. of Ca arabate is described. This material was taken through 4 cycles of sorption and desorption of water. On a weight-of-water *vs.* pressure diagram, a hysteresis occurs, which decreases and eventually disappears on the fourth cycle. The cavities in the Ca arabate have rigid walls which "trap" and retain water during desorption. With repeated cycles the gum swells and the walls of the cavities become more elastic. After sufficient use they no longer "trap" water, and the hysteresis effect disappears. Some of the cavities have necks of mol. dimensions. Similar results were obtained with rice and with the grain of *Cajanus indicus*. When the cycle is carried out with rice, with CCl_4, the hysteresis loop is permanent, as there is no swelling, and the porous gel retains its rigidity indefinitely. G. M. Petty

Structure of gelatin sols and gels. VI. Adsorption of water vapor and the electrical conductivity. S. E. Sheppard, R. C. Houck and C. Dittmar. *J. Phys Chem.* 44, 185-207(1940); cf. *C. A.* 27, 2031.—The sorption of water vapor by dry gelatin and its elec. cond. were detd. at various degrees of relative humidity. Two types of gelatin were used, i. e., ash-free, "lime-processed" calfskin gelatin (isoelec. point at pH 4.8) and ash-free "acid-processed" pigskin gelatin (isoelec. point at pH 8.2). The samples were used in the form of skins or films obtained by coating cellulose nitrate surfaces with the gelatin soln. and then stripping off the gelatin skins. The pH and concn. of the gelatin sol, the thickness of the gelatin layer, and conditions of drying the layer were varied. Little difference in adsorption was observed until the vapor pressure approached satn., when the lime-processed material showed greater adsorption. The sorption isotherms are curves of double flexure, resembling those obtained with cotton, cellulose wool, silk and other fibrous materials. The moisture regain decreases with the pH of the gelatin sol (at coating), but no min. was found at the isoelec. point. The elec. cond. increases with the moisture content, and the logarithm of the cond. is a linear function of the moisture content. The elec. cond. shows a decided min. at the isoelec. point. The results are discussed in connection with x-ray studies of the structure of gelatin. The sorption of water vapor appears to be largely conditioned by the fine structure of the xerogel, but this again is conditioned by chem. interactions of the protein mols. S. I. Aronovsky

The colloidal chemical properties of thermolyzed gelatin and the potentiometric titration of the products of its acid decomposition. M. A. Khenokh. *J. Gen. Chem.* (U. S. S. R.) 9, 1479-88(1939).—Treatment of 1% gelatin soln. in an autoclave at 120° for 20 hrs. decompd. the gelatin to high-mol. compds. (polypetides) which resemble in their reactions the initial gelatin. A decrease in viscosity of gelatin solns. was especially pronounced after thermolysis of 5 and 10% gelatin solns.; this is attributed to the destruction of the structural viscosity of gelatin. The hydrolysis of gelatin to polypeptides had no effect on the change in viscosity of the soln. The chem. solvation of gelatin increased in the thermolysis, which was accompanied by a partial destruction of the polypeptide linkage. The potentiometric titration of the products of thermolyzed (at 150°) gelatin soln. in 2% HCl or 2% H_2SO_4 disclosed

the formation of cyclic compds. In this case the potentiometric titration curves were practically the same for 1 and 3 hrs.' treatment. The hydrolysis of gelatin at 180° for 1 hr. completely destroyed the peptide linkage, whereas that at 150° even for 3 hrs. did not destroy the biuret complex. An increase in the protective action of thermolyzed gelatin soln. pointed to the preservation of colloidal properties of gelatin even after 20 hrs. of autoclaving at 120°. A. A. Podgorny 1

Solvatation of proteins in aqueous solutions of weak acids and bases. I. Interaction of casein with aqueous solutions of acetic, lactic and citric acids. V. A. Vilenskiĭ and A. Ya. Korolev. *Colloid J.* (U. S. S. R.) **5**, 843-9; *Compt. rend. acad. sci. U. R. S. S.* **24**, 52-5 (in German) (1939); cf. *C. A.* **30**, 7420⁷.—Casein sols sepd. from an acid soln. by a collodion membrane contain in the equil. state more acid than the Donnan theory requires. Presumably undissocd. acids are adsorbed by casein. The amt. expected by the theory was calcd. assuming that the activity coeffs. of H ion in casein soln. and in acid soln. were equal. J. J. Bikerman 2

Solubility of sulfur dioxide in water. W. L. Beuschlein and Louis O. Simenson. *J. Am. Chem. Soc.* **62**, 610-12 (1940).—Data are given for densities of SO_2 solns. and partial vapor pressure of the system SO_2-H_2O over the temp. range 20-110° and total pressure range of 10 to 150 cm. of Hg for concns. of 0.51, 1.09, 4.36 and 7.45 g. of SO_2 in 100 g. of H_2O. A. B. Garrett 3

Solubility of alkali sulfates and carbonates in ammonia-water mixtures. A. Guyer, A. Bieler and E. v. Orelli. *Helv. Chim. Acta* **23**, 28-33 (1940).—The solubilities at −30, −10, 0 and about 23° in aq. solns. varying from 0 to 100% NH_3 were detd. for Na, K and NH_4 sulfates and carbonates. The curves are given. W. E. Vaughan 4

Mutual solubility of aluminum, sodium, potassium and iron nitrates in water in the presence of nitric acid. III. A. I. Zaslavskiĭ and Ya. A. Ravdin. *J. Gen. Chem.* (U. S. S. R.) **9**, 1473-8 (1939); cf. *C. A.* **30**, 1644⁴.—The soly. isotherms of the system $Al(NO_3)_3$-$Fe(NO_3)_3$-H_2O at 0°, 20° and 40° were studied. The true equil. between the solid and liquid phases was effected by soln. of the salts at higher temps. and crystn., with vigorous stirring, at the given temps. The compn. of the solid phase was studied by Schreinemakers' method and by detn. of ds., *n* and m ps. of the mixed crystals. The tabulated and plotted results show the formation of continuous series of mixed crystals of $Al(NO_3)_3.9H_2O$ and $Fe(NO_3)_3.9H_2O$ with unlimited soly. at all the temps. investigated. Chas. Blanc 5

The vapor pressures of saturated salt solutions. O. W. Rees and G. W. Land. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 119 (1939).—Vapor pressures were detd. for the following satd. solns., with a Rayleigh or "rocker arm" type of manometer: $KClO_3$, K_2SO_4, $BaCl_2$, KCl, NaCl, NH_4NO_3, $Ca(NO_3)_2$, $KC_2H_3O_2$ and LiCl. The values obtained agree well with the values usually accepted in the literature. J. H. Reedy 6

Generalized theory of diffusion. I, II. E. J. Hellund. *Phys. Rev.* **57**, 319-28, 328-33 (1940).—Math. G. M. E. 7

The conductance of some salts in chlorobenzene at 25°. Robert L. McIntosh, Darwin J. Mead and Raymond M. Fuoss. *J. Am. Chem. Soc.* **62**, 506-8 (1940).—The conductances of tributylammonium picrate, tetrabutylammonium picrate and tetrabutylammonium bromide were detd. in chlorobenzene at 25°. From these data the values of the ion size, *a*, and the consts. for the ion pair and triple ion equilibria are evaluated. Specific interaction can appear between solvent and solute even in strong electrolytes, and forces other than coulomb interaction between ions must be considered in a general quant. description of electrolytic behavior. A. B. G. 8

The specific electric conductivity of the binary and the ternary systems containing the chlorides and the sulfates of sodium and magnesium. V. I. Nikolaev and I. S. Katyk. *J. Gen. Chem.* (U. S. S. R.) **9**, 1611-18 (1939).—The sp. elec. conductivities at 25° in the regions of unsatd. aq. solns. (up to the satn. state) were investigated in the binary and ternary systems contg. Na and Mg chlorides and sulfates. The results of the investigations are compared with the data of the heat capacities of the same systems at 25° as given in the literature. The max. on the isotherms of the sp. elec. conductivities in the binary systems correspond in their compns. to the transition points or to the min. of the heat capacities. In the ternary systems NaCl + $MgCl_2$ + H_2O (25°) and $MgSO_4$ + $MgCl_2$ + H_2O (25°) "special points" were observed which divided the isotherms-isoconcentrates of the sp. elec. conductivities (and heat capacities) into two distinct branches. Transition points were observed on the polytherms of the elec. conductivities of the isoconcentrates of Na_2SO_4. Theoretical considerations and exptl. data showed an analogy between the structure and the properties of the solid and the liquid (aq.) solns. The "liquid hydrates" correspond to the solid chem. compds. The observed "special points" correspond to the transformation of one type of the water-salt complexes into complexes of another kind. They are points of coexistence of different types of complexes. Ten diagrams, 3 tables and 3 references are given. W. R. Henn 9

Determination of the specific electric conductivities of very dilute solutions of some electrolytes. B. P. Tatarinov and M. V. Levitskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 1619-21 (1939).—The little known sp. elec. conductivities of the solns. of Na_2CO_3, NaCl, $CaCl_2$, Na_2SO_4 and $MgSO_4$ in concns. of 0.001-0.000067 *N* were detd. The results are given in 6 curves of diln. *vs.* sp. elec. cond. A Wheatstone bridge was used for the measurements. All measurements were made in a thermostat at 25°. The solns. of the salts investigated were not freed from the aggressive gases to avoid any complications arising during the expts. A correction was made for the elec. cond. of water by additional detns. of the elec. cond. of the bidistillate and of a part of the investigated solns. The accuracy of the measurements was checked by available calcd. values, which gave the same results. W. R. Henn 10

The determination of mobilities and dissociation constants by means of conductivity titrations. Joan P. Philpot, Edwin C. Rhodes and Cecil W. Davies. *J. Chem. Soc.* **1940**, 84-7.—The methods are not suited to work of highest accuracy but are rapid and useful where only small quantities of material are available. Titrations of propylamine, of ethylenediamine, of *p*-chloroaniline-HCl and of *m*-chloroaniline-HCl are reported and discussed. The general effect of a substituent amino group is to increase, and not to decrease, the acidic properties of a mol., although at the same time it provides a new center of basic properties. H. C. Thomas 11

The extent of dissociation of salts in water. IX. Calcium and barium salts of dicarboxylic acids. Norman E. Topp and Cecil W. Davies. *J. Chem. Soc.* **1940**, 87-93; cf. *C. A.* **33**, 3236⁷.—By means of cond. titrations the dissocn. consts. of the Ca and Ba salts of succinic (K = 0.010 and 0.027, resp.), adipic (0.0064, 0.014), fumaric (0.010, 0.026), maleic (0.0037, 0.0055), malic (0.0022, 0.0064), tartaric (0.0016, 0.0029), *o*-phthalic (0.0037, 0.0047), and isophthalic (0.010, 0.028) acids were detd. A wide diversity of behavior is shown. The Ba salts are all stronger than the corresponding Ca salts. If the salts of the above cations are arranged in order of decreasing dissocn. const. the disposition of the anions is not the same in the 2 series; this shows that the order is not governed solely by the diam. of the anion. The ratio of the mobility of the intermediate ion HA^- to that of the bivalent ion A^{--} is high for all those acids with weak Ca and Ba salts. H. C. Thomas 12

Degeneracy and dissociation constants. H. O. Jenkins. *Nature* **145**, 149-50 (1940).—Linear relations exist between the complexity of degeneracy, defined in terms of the no. of possible resonating structures, and the dissocn. consts. of series of related acids and bases. G. M. Petty 13

The anomalous strength of butyric acid. H. O. Jenkins and J. F. J. Dippy. *J. Am. Chem. Soc.* **62**, 483-4 (1940).—The abnormality in the magnitude of the dissocn. const. of butyric acid as compared with the dissocn. consts. of formic, acetic and propionic acids is attributed to a

restricting potential in the mol.; this agrees with conclusions reached in studies of infrared absorption, Raman spectra, heat capacity and dipole moment. This interpretation has resulted from the discovery of a linear relation between the logarithms of the dissocn. consts. of formic, acetic and propionic acids and the inverse of the sixth power or γ, the distance sepg. the carbon of the carboxyl and the terminal group of the acid. This relation predicts a limiting value for the dissocn. consts. of the higher acids. The slope of the line agrees well with a theoretical expression. A. B. Garrett

The temperature dependence of the dissociation constant of deuterioacetic acid. Frank Brescia, Victor K. La Mer and Frederick C. Nachod. *J. Am. Chem. Soc.* **62**, 614–17(1940).—The equiv. conds. of NaCl, NaOAc, HCl and HOAc were measured at 14.36°, 25°, 35° and 44.86° in a solvent whose deuterium fraction was 0.925. From these data the dissocn. const. of DOAc at $F_D = 1$ is calcd. at corresponding temps. The dissocn. const. of DOAc follows the Harned-Embree equation (cf. *C. A.* **28**, 6611[6]) and passes through a max at 31°; that of HOAc passes through a max. at 22°. The ratio K_H/K_D decreases with increasing temp. The differences in the heats, free energies and entropies of ionization of the deutero and proto acids were calcd. The value of ΔC_p for the exchange process $HOAc(H_2O) + D^+(D_2O) + OAc^-(D_2O) = DOAc(D_2O) + H^+(H_2O) + OAc^-(H_2O)$ is sensibly zero; the value of ΔS is sensibly const. and equal to -1.3 cal. deg.$^{-1}$ mol^{-1}. The almost zero value of ΔC_p in these exchange processes results from the fact that ions of the same valence type and almost identical chem. properties are involved in these equilibria. A. B. Garrett

Electrostatic effects on ionization constants. Victor K. LaMer and Frank Brescia. *J. Am. Chem. Soc.* **62**, 617–20 (1940).—Data on the dissocn. consts. of deuterioacetic acid (cf. preceding abstr.), together with data by Harned (cf. *C. A.* **31**, 6536[1]) on protoacetic acid serve as good tests for the equation $\Delta H_I = \Delta H_I + c(1/D_T)[1 + T(\partial \ln D/\partial T)]$, derived by Baughan (cf. *C. A.* **33**, 9096[2]) for the heat of ionization, ΔH_I, of a weak acid of the elec. charge type $HA + H_2O = H_3O^+ + A^-$ as a function of the temp., T. The data indicate that this equation represents the value of ΔH with high precision when $\Delta H_I = 2260$ cal. and $c = 4.410 \times 10^5$ for deuterioacetic acid. The values of protoacetic acid are 2030 cal. and 4.714×10^5, corresponding to γ values of 0.75 and 0.70 A., resp. The difference in the heats of ionization of deuterio- and protoacetic acids appears to be a function only of the characteristic temp., θ, at which the max. value of the dissocn. consts. occurs. The empirical const. $p = 4.5 \times 10^{-5}$ in the Harned-Embree equation (cf. *C. A.* **28**, 6611[6]) is shown on theoretical grounds to be equal to $p = (\epsilon^2/2.3RT D^3)(\partial D/\partial T)^2(1/2\theta)$. A. B. Garrett

The electrolytic dissociation of dicarboxylic acids in water and in aqueous solutions of alkali chlorides. Birger Adell. *Z. physik. Chem.* **A185**, 161–206(1939).—The following acids were studied electrometrically in solns. of NaCl and KCl of ionic strengths (μ) up to 3.0: $COOH(CH_2)_nCOOH$ ($n = 1, 2 \ldots 7$), COOHCH=CHCOOH (*cis* and *trans*), $COOH(CH_2)_nS(CH_2)_nCOOH$ ($n = 1, 2, 3$), $COOHCH_2S(CH_2)_nSCH_2COOH$ ($n = 0, 1, 2 \ldots 5$). The primary and secondary dissocn. consts. (expressed in the logarithmic form as pK'_c and pK''_c) were evaluated and by extrapolation to $\mu = 0$, the corresponding thermodynamic dissocn. consts. (pK'_a, pK''_a) were found. For the normal paraffin dicarboxylic acids and for the polymethylenebisthioglycolic acids the equation of Greenstein (*C. A.* **30**, 5859[2]) gives the variation of pK'_a with the distance between the carboxyl groups. $pK''_a - pK'_a$ expresses (Ingold, *C. A.* **25**, 5824) the distance, r_I, between the charges on the bivalent anion; r_I decreases with increase in the no. of S atoms and this decrease is greater the larger the no. of terms between the carboxyl groups. For the normal paraffin acids the values of r_I are compatible with the assumption of a rigid zigzag chain model of the mol.; this is not true, however, for the S-contg. acids. If the Cl-ion concn. is increased, the quantity $p\phi' = pK'_a - pK'_c$ goes through a max. at $\mu = 0.5$ and then decreases; for $p\phi''$ the max. is at $\mu = 1.0$. For a given medium $p\phi''$ is always appreciably larger than $p\phi'$; both are larger in NaCl soln. than in a KCl soln. of the same value of μ. Differences in the values of $p\phi'$ and of $p\phi''$ for different solns. are described and correlated with differences in the structures of the acids. Calcns. of the activity function pf_A/f_{H_2A} in NaCl solns. by the method of Scatchard and Kirkwood (*C. A.* **26**, 3716) give values in good agreement with expt. For KCl solns. the agreement is poor; the NaCl and KCl values differ by a const. amt. which is independent of the nature of the acid. T. H. Dunkelberger

Probable solvation of aniline hydrochloride, aniline hydriodide and α-naphthylamine hydriodide in aniline solution—simple mathematical treatment. Herbert H. Hodgson and Ewart Marsden. *J. Soc. Chem. Ind.* **59**, 23–4(1940).—Equations are offered expressing the relation between the components of soln. where an aniline soln. of aniline-HCl, aniline-HI or α-naphthylamine-HI is used. They are based on the assumption that only part of the solute is ionizable and the remainder forms a solvated complex with the aniline and that the ionizable part obeys Kohlrausch's law. From data calcd. for aniline and α-naphthylamine-HI it is deduced that only about 10% of the α-naphthylamine-HI does not form a solvated complex. Ionization is about 1% at a concn. of 300×10^{-4} g. mols. and 1.8% at a concn. of 100.8×10^{-4} g. mols. R. F. Deese

Activity coefficient of strong electrolytes in concentrated solutions. II. S. Abe. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 260–74(1939); cf. *C. A.* **32**, 3239[9].—Activity coeffs. calcd. according to a previously published theory are compared with exptl. results in the cases of NaCl, HCl, $ZnSO_4$ and $CaCl_2$. B. C. P. A.

Thermodynamics of concentrated aqueous solutions of sodium hydroxide. Gösta Åkerlof and Gerson Kegeles. *J. Am. Chem. Soc.* **62**, 620–40(1940).—The thermodynamic data were obtained from e. m. f. measurements of the cell: Pt, H_2|NaOH (m_1)|Na_xHg|NaOH (m_2)H_2, Pt over a temp. range 0 to 70° and concn. range 0.1 to 17 molal. Tables are given of corrected e. m. f. data least squared with respect to temp., water-transfer potentials, consts. for the calcns. of activity coeffs. of NaOH, calcd. values for the activity coeffs. of NaOH, calcd. values for the activity and the vapor pressure of the solvent in aq. solns. of NaOH, relative partial molal free energy, relative partial molal heat content, relative partial molal entropy, and relative partial molal heat capacity for both solute and solvent in aq. solns. of NaOH, total heat capacity, sp. heat, and total relative heat content of aq. solns. of NaOH at 20°, and the differential heat of vaporization of the solvent from aq. solns. of NaOH. The activity coeff. of the hydroxide for the concn. range 0.1 to 12 molal was found to be expressed adequately by the equation $\log \gamma = \frac{-u\sqrt{m}}{(1+\sqrt{2m})} + Bm + Cm^2 + Dm^3 + Em^4$ where u is the universal const. of the limiting law, m the molality of the hydroxide, B, C, D and E are empirical consts. varying according to second-order equations with the temp. At higher concns., a second-order equation was used for the calcn. of $\log \gamma$. The effect of pressure upon the thermodynamic properties of NaOH is discussed. A. B. Garrett

Definitions of the conceptions of "acid" and "base." A. I. Shatenshtein. *J. Gen. Chem.* (U. S. S. R.) **9**, 1603–10(1939); cf. *C. A.* **33**, 7664[3].—A discussion based on the literature. Forty references. Chas. Blanc

The G. N. Lewis theory of acids and bases. W. F. Luder. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 111–18(1940).—Lewis' theory relates acids and bases to each other in a more logical and much more fundamental way than have other theories and provides a completely general and exact definition, which attributes the distinctive properties of acids and bases to the mols. themselves, independently of the solvent. The H ion-OH ion-water theory, the Brönsted-Lowry theory and the Franklin-Germann theory are merely limited aspects of Lewis'

theory. The general adoption of Lewis' theory should lead to a correlation of a large no. of hitherto unrelated chem. phenomena. Leopold Scheflan

Measurement of pH by means of the glass electrode and the hydrolysis of copper sulfate. H. Hagisawa. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 275–84(1939).—A standard buffer soln. and a given soln. are placed resp. in the inner and outer parts of the glass bulb, and then reversed; thus the asymmetric potential of the glass electrode is eliminated. The relation between pH and diln. (V) of the $CuSO_4$ is given by pH = 3.5200 + 0.6717 log V. B. C. P. A.

A pH experiment for the first course in chemistry. G. W. Thiessen. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 131–2(1939).—Simple salts (cations = Na^+, K^+; anions = SO_4^{--}, HSO_4^-, SO_3^{--}, HSO_3^-, PO_4^{---}, HPO_4^{--}, $H_2PO_4^-$, CO_3^{--} and HCO_3^-) were analyzed as follows: The cations were identified by flame tests, hydrates by ignition tests and the anions by the usual reactions with $BaCl_2$, $CdCl_2$, $AgNO_3$ and acidified $KMnO_4$. Acid salts were distinguished from normal salts by pH measurements. Calcns. of pH, ionization consts. and hydrolytic consts. were found too difficult for first-year students, and a table of pH values of molar solns. was used to distinguish between primary, secondary and tertiary anions. J. H. Reedy

The pH of sodium dichromate solutions. H. J. Kaufmann, W. B. Lauder and R. K. Kepner. *Ind. Eng. Chem.* **32**, 423–6(1940).—The pH of $Na_2Cr_2O_7$ solns. varied widely as the solns. were dild. from about 4.5 0.05 mol. per l. The curves so obtained were but little affected by the distd. H_2O used, but were affected more by the container in which the solns. were prepd. and tested. Small temp. changes had a negligible effect. Concg., rather than dilg., the solns. had no effect in the weaker ranges, but gave more acidic values in the stronger. Additns. of Na_2SO_4 and NaCl, normal impurities of $Na_2Cr_2O_7$, had but little effect on the pH of the solns. E. M. Symmes

Definition of oxidation and reduction phenomena. H. G. Bos. *Chem. Weekblad* **37**, 567(1940); cf. *C. A.* **34**, 2954. H. S. v. Klooster

Passivity of iron and steel in nitric acid solution. XXVI. Y. Yamamoto. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 162–70(1939); cf. *C. A.* **33**, 9098[2].—The extent of attack of Fe and steel in the passive state by HNO_3 increases with concn., being very rapid when the concn. of HNO_3 is greater than 94% owing to the low concn. of H_2O failing to render Fe completely passive. B. C. P. A.

The gas equilibria $C_2 \rightleftarrows 2C$, $S_2 \rightleftarrows 2S$, $Se_2 \rightleftarrows 2Se$ and $Te_2 \rightleftarrows 2Te$. H. Zeise. *Z. Elektrochem.* **46**, 38–41(1940).—For the gas equil. $C_2 \rightleftarrows 2C$ and $S_2 \rightleftarrows 2S$, the equil. consts. previously calcd. between 2000° and 6000°K. and between 298.1° and 3000°K. were corrected on the basis of new values for cleavage energy and in the 2nd case upon a new value for nuclear distance. The new figures show considerable deviation from the earlier results. The equil. $Se_2 \rightleftarrows 2Se$ and $Te_2 \rightleftarrows 2Te$ were calcd. on the basis of thermodynamic-statistical data in the temp. range from 1000° to 2500°K. The results agree approx. with older measurements if the basic state of the mols. Se_2 and Te_2 is assumed to be of the type $^3\Sigma$. H. Stoertz

Equilibrium in hydrofluoric acid solutions. W. A. Roth. *Ann.* **542**, 35–43(1939). The cond. and the H-ion concn. (indicator method) were measured at several temps. and in a wide range of concns. and also the heats of neutralization. Under the assumption that only H^+, F^-, HF_2^- and HF are present in the soln., the equil. const. $[H^+][F^-]/[HF]$ is 0.00032 and that of $[F^-][HF]/[HF_2^-]$ is 0.0335 at 20°. The heat effect of the 1st reaction is about 3.05 kg.-cal., of the 2nd is 5.07 kg.-cal. The strong hydration of the F^- ions is the cause of the relatively large heat evolution in the dissocn. of HF and HF_2^-. C. J. W.

X-ray study of products obtained during reduction of titanium dioxide. E. Belyakova, A. Komar and V. Mikhailov. *Metallurg* **14**, No. 4-5, 23–5(1939).—H reduction of TiO_2 at 1200–1500° yields primarily Ti_3O_5. At 1500° some TiO may be present. Reduction with charcoal at 1100–1500° produces a solid soln. of TiC and TiO varying from 33 to 60% TiC. H. W. Rathmann

Active oxides and reactions of solid substances. CXVII. The transition of anatase into rutile and the effect of gaseous hydrogen chloride on this transition. Gustav F. Hüttig and Kurt Kosterhon. *Kolloid-Z.* **89**, 202–8(1939); cf. *C. A.* **34**, 1225[2].—Various portions of a gel of $TiO_2.xH_2O$ (prepd. by hydrolysis of $TiCl_4$) were heated to different temps. between 750° and 1000°. On shaking with H_2SO_4 a part of each of these prepns. goes into soln.; the quantity dissolved is approx. proportional to the wt. of the portion subjected to the soly. test. All prepns. were examd. with regard to their loss on ignition, x-ray picture, soly., hygroscopicity, etc. Some of the results obtained can be attributed to the rearrangement of the surface mols. (max. at a preliminary heating to about 820°), whereas others can be considered as a consequence of a general rearrangement of the anatase lattice into that of rutile (the latter phenomenon was observed on prepns. that were heated preliminarily to 850–920°). A series of prepns. was made by heating of the TiO_2 gel in a dry stream of gaseous HCl. The soly. of prepns. heated preliminarily in HCl, at about 820–950°, is essentially greater than that of prepns. preheated in air. These differences reach a high max. in prepns. heated preliminarily to about 850°. Since an increased soly. must correspond to an intensified "loosening" (at least of the surface), the presence of gaseous HCl must promote the formation of loosened (activated) conditions. Edward A. Ackermann

The fluorination of thionyl chloride. Harold S. Booth and Francis C. Mericola. *J. Am. Chem. Soc.* **62**, 640–2(1940).—The fluorination of $SOCl_2$ with SbF_3 in the presence of $SbCl_5$ yields SOF_2 and SOClF. The reactions of these compds. with water, metals, sulfides and chlorine are discussed. Vapor pressures of SOF_2 and SOClF are tabulated, and crit. data for SOF_2 are given. The following physical consts. are given for $SOCl_2$, SOClF and SOF_2, resp.: b. p. 75.7°, 12.2° and −43.8°; f. p. −99.5° to −104.5°, —, −129.5°; m. p. —, −139.5°, —; liquid d. 1.675, 1.580, —; heat of vaporization (cal.) 7682, 5937 and 5202; Trouton's const. 21.4, 20.7 and 22.7. A. B. Garrett

The mechanism of oxidation of carbon. V. Sihvonen. *Ann. Acad. Sci. Fennicae* **A51**, No. 4, 40 pp. (1938)(in German); cf. *C. A.* **32**, 8895[3].—A review of the work of S. and coworkers since 1930 on (1) the mechanism of the electrolytic oxidation of C at room temp., (2) action of pressure, temp. and porosity on the combustion of carbon and (3) reaction order and temp. increment of various processes for C oxidation in O, CO_2 and steam. Thirty-two references. George Ayers

Velocity of solution of comminuted substances. X. Solution of tartaric acid and sugar in water. Wawrzyniec Jacek. *Roczniki Chem.* **19**, 243–8(1939).—The velocity of solution of tartaric acid and sucrose in H_2O at 17.5–21° was detd. B. C. P. A.

The heterogeneous ortho-para conversion on paramagnetic crystals. L. Farkas and L. Sandler. *J. Chem. Phys.* **8**, 248–51(1940).—The rate of conversion of para-H and ortho-D was measured on paramagnetic crystals: $CuSO_4$, $NiCl_2$ and Nd oxalate. In the last case the conversion rate has a max. at 0°. Below 0° the desorption rate of the H and the D is rate-determining. Hence, the ratio of the rates for H and D is near unity. The rate of desorption increases with increasing temp. and at higher temps. the rate of conversion on the surface becomes the slow process. The ratio of the rates for H and D approaches 1 in this region. The heat of adsorption of H on Nd oxalate is about 2.4 kg.-cal./mol. G. M. Petty

Surface conditions of silver halides and rate of reaction. I. Rate of reduction of precipitated silver chloride. T. H. James. *J. Am. Chem. Soc.* **62**, 536–40(1940).—The reduction of pptd. AgCl by N_2H_5OH was studied with particular reference to the effects of aging of the ppt., dye adsorption, gelatin adsorption and Cl^- ion concn. upon the initial reaction rate. Gelatin markedly inhibits the reaction and gives a min. rate. The reaction rate closely parallels the change in surface with aging. The reaction

is strongly inhibited by adsorption of 3,3'-diethyl-9-methylthiocarbocyanine to the AgCl; the reaction rate is approx. proportional to the free surface when the ppt. is only partly covered with dye. The probable mechanism of the reaction involves the reduction of the unprotected Ag^+ ions of the solid rather than the Ag^+ ions in soln. An excess of Cl^- ion affects the reaction rate in such a manner that it indicates that further adsorption, after the AgCl surface is largely covered with Cl^- ions, follows the Langmuir isotherm. A. B. Garrett

Stabilization velocity of glassy selenium. Husao Isikawa and Hatiro Sato. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 143-9(1939).—The stabilization velocity of glassy Se, measured by a differential gas dilatometer, is very low at 60° and increases with temp., 60% transformation into metallic Se occurring in 33 hrs. at 75°. B. C. P. A.

The extrathermal action of ultra-high-frequency electric fields. II. The effect of ultra-high-frequency fields on the polymerization of chloroprene. E. I. Yakubovich and E. I. Evdokimova. *Arch. sci. biol.* (U. S. S. R.) **55**, No. 3, 93-100(in English, 100)(1939); cf. *C. A.* **33**, 6128².—A higher rate of polymerization of chloroprene occurs under the influence of ultra-high-frequency elec. fields than under equiv. heating periods on a water bath. An x-ray analysis indicated that only the degree of polymerization is affected. The structure and particle size are not changed. The evidence is used to show the presence of an extrathermal component in the ultra-high-frequency field. S. A. Katjala

The kinetics of the reaction of amalgamated aluminum with water vapor and oxygen. M. A. Blumental. *Atti X° congr. intern. chim.* **2**, 118-32(1938).—The equation $2Al(Hg)_x + 3/2O_2 + 3H_2O = 2Al(OH)_3 + 2xHg$ represents a diffusion reaction, the Al_2O_3 formed interrupting the reaction. In the absence of O_2 the amalgamated Al reacts with H_2O vapor thus: $2Al(Hg)_x + 6H_2O = 2Al(OH)_3 + 3H_2 + 2xHg$, the reaction velocity being const. in time and proportionate to the nth power of the H_2O vapor pressure: $J = kp^n$, $2>n>1$. The temp. coeff. is neg., the adsorption decreasing with temp. The amt. of adsorption heat is indicated by Arrhenius' equation. The results thus computed agree with those computed on the basis of the kinetic gas theory. A. H. Krappe

Kinetics of the slow oxidation of carbon monoxide. A. V. Korneeva and M. V. Polyakov. *Acta Physicochim. U. R. S. S.* **11**, 427-42(1939).—Data on the kinetics of the $CO + O_2$ reaction on a Pt wire at 450-800° and at pressures of 30 mm. (below the ignition limit) are summarized. The kinetic equation $W = Ae^{\phi t}$ is applicable; the values of ϕ obtained from the linear relation $\log \Delta p - t$ show a max. value for a 5-mm. Pt wire, 1.6 at 800°, 1.25 at 700°, 0.57 at 450°. The reaction shows a limit at all temps. and is a homogeneous-heterogeneous reaction proceeding by a chain mechanism. F. H. Rathmann

Kinetics of the slow oxidation of ethylene. M. V. Polyakov and F. M. Vaĭnshtein. *Acta Physicochim. U. R. S. S.* **11**, 415-26(1939)(in English).—Exptl. data are given in 20 plotted curves for the reaction $C_2H_4 + 3O_2$ on Pt wires at 700-800°, 100 300 mm. pressure, in glass and quartz vessels of 20 30 mm. diam. The reaction reaches a limit at about 30% of gases reacted, the limit being lower the shorter the Pt wire used. The Pt wire becomes more active with use. The results show that the reaction is a case of heterogeneous-homogeneous catalysis, both proceeding by a chain mechanism. F. H. Rathmann

Kinetics of oxidation of methane. I. Intermediate products. Wilhelm Staronka and Lucjan Czerski. *Roczniki Chem.* **19**, 259-76(1939).—2.2:1 and 1:1 CH_4-O_2 mixts. were heated at 400-83°. The yield of CH_2O is max. (0.5-0.8 ml. per 100 ml. of gas mixt.) after 0.5-1 min., varying little thereafter. That of MeOH is max. (0.7-1.4 ml.) after 0.8-1.8 min., thereafter falling more or less abruptly. The highest yields of MeOH are obtained by low-temp. oxidation of CH_4-rich mixts. CH_2O is not initially produced by oxidation of MeOH. The results support the view that oxidation of CH_4 in absence of contact substances is a chain reaction, preponderatingly homogeneous, although stoichiometrically heterogeneous. B. C. P. A.

Kinetics of the decomposition of benzoyl peroxide and its *p*- and *m*-nitro derivatives. F. I. Berezovskaya, O. N. Semikhatova and G. D. Ostrer. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **9**, 3-16(in Russian, 17; in German, 18-19)(1938); cf. *C. A.* **31**, 4207⁷.—In the decompn. of BzO_2 and its *m*- and *p*-nitro derivs. in acetone of various concns. the order of the reaction is not clear and the values of K did not agree. The values of Q were 10,000, 6000 and 9000 cals. for the BzO_2, the *m*-, and *p*-nitro derivs., resp. Decompn. in 80% HOAc in the presence of NaOAc is of the first order. The values of K were close for all the peroxides and the energy of activation of BzO_2 was 1000 cal. more than for the nitro derivs. The position of the nitro group has no effect upon the energy of activation. The values of K were considerably greater during decompn. on Pt in NaOAc than without Pt. B. Z. K.

The alkaline saponification of polyvinyl acetates. A. Skrabal. *Z. physik. Chem.* **A185**, 389-92(1939).—The observations of Lee and Sakurada (*C. A.* **33**, 7652⁸) are discussed. It is suggested that the sapon. may be a 2-stage reaction. In the first, a very rapid reaction, the acetate reacts with the MeOH under the catalytic influence of NaOAc. In the second, a measurably slow reaction, the MeOAc produced in the first reaction is sapond. L. and S. apparently measured the rate of the second reaction; this is independent of the nature of the original ester. T. H. Dunkelberger

Hydrolysis and alcoholysis. Walter Hückel. *Ann.* **540**, 274-84(1939).—A theoretical discussion of the hydrolysis of chlorides such as CCl_4, $SiCl_4$, PCl_5, SF_6, BCl_3, PCl_3, SO_2Cl_2, $ClSO_3H$, $POCl_3$ and AcCl. C. J. West

The energy and entropy of activation of the hydrolysis of ethyl orthoformate in deuterium oxide. Frank Brescia and Victor K. La Mer. *J. Am. Chem. Soc.* **62**, 612-14 (1940).—The rate of hydrolysis of Et orthoformate was measured at 14.977 and 35.008° in H_2O and in D_2O. An increase of three-fold is observed in the reaction rate, whereas, the observed difference in the energy of activation predicts a nine-fold increase. It is concluded, therefore, that the energy of activation is an important factor in detg. the ratio of the 2 rates. A. B. Garrett

Velocity of formation of ammonium cinnamate. Dora Markowska. *Compt. rend.* **210**, 291-3(1940); cf. *C. A.* **33**, 5732²,³.—The cinnamic acid was pulverized and sifted so that the diam. of its grains was 15-65μ, most being 40-45μ. NH_3 dried over KOH was passed over it. The results, shown by curves, give Valensi's equation (*C. A.* **31**, 6087⁷) as $F(m) = 7.289 - (1 - m)^{2/3} - 6.289(1 + 0.150m)^{2/3} = Kt/c_0$, the symbols having the same meaning as before. The d^{15}_{15} of NH_4 cinnamate is 1.2006. C. A. Silberrad

The replacement of aromatic chlorine by the amino group. VI. Kinetics of the interaction of *m*-nitrochlorobenzene with aqueous ammonia. N. N. Vorozhtsov, Jr., and V. A. Kobelev. *J. Gen. Chem.* (U. S. S. R.) **9**, 1465-7 (1939); cf. *C. A.* **33**, 8580⁹.—Unlike *o*- and *p*-$O_2NC_6H_4Cl$ the *m*-isomer (I) does not react at all with aq. NH_3 at 200° and but slightly (3%) at 230°. In the presence of $CuCl_2.2H_2O$ the rate of ammonolysis is directly proportional to the concn. of I and the catalyst and is independent of the NH_4OH concn. The energy of activation of the reaction is 13,700. The const. of the reaction velocity can be represented by the equation: $\log K = 5.387 - (2933/T)$. **VII. Kinetics of the interaction of β-chloroanthraquinone with aqueous ammonia.** *Ibid.* 1515-16.—The rate of reaction of β-chloroanthraquinone with aq. NH_3 is directly proportional to the concn. of both reactants. The energy of activation of the reaction is 20,500. The const. of the reaction velocity is: $\log K = 6.26 - (4467/T)$. At 210° the velocity const. is 10.37×10^{-4}. The reaction is best effected in the presence of the $Cu(NO_3)_2$ catalyst (cf. Vorozhtsov and Nikitin, *C. A.* **32**, 539⁵). **VIII. Kinetics of the interaction of *p*-chloroaniline, 1-chloronaphthalene and sodium 1,4-chloronaphthalenesul-**

fonate with aqueous ammonia in the presence of copper chloride. *Ibid.* 1569–76.—The rate of reaction of *p*-$ClC_6H_4NH_2$ (I), 1-$C_{10}H_7Cl$ (II) and 1,4-$ClC_{10}H_6SO_3Na$ (III) with aq. NH_3 in the presence of $CuCl_2$ is directly proportional to the concn. of the org. chlorides and the catalyst and is independent of the NH_4OH concn. The cumulative evidence of this investigation series shows that in the catalytic interaction with NH_4OH the org. Cl derivs. form the intermediate complex $RCl.Cu(NH_3)_2$ which then reacts with excess NH_4OH to give aromatic amines. The energy of activation of the reaction of I, II and III, resp., are: 12,500, 12,000 and 12,200. The corresponding consts. of the reaction velocity can be represented by the equations: $\log K = 4.95 - (2732/T)$; $\log K = 3.98 - (2632/T)$, and $\log K = 4.314 - (2677/T) \pm 0.005$. The soly. of II in NH_4OH is greater than in H_2O and increases with NH_4OH concn. Chas. Blanc 1

The heterogeneous catalytic decomposition of hydrogen peroxide in heavy water. P. A. Giguere and O. Maass. *Can. J. Research* **18, B**, 84–9(1940).—The catalytic decompn. of H_2O_2 dissolved in heavy water, both on the surface of glass in alk. medium and on metallic gold, was measured at 35°. The results, compared with those obtained under similar conditions for H_2O_2 in ordinary water, indicate that D_2O_2 is much more stable than ordinary H_2O_2 toward such catalysts. The exptl. results in both cases are of interest chiefly for comparison, and further investigations will be necessary before any sound conclusion can be drawn regarding the mechanism of the reactions involved. J. W. Shipley 2

Catalysis by metallized bentonites. Geoffrey Broughton. *J. Phys. Chem.* **44**, 180–4(1940).—The relative activities of a no. of metallized bentonites were detd. for the catalytic decompn. of H_2O_2 and of isopropyl alc., and the polymerization of pinene. P. H. Emmett 3

High-temperature oxidation of carbon monoxide catalyzed by quartz surface. Yukio Kondo and Osamu Toyama. *Rev. Phys. Chem Japan* **13**, 166–75(1939).—The reaction between CO and O_2 was studied by a static method in the region above the upper explosion limit in a quartz vessel. CO_2 has a retarding effect unless its pressure is low, whereas O_2 favors the reaction. Water is a powerful inhibitor, though its effect falls off with increase in pressure of water vapor. The energy of activation in the absence of water is about 7000 cal. per mole. The results, which differ considerably from those of Hinshelwood and his coworkers, are explained on the assumption of a heterogeneous mechanism. The rate-detg. process is assumed to be a bimol. reaction between CO and O_2 adsorbed on the SiO_2 wall. The retarding effects of CO_2 and water are due to their strong adsorption. J. H. Reedy 4

Decomposition of ammonia by iron catalyst. (Preliminary report.) Katumi Seya. *Rev. Phys. Chem. Japan* **13**, 137–44(1939).—The decompn. velocity of NH_3 in the presence of reduced Fe was measured at 390°–430° by a static method. The K-v curve is complex and seems to indicate a retarded form at the initial stage, followed by a zero order and another retarded form. It is suggested that the retarding action is due to a coating of Fe_xN over the active catalyst. J. H. Reedy 5

Decomposition of ammonia by iron catalyst mixed with alumina and potassium oxide. Ryo Kiyama. *Rev. Phys. Chem. Japan* **13**, 125–36(1939).—The decompn. of NH_3 on various compns. of Fe_3O_4, Al_2O_3 and K_2O in glass vessels was measured at 300°–500° by means of a spring manometer. The reduction velocity of the catalyst was measured by weighing the water formed when H_2 was passed at a given rate through the reaction vessel. The results were interpreted by applying Langmuir's formula to the assumed reactants, and it was found that the reaction consists of (1) a retarded form, followed by (2) a first-order reaction and then (3) a zero or fractional order. The compn. of the catalyst was varied, and the effects were noted on the velocity of the reaction, the adsorption of H_2 and N_2, the relation between activity and adsorption coeffs., the influence of velocity of decompn. by H_2 and N_2, and poisoning by CO. J. H. Reedy 6

Phase diagram of a mixture of natural gas and natural gasoline near the critical conditions. D. L. Katz, D. J. Vink and R. A. David. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1114**, 11 pp.(1939).—A phase diagram showing boundary curve and quantity of liquid in the 2-phase region was detd. for a mixt. of natural gas and natural gasoline at 85–212°F. and 1300–2600 lb. per sq. in. Crit. conditions were observed at 169.5°F. and 2615 lb. per sq. in. abs. Color phenomena were observed in the region of the boundary curve for 102° to 192°F. Approx. ds. of the single-phase and 2-phase regions and analysis of the system are included. Alden H. Emery 7

The system benzene–nitrogen. Liquid-vapor phase equilibria at elevated pressures. Philip Miller and Barnett F. Dodge. *Ind. Eng. Chem.* **32**, 434–8(1940).—At 30–150° N was bubbled through liquid benzene at pressures up to 300 atms. and samples of the liquid and gas phases were analyzed. The soly. of N in benzene increases with temp., the effect increasing at higher pressures. The data agree more closely with Henry's law at the higher temps., but only approx. in any case. When the mol. fraction of benzene in the gas phase is plotted against the pressure, a min. appears which occurs at higher pressures as the temp. increases. The "cricondentherm" pressure is relatively low compared to the crit. pressures. W. B. Keighton 8

Equilibria in liquid iron with carbon and silicon. L. S. Darken. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1163**, 18 pp. (1940). If it is assumed that Fe_3C and Fe_3Si are present in molten Fe contg. C and Si, it is possible to express exptl. data satisfactorily by a simple equil. expression and to bring into harmony data referring to different reactions in liquid Fe. These data include soly. of graphite in liquid Fe and in Fe-Al and Fe-Si melts; vapor pressure of the Fe-C system at high temps. and the CO-CO_2 ratio in equil. with them; heat of formation of FeC; equil. between Si and Mn in low-C molten steels and the resp. oxides in the slag phase, and the deoxidizing characteristics of Si. The consistency of the results of the calcns. indicates that the use of the simple form of the law of mass action is justified in the treatment of data on solns. in liquid Fe provided that compd. formation in the liquid is taken into account. The interpretation proposed not valid over 15% Si, probably because of the presence of compds. other than Fe_3Si. Alden H. Emery 9

Investigation in the field of basic chlorides. I. G. B. Fridman. *J. Gen. Chem.* (U. S. S. R.) **9**, 1598–1602 (1939); cf. *C. A.* **29**, 6667⁴.—The system ZnO–$ZnCl_2$–H_2O was studied at 30°. The solid phases were examd. by the Schreinemakers' "rest" method. The usual method of diagram analysis "compn.-property" of the system can be used, because it does not form solid phases of colloidal structure. The data obtained do not confirm the existence of any of the Zn oxychlorides cited in the literature. At the state of equil. the system forms only 1 oxychloride, $5ZnCl_2.5ZnO.8H_2O$, with stability limits from 57.7 to 71% $ZnCl_2$ in the liquid phase. The 2nd solid phase forms a solid soln. with stability limits from 9.28 to 55% $ZnCl_2$ in the liquid phase. At lower $ZnCl_2$ concns. the solid soln. is decompd. to form continuous series of solid solns. The hardening products of Zn cements from $ZnCl_2$ are the solid solns. of limit concn. Chas. Blanc 10

The system calcium oxide–silica–water at 30°. The association of silicate ion in dilute alkaline solution. Paul S. Roller and Guy Ervin, Jr. *J. Am. Chem. Soc.* **62**, 461–71(1940).—Measurements are made of the ratio of CaO to SiO_2 in the solid phase, and of the concn. of CaO and SiO_2 in soln. at 30.2°. The data indicate 4 phase ranges; in 2 of these the concns. are invariant. Adsorption of CaO by solid phase occurred throughout. The compns. of the hydrated compds. were (1) $CaO.SiO_2$-($CaH_2Si_2O_4$), (2) $3CaO.4SiO_2(Ca_3(HSi_2O_6)_2)$, (3) $CaO.2SiO_2$ and $CaH_2Si_2O_6$ or $Ca(HSiO_3)_2$). The invariant concns. for the mixt. of (1) and (2) were: 3.09 millimoles CaO/l. and 0.090 millimoles SiO_2/l., and for the mixt. of (2) and (3), 0.900 millimoles CaO/l. and 0.931 millimole SiO_2/l. It is necessary to assume that assocn. takes place in the dil. alk. solns.; the ion species present are $H_3SiO_4^-$ and $H_3Si_2O_6^{--}$. The assocn. const., soly.

product const. and one of the ionization consts., were calcd.; the assocn. const. indicates a high tendency toward assocn. A. B. Garrett

The ternary system: isopropyl alcohol, toluene and water at 25°. E. Roger Washburn and Albert E. Beguin. *J. Am. Chem. Soc.* **62**, 579–81(1940).—The soly. relations and the *n*s of the satd. solns. were detd. Tables are given of solubilities and *n*s and concns. of alc. in conjugate solns. at 25°. A comparison is made of the soly. curve of this system with those of systems contg. CH_3OH and C_2H_5OH (cf. *C. A.* **32**, 4165; **33**, 7656[7]); isopropyl alc. is the most efficient and CH_3OH is the least efficient in bringing about miscibility in toluene–water systems; this is in accord with what is to be expected as detd. by the internal pressures, dielec. consts. and dipole moments of the resp. alcs. A. B. G.

The quaternary system calcium hypochlorite, calcium chloride, calcium hydroxide and water. J. Ourisson. *Atti X° congr. intern. chim.* **4**, 40–51(1939).—Measurements made at 10°, 20°, 30° and 40° are given in graphs. At 10° a new, solid phase appears, tribasic hypochlorite (I), existing between $Ca(OH)_2$ and dibasic hypochlorite. The domain of existence of $Ca(OH)_2$ is appreciably diminished by the appearance of I. The other solid phases are the same as at 20°, but their domain of existence is very different; that of tribasic chloride is increased at the expense of $Ca(OH)_2$, and that of monobasic chloride and 2/3 basic hypochlorite diminished. The 30° diagram is like that at 20°, the domain of existence of tribasic chloride diminishing in favor of $Ca(OH)_2$ and monobasic chloride increasing at the expense of tribasic chloride. The band of 2/3 basic hypochlorite extends farther into the domain of $CaCl_2$ at low concn. At 40° the tribasic chloride disappears, in favor of hydroxide and monobasic chloride. The 2/3 basic hypochlorite is already stable in solns. free from $CaCl_2$. E. M. Symmes

The reciprocal salt pair, $CoSO_4 + (KCl)_2 \rightleftarrows CoCl_2 + K_2SO_4$. II. A. Benrath and G. Ritter. *J. prakt. Chem.* **154**, 40–56(1939); cf. *C. A.* **33**, 5272[6]. The polytherms of the system were detd. from the polytherms of the following component systems: (I) $(KCl)_2$–K_2SO_4–H_2O, (II) $(KCl)_2$–$CoCl_2$–H_2O, (III) $CoCl_2$–$CoSO_4$–H_2O, (IV) $CoSO_4$–K_2SO_4–H_2O. I has already been worked out by Cornec and Hering (*Caliche* **8**, 58(1926)). The isotherms for II were detd. for 0°, 38°, 50°, 51°, 75° and 100°. Below 38° the solid phase is a mixt. of $CoCl_2.6H_2O$ and KCl. At about 45° $CoCl_2.4H_2O$ begins to sep., and above 50° the mixed crystal $CoCl_2.KCl.2H_2O$. At higher temps. the $CoCl_2$ content of the solid phase increases, just as if $CoCl_2$ was dispersed in the mixed salt as a dispersion medium. At 100° a blue salt appears, in which KCl acts as the dispersion medium. The isotherms for III as worked out by Benrath (cf. *C. A.* **33**, 5272[6]) have been modified. Equil. is reached with difficulty in systems contg. $CoSO_4.H_2O$, since this monohydrate forms slowly. It is better to use freshly prepd. $CoSO_4.H_2O$. In IV the schonite form, $CoSO_4.K_2SO_4.H_2O$, seps. slowly at 94°, owing to the slow dehydration of the higher hydrates. The leonite form, $CoSO_4.K_2SO_4.4H_2O$, appears first at 97° as ruby-red rod-like crystals. At 100° this goes over into the schonite form. From the data for these 4 salt pairs, polytherms for the over-all system were constructed as 3-dimensional curves, compns. being plotted on the quadrilateral base, and the temps. as vertical ordinates. J. H. Reedy

The specific heats of some solid aromatic acids and their ammonium salts and the atomic heat of nitrogen. Syuniti Satō and Tatuyosi Sogabe. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 449–57(1939); cf. *C. A.* **33**, 8099[1].—Mol. heat capacity measurements were extended to the aromatic acids, benzoic, cinnamic, *o*-phthalic and *m*-phthalic, and to their NH_4 salts. The at. heat of N deduced from the difference in the mol. heat capacities of corresponding acid NH_4 and neutral NH_4 salts is smallest (1.7) for the aromatic and largest (6.4) for the aliphatic compds.; that deduced from the corresponding acids and acid NH_4 salts is largest (5.3) for the aromatic and smallest (1.8) for the aliphatic compds. The intermediate values obtained from the acids and the neutral NH_4 salts (aromatic, 3.3, and aliphatic, 4.2), are near the provisional value, 3.5, obtained from the various nitrides. L. E. Steiner

The use of the method of thermal analysis. V. A. Kind, S. D. Okorokov and E. P. Khodikel. *Tsement* **6**, No. 7, 32–7(1939).—Dehydration curves were obtained with the aid of a device, suggested by N. S. Kurnakov, photographically registering galvanometer readings. The differential method of detg. temp. intervals in which definite chem. processes take place in thermally treated matter was used. Observations were made with hydrated tricalcium silicate, β-dicalcium silicate, tricalcium aluminate, dicalcium ferrite, brownmillerite, and Ca hydrosilicate and hydroaluminate obtained synthetically in aq. medium, and dehydration curves are shown graphically. The method is a good means for the investigation of dehydration processes. E. E. Stefanowsky

Variation at constant temperature as a function of concentration of the differential heat of solution of normal organic substances in dilute aqueous solution. Jean Perrin. *Compt. rend.* **210**, 293–5(1940).—If p_A g. of a normal org. substance, A, of mol. wt. m_A, is dissolved in 100 g. H_2O the mol. concn. $c_A = (p_A/m_A)/(100/18) = 18p_A/100m_A$. If q_{c_A} is the differential mol. heat of soln. of A in a soln. of concn. c_1 at T, q_{c_1} is a function of T and of c_1; and if Δq_{c_A} is the variation of q_{c_A} when the concn. increases from 0 to c_A, then $\Delta q_{c_A}/m_A = 18kp_1/100m_1$. Putting $\Delta q_{c_A}/m_A = \delta q_{c_1}$, and $K = 18k$, then $\delta q_{c_A} = Kp_A/100m_A$. The relation is proved to hold for dil. solns. ($p = 0$ 10%) of urea, acetamide, mannitol, glucose, sucrose, glycol and glycerol, K being sensibly = the cryoscopic const. of H_2O. These results provide a means of detg. the mol. wt. of the dissolved substance, as $m_A = Kp_1/100\delta q_{c_A}$. Better results are obtained by using an org. solvent in place of H_2O, as K is then higher. C. A. Silberrad

The heats of solution, heats of formation, specific heats and equilibrium diagrams of certain molecular compounds. A. N. Campbell and A. J. R. Campbell. *J. Am. Chem. Soc.* **62**, 291–7(1940). The thermal values were detd. in order to obtain some measure of the energy change involved in the formation of org. addn. compds. Expt. detns. were made, for reactants and products, of heat of soln., specific heat and soly.-equilibria (in the case of salicylic acid–acetamide–H_2O) were made for the systems phenol urea, phenol-*p*-toluidine, β-naphthylamine-*p*-nitrosodimethylaniline, and salicylic acid–acetamide. The heats of formation of addn. compds. are calcd. at room temp. and at abs. zero. The equil. diagrams for the systems phenol urea–H_2O and salicylic acid–acetamide–H_2O indicate that the addn. compd. is stable at room temp. A. B. Garrett

The heat of dilution of aqueous hydrochloric acid at 25°. Julian M. Sturtevant. *J. Am. Chem. Soc.* **62**, 584–7(1940).—The heat of dilu. was measured up to a concn. of 3.3 molal. From these data the apparent and partial relative molal heat content of the solute, and the partial relative molal heat content of the solvent were calcd.; tables of their values and of the integral heats of dilu. of HCl solns. at 25° are given. A. B. Garrett

Salt hydrates and deuterates. II. Correlation of heats of dissociation and structure. James Bell. *J. Chem. Soc.* **1940**, 72–4; cf. *C. A.* **31**, 4508[4].—Dissocn. pressures of the following compds. were measured between 20° and 40°: $NiSO_4.7D_2O$, $NiSO_4.7H_2O$, $CoSO_4.7D_2O$, $ZnSO_4.7D_2O$, $ZnSO_4.7H_2O$, $CuCl_2.2D_2O$, $BaCl_2.2D_2O$, $KF.2D_2O$, $KF.2H_2O$. A table of the consts. A and B of the relation $\log p = A - B/T$ together with the heats of dissocn. ($L = 4.575\,B$) is given for all salts thus far examd. In all cases the heat of dissocn. of the deuterate is greater than that of the hydrate by an amt. more than can be accounted for on the basis of the difference between the heats of vaporization of H_2O and D_2O. This may be regarded as evidence that water in a normal hydrate is bound by ordinary covalent or van der Waals forces and

not by special resonance linkages such as hydrogen bonds. Measurements are given of the dissocn. pressures of $D_2C_2O_4.2D_2O$ and of $H_2C_2O_4.2H_2O$. The corresponding vapor-pressure equations are: $\log p = 10.27 - 2910/T$ and $\log p = 10.45 - 2983/T$. The mean value of the ratio p_{D_2O}/p_{H_2O} is 1.09. This indicates a weakening of the hydrogen bond between H_2O and carbonyl O on introduction of D. A table is given of the mol. vols. of $H_2C_2O_4.2H_2O$, $D_2C_2O_4.2D_2O$, KH_2PO_4 and KD_2PO_4, and of the hydrates and deuterates of $CuSO_4$, Li_2SO_4, $CoSO_4$, $CoCl_2$ and $SrCl_2$. It is suggested that the expansion of mol. vol. on substitution of H by D may indicate the presence of hydrogen bonds, but that the reverse is not necessarily true. H. C. Thomas 1

The evolution of red giants. G. Gamow. *Phys. Rev.* **55**, 796–7(1939); cf. preceding abstr.—The distribution of red giant stars on the *R-L* diagram is discussed. G. M. Petty

Physical possibilities of stellar evolution. G. Gamow. *Phys. Rev.* **55**, 718–25(1939).—The evolution of gaseous

bodies, caused by different phys. processes happening in their interior and serving as energy sources, is considered qualitatively and, partially quantitatively in view of possible applications for the explanation of various observed states of known stars. G. M. Petty

Energy production in red giants. G. Gamow and E. Teller. *Phys. Rev.* **55**, 791(1939); cf. preceding abstr.—The energy release and capture probability for some of the reactions between light elements are tabulated. These data are plotted on a log L/L —log R/R diagram (L = luminosity, R = radius) together with data for some pulsating variable stars. G. M. Petty

Calculation of the energy of repulsion. M. F. Maimotenko. *Acta Physicochim.* U. R. S. S. **11**, 225–38; *J. Exptl. Theoret. Phys.* (U. S. S. R.) **9**, 775–82(1939) (in English); cf. *C. A.* **33**, 7631[4].—By the method of orthogonalization, the many-electron problem reduces to several one-electron problems. The method gives essentially the same results as that of Heitler-London; the lattice and lattice-energy consts. of Ne and A so calcd. agree well with exptl. data. F. H. Rathmann

Production of bursts and the spin of the meson. H. J. Bhabha, H. Carmichael and C. N. Chou. *Proc. Indian Acad. Sci.* **10A**, 221–3(1939); cf. *C. A.* **32**, 3691[7]; **33**, 3675[7].—Since it is now generally considered that the meson has a spin of one unit, the older calcns. are revised. A table of the probability that a meson of given energy will emerge from air or Pb accompanied by a shower of more than N particles (N = 10, 100 or 1000) is calcd. for spins of $^1/_2$ and 1. The new theory (spin = 1) agrees much better with expt. than the old theory. G. M. P.

Determination of h/e by the method of isochromats. Per Ohlin. *Nature* **145**, 223(1940).—Detns. of h/e from the short-wave-length limit of the continuous x-ray spectrum give results which disagree with the value of h measured by other methods. The shape of the isochromats changes with the pressure in the x-ray tube: at 5×10^{-4} mm. the usual shape is obtained; at 1.5×10^{-5} mm. the isochromat runs straight to zero, giving a sharp short-wave-length limit. For an accurate detn. of h/e by this method, the pressure must be carefully controlled. G. M. Petty

Scattering and polarization of electrons. M. E. Rose. *Phys. Rev.* **57**, 280–8(1940).—An attempt is made to account for the small polarization of electrons and the anomalously small scattering of fast electrons in double scattering in heavy materials by assuming non-Coulombian forces near the nucleus. Very special forces would be required such as: only the $p_{1/2}$ wave at high energies or both waves scattered at all energies with large interaction and special dependence. The anomalous scattering and asymmetry must be explained on grounds other than non-Coulombian forces. F. E. Brown

Energy states of the valence electrons in some metals. I. 11. The nature of the anomalies of zinc and its electronic structure in condensed states. Mituru Satô. *Science Repts. Tôhoku Imp. Univ.*, First Series., **28**, 143–96(1939); cf. *C. A.* **33**, 1131[8].—The abs. temp. of a solid is a measure of the energy of thermal vibration. The temps. at which Zn shows anomalous phys. properties are related to the crystal energy levels of the solid. S. Bradford Stone

Splitting of heavy atom nuclei by neutrons. C. J. Bakker. *Nederland. Tijdschr. Natuurkunde* **6**, 333–45 (1939).—A review of the work of Hahn and Strassmann on U disintegration, references. B. J. C. v. d. H.

Properties common to hydrogen-containing molecules. Henri Deslandres. *Compt. rend.* **210**, 277–81(1940); cf. *C. A.* **34**, 1250[3].—D.'s views are further elaborated. C. A. Silberrad

Modern quantum mechanics and the benzene problem. V. G. Elsen. *Chem. Weekblad* **37**, 39–48(1940); cf. *C. A.* **34**, 935[9].—A continuation of previous discussions on the nature of single and double bonds. H. S. v. K.

Variation with temperature of the maximum of the emissive power of nickel. F. Cennamo. *Nuovo cimento* **16**, 294–8(1939); cf. *C. A.* **33**, 9132[9].—The variation of emissive power is calcd. as $e_{\lambda m} = k\ T^{5.85}$, which is confirmed by expt. J. B. Austin

Thermionic constants of tungsten as a function of crystallographic direction. M. H. Nichols. *Phys. Rev.* **57**, 297–306(1940).—Recrystn. of W wire into single crystals with a face-diagonal parallel to the wire axis is described. The emission is fitted to an empirical equation and the values therein are discussed. Gregg M. Evans

Fluctuation of thermionic current and the "flicker" effect. M. Surdin. *J. phys. radium* **10**, 188–9(1939).—Math. The fluctuation of the thermionic current of the "flicker" effect can be attributed to the fluctuation in the no. of free electrons in the metal. B. C. P. A.

Threshold potentials and reactivity under electric discharge. S. S. Joshi. *Current Sci.* **8**, 548–9(1940).—A sudden change (generally increase) in current and wattage indicates arrival at a threshold potential (Vm) necessary for the initiation of a reaction in an ozonizer. Variations of Vm with time may be used to trace the progress of a series of reactions. Gregg M. Evans

The distribution of electrons over the section of a gas discharge. V. A. Fabrikant. *Compt. rend. acad. sci. U. R. S. S.* **24**, 531–3(1939)(in English).—Theoretical. A soln. of the differential equation occurring in Schottsky's diffusion theory (cf. *C. A.* **19**, 1091) is given and the theoretical results are analyzed with respect to cumulative ionization, direct ionization and recombination during triple collisions. Frank Gonet

Theoretical and experimental investigations on the influence of electron partial pressures in low-pressure columns. Max Steenbeck. *Wiss. Veroffentl. Siemens-Werken* **18**, No. 3, 91–112(1939).—Electron gas in a low-pressure discharge column exerts a mech. pressure corresponding to that for an ordinary gas at the electron temp. and concn. Because of the small ion temp., ion gas pressures are negligible compared with the electron and the neutral gas pressures. Over the cross section of a low-pressure discharge column the sum of the partial pressures of the electron, ion and neutral gases is const. Since the electron and ion gas pressures in the center of the column are greater than at the edge, the pressure of the neutral gas in the center is correspondingly smaller. The electron gas pressure must always remain smaller than the total pressure as measured with an external manometer. The law of the constancy of the sum of the partial pressures is confirmed experimentally, so that the effect of the electron gas can be shown with ordinary manometers. L. E. Steiner

First Benedicks effect in gas-free mercury, as influenced by the mean temperature. C. Benedicks and P. Sederholm. *Nature* **145**, 148(1940); cf. *C. A.* **32**, 6942[4].—The first Benedicks effect in gas-free Hg increases rapidly with increase of the mean temp. The law of increase is similar to Richardson's law for the emission of electrons into a vacuum. G. M. Petty

An experimental determination of the electron affinity of chlorine. J. J. Mitchell and Joseph E. Mayer. *J. Chem. Phys.* **8**, 282–5(1940).—The electron affinity of Cl was detd. to be about 92.7 kg.-cal. by measuring the ratio of ions to electrons and atoms leaving a hot W surface (~2000°K.). Owing to the reactivity of the Cl an erratic behavior leads to skepticism as to the accuracy of the result. G. M. Petty

Single scattering of fast β-particles in argon. II. E. Stepanova. *J. Phys.* (U. S. S. R.) **1**, 203–6(1939). See *C. A* **33**, 5281[9]. A. D.

Multiple scattering of fast electrons. C. W. Sheppard and W. A. Fowler. *Phys. Rev.* **57**, 273–80(1940); cf. *C. A.* **33**, 466[9], 8492[1].—The scattering of electrons and positrons of energy 5–17 m. e. v. was measured in foils of Pb 0.15 and 0.38 mm., of Al 1.18 mm. and laminae of C 1.32 and 3.81 mm. in thickness. The scattering is in agreement with the multiple scattering theory of Williams (*C. A.* **33**, 8492[1]) except in the magnitude of the scattering in Al and Pb, in which the exptl. results are only 85% and 60% of the theoretical predictions. Eight figures and 3 tables summarize data from 52,000 cloud-chamber pictures. F. E. Brown

Scattering of fast electrons through large angles. A. I. Alikhanov, A. I. Alikhan'yan and M. S. Kozodaev. *Compt. rend. acad. sci. U. R. S. S.* **24**, 525–7(1939) (in English).—The single scattering of electrons, through an angle of 90°, with energies from 600 to 2000 e. kv. was investigated with an aim of verifying Mott's formula. A homogeneous beam of electrons from a magnetic spectrograph was caused to impinge on a thin foil of various thicknesses of celluloid, Al, Cu and Au placed at an angle of 45° to the beam, and the scattered electrons were registered by the coincidence of simultaneous discharge in 2 Geiger-Muller counters placed at an angle of 90° with respect to the beam. The authors found $\sigma_{exptl.}$ to be equal to 0.31, 0.0, 5.6 and 78 ($\sigma_{theor.}$ = 0.29, 1, 6, 178) for celluloid, Al, Cu and Au, resp., and they conclude that with the exception of Au the large-angle scattering of electrons with energies of the order of 1000 e. kv. is in good agreement with quantum-mech. considerations. F. G. 1

Production of positive electrons by β-particles. G. J. Sizoo and F. Barendregt. *Physica* **6**, 1085–1100(1939) (in English).—Cloud-chamber expts. detg. the intensity and energy distribution of positrons emitted by Ra(B + C) agree with values given by Chadwick, Blackett and Occhialini (cf. *C. A.* **28**, 2991[8]). The calcd. no. of positrons excited by internal pair production by the theory of Jaeger and Hulme (cf. *C. A.* **32**, 8914[7]) was one ninetieth of the observed. Most of the positrons have energies 2 less than 300 kv. The positrons excited in lead by the β and γ radiation of Ra(B + C) were investigated with a Wilson cloud chamber. In this way it is shown that only a small fraction of the positrons observed can be due to external pair production. G. W. King

Total secondary electron emission from polycrystalline nickel, sodium chloride and potassium chloride. Hikoo Saegusa and Tutomu Matumoto. *Science Repts. Tôhoku Imp. Univ.*, First Ser. **28**, 215–60(1939).—Ni has several peaks at low voltages. NaCl has peaks at 11 and at 23 v. KCl has a peak at 7 v. S. Bradford Stone 3

Secondary emission of electrons. N. L. Yasnopol'skiĭ and G. A. Tyagunov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1573–82(1939). Theoretical. Secondary electrons are produced in metals by Coulomb interaction between primary electrons and free electrons, and in dielectrics by ionization. A general consideration of these mechanisms allows an estn. of the relation between the no. of secondary electrons and their energy. The results are in a qual. agreement with expts. J. J. Bikerman 4

Distribution of velocities of secondary electrons emitted by sodium chloride. M. M. Vudynskiĭ. *J. Tech. Phys.* (U. S. S. R.) **9**, 1583–8(1939); cf. *C. A.* **33**, 7660[9]. The relation between the no. *N* of secondary electrons and their energy is for hot NaCl practically identical with that for metals; the max. of *N* is observed at 0.5 –1 e. v. and its position is independent of the energy of the primary electrons (300–1500 e. v.). When the temp. of NaCl decreases the no. of slow electrons increases and the max. of *N* is less pronounced. J. J. Bikerman 5

Secondary emission of electrons from mercury. Yu. M. Kushnir, V. I. Milyutin and V. P. Goncharov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1589–91(1939).—The secondary emission of liquid Hg at 5° is identical with that of solid Hg at −80 and −196°. Air shifts the max. of emission from 700 to 400 e. v. J. J. Bikerman 6

The secondary emission factor for insulators irradiated with electrons. H. Salow. *Z. tech. Physik* **21**, 8–15 (1940).—The variation of secondary emission with the velocity of the primary electrons is detd. for *mica*, *quartz* and *glass*. The characteristics of insulators are very similar to those of a metal. The treatment and purity of the surface have a great influence. J. B. Austin 7

Secondary electron emission. VI. Influence of externally adsorbed ions and atoms on the secondary electron emission of metals. J. H. de Boer and H. Bruining. *Physica* **6**, 941–50(1939) (in English); cf. *C. A.* **34**, 319[2]. G. W. King 8

β-Rays from radioactive isotopes, Ni^{63}, Zn^{63}, Zn^{65}, Zn^{69}, Zn^{69*}, Ga^{68}, Ga^{70}, Ga^{72}, Ge^{71}, Ge^{75} and Ge^{77}. R. Sagane, S. Kozima and G. Miyamoto. *Proc. Phys.-Math. Soc. Japan* **21**, 728–42(1939) (in English).—The β-ray (electron or positron) spectra of the above listed elements were studied by measuring curvatures of cloud-chamber tracks in a magnetic field. A. O. Allen 9

Further applications of the photographic method in nuclear physics. C. F. Powell *Nature* **145**, 155–7 (1940); cf. *C. A.* **34**, 1243[7].—The method is useful for measuring the energy and direction of neutrons, protons and γ-rays. It gives a permanent record in a thick photographic emulsion of the length and direction of each track. The technique is described in detail. To show applications of the method, data are given for the distribution of 1700 forward neutrons from F + D at 900 kv., for the range-angle distribution of 500 proton tracks scattered by B + D neutrons and for the energy distribution of all tracks projected within 40° of the direction of the incident neutrons. G. M. Petty 10

Cloud chamber with electric automatic control. F. Barendregt and G. J. Sizoo. *Physica* **6**, 1077–84(1939) (in English). G. W. King 11

Radiation measurements in the short-wave ultraviolet by means of the selenium blocking-layer cell. Fritz Rössler. *Z. tech. Physik* **20**, 291–3(1939).—Several methods are described for making such measurements. The most useful is to det. the difference between a filtered and an unfiltered cell. J. B. Austin 12

Influence of metastable atoms on the inertia of gas-filled photocells. N. A. Penn. *J. Tech. Phys.* (U. S. S. R.) **9**, 1712–8(1939).—The amplitude *a* of the intermittent current produced by an intermittent illumination of a K_2S-K cathode in Ne decreases when the frequency increases. At a const. frequency (1500–12,000 cycles) *a* diminishes when the applied voltage rises. Addn. of 0.1% of A lowers *a* at all frequencies, while 0.5 or 1% of A increases *a* at lower frequencies (e. g., 1000 cycles) and lowers it at high frequencies (e. g., 10,000 cycles). The increase of *a* on addn. of A is due to collisions between A and metastable Ne atoms; and the decrease of *a* is explained by the reduction of the ignition voltages by A. J. J. Bikerman 13

The soft component of cosmic rays at sea level. Ig. Tamm and S. Belenky. *J. Phys.* (U. S. S. R.) **1**, 177–98 (1939). S. L. Gerhard 14

An ultrasoft component of cosmic radiation. I. G. P. S. Occhialini and Mario Schönberg. *Ann. acad. brasil. sci.* **11**, 351–5(1939); cf. *C. A.* **33**, 9122[6].—From a study of the ionizing part of cosmic radiation by means of a system of 2 Geiger-Muller counters, it is concluded that the corpuscles of the ultrasoft radiation have energies lower than 5×10^6 e. v., that the ultrasoft radiation has no zenithal effect, and that it constitutes 12% of the total ionizing radiation, within an error of 50%. A. H. K. 15

Shallow tracks [produced] by cosmic rays. A. Zhdanov. *Compt. rend. acad. sci. U. R. S. S.* **22**, 163–5(1939).—At. disintegrations produced by cosmic rays have been studied by the photographic technique previously employed (*C. A.* **33**, 3679[9]). By measuring the lengths of the proton tracks and the curvature of the mesotron tracks the momenta of the various particles have been detd. and the conservation of momentum has been established for a no. of collisions. It is suggested that in addn. to Bohr's liquid drop theory of nuclear disintegration other processes play a part in the interaction of cosmic rays and matter. B. C. P. A. 16

Decay of the penetrating cosmic rays. II. E. M. Bruins. *Proc. Acad. Sci. Amsterdam* **42**, 740–4(1939) (in English); cf. *C. A.* **33**, 6141[6].—The absorption of penetrating cosmic rays and the effect of barometric pressure are calcd. E. O. Wiig 17

The secondary radiation of cosmic rays. Giuseppe Cocconi and Vanna Tongiorgi. *Nuovo cimento* **16**, 447–55 (1939).—The divergence of sheaves is detd. as a function of angular aperture by means of a triple counter. For soft rays the results were as expected. For hard rays the effects observed by Bothe and Schmeiser (*C. A.* **32**, 4872[7]) at small angles were not confirmed. The production of secondary rays from hard rays increases as the at. no. of the producing material decreases. J. B. Austin 18

The secondary γ-radiation ("Bremsstrahlung") excited by the β-Particles of $_{15}P^{32}$. G. J. Sizoo, C. Eijkman and P. Groen. *Physica* **6**, 1057–76(1939)(in English). G. W. King

Production of neutrons by cosmic rays. G. Cocconi and V. Tongiorgi. *Naturwissenschaften* **27**, 211(1939); cf. *C. A.* **34**, 1909[8].—The expts. of Froman, *et al.*, have been repeated, but the occurrence of neutrons to the extent of 30% of the hard component of cosmic rays could not be confirmed. If the effect is real it is much less than this. B. C. P. A.

Further investigation of the γ-rays from cadmium under slow-neutron bombardment. W. H. Jordan *Proc. S Dakota Acad. Sci.* **19**, 75–6(1939); cf. *C. A.* **33**, 1209[5]. — In an attempt to increase the amt. of radiation from Cd, the exptl. procedure previously used was changed so that (1) the paraffin blocks were replaced by a large tank of water in which the neutron source was immersed, (2) small tanks of aq $CdSO_4$ instead of Cd strips were placed near the cloud chamber and (3) $CuSO_4$ soln. was used in control expts. From the results of 20,000 photographs, yielding 60 measurable electron pairs, it was found that (1) the no. of electron pairs was not appreciably increased by the new arrangement, (2) nearly as many pairs were obtained from the $CuSO_4$ soln. as from the Cd and (3) the distribution of the pairs on a graph on which the no. of pairs in a given energy interval is plotted against the energy, is much the same as that observed from Be bombarded by α-particles. It is concluded that any radiation coming from the Cd was completely masked by the radiation from the neutron source and that in measuring γ-rays from Cd, a stronger neutron source (from a high-voltage tube or cyclotron) and one without the intense γ-ray background should be used. George Ayers

Salts of radium mixed with beryllium as a source of neutrons. Z. Ollano. *Nuovo cimento* **16**, 456–8(1939); cf. *C. A.* **33**, 5282[4], 5284[8].—Comparison of the no. of neutrons emitted per sec. per millicurie by two sources composed of mixts. of Ra salts with Be revealed a significant difference which was traced to faulty mixing in one case. J. B. Austin

Measurements of the neutron-proton scattering cross section. Lennart Simons. *Kgl. Danske Videnskab. Selskab, Math.-fys. Medd.* **17**, No. 7, 16 pp.(1940)(in English); cf. *C. A.* **33**, 6142[4].—The cross section for scattering of thermal neutrons by protons in paraffin wax was detd. by using both Ag and I detectors, a Geiger-Muller counter and a Ra + Be neutron source. Results, obtained for different detectors, water layer thicknesses and distances of the detector from the paraffin block, agree within the statistical error. The most probable value of the mean free path of the resonance neutrons in water at room temp was found to be 0.91 cm. If the chem. binding forces were considered this gave a value of 11×10^{-24} sq. cm. for the scattering cross section (σ) of free protons relative to slow neutrons (energies less than 10,000 v.). The cross section for protons in paraffin for neutron energies well above the binding energies of the protons was also measured directly by using the activity produced in various elements as a detector for such neutrons, where the activation was effected through a shield of Cd. The mean free path in paraffin of the "resonance" neutrons of these elements was found to be 1.1 cm., which corresponds to a value of about 11.5×10^{-24} cm. Use of the exptl. value of σ in Wigner's formula (*C. A.* **31**, 4581[7]) gave 99360 e. v for the proper energy of the singlet state of the deuteron. The app. and procedure used are described. Frank Gonet

Angular distribution of neutrons scattered by protons. Tosinosuke Muto. *Proc. Phys.-Math. Soc. Japan* **21**, 808–9(1939)(in English).—Math. A. O. Allen

Note on *p*-wave anomalies in proton-proton scattering. G. Breit, C. Kittel and H. M. Thaxton. *Phys. Rev.* **57**, 255–9(1940); cf. *C. A.* **33**, 6135[5,6], 6142[6].—A comparison of calcd. and observed angular distributions for proton energies of 2.0, 2.4 and 3 m. e. v. indicates that *p*-wave effects predicted by Bethe's neutral form of meson theory with a mass of 180 are too large, since they give too much small-angle scattering. F. E. B.

Inner-shell ionization of atoms by electron impact. E. H. S. Burhop. *Proc. Cambridge Phil. Soc.* **36**, 43–52 (1940).—Calcns. with the Born approximation are made of the ionization by electron impacts of the *K*-shells of Ni, Ag and Hg and of the three *L*-shells of Ag and Hg. Relativistic effects and the exchange between scattered and ejected electrons are neglected. The calcns. are carried out with screened hydrogenic wave functions. The effects of the approximations are discussed. For *K*-shell ionization the agreement with exptl. data is reasonably good. In the case of the *L*-shell the agreement is only fair. H. C. Thomas

An ion-probe of great sharpness. Manfred von Ardenne. *Z. tech. Physik* **20**, 344–6(1939).—An app. for sampling a bundle of canal rays of small cross-section It uses a new electrostatic lens. It has application to the electron microscope and to the study of chem. reactions at a point. J. B. Austin

The interpretation of ionization measurements in gases at high pressures. Elizabeth Kara-Michailova and D. E Lea. *Proc. Cambridge Phil. Soc.* **36**, 101–26(1940). — A theory is described which enables the calcn. of the proportion of ions, as a function of gas pressure and collecting field, escaping recombination in the clusters resulting from ionization by γ-radiation in gases at high pressures The predictions of the cluster recombination theory are shown to be in satisfactory agreement with exptl. data It is shown that the extension of Jaffe's theory of columnar recombination to the case of ionization produced by fast electrons or γ-rays is incorrect. H. C. Thomas

The nuclear mass and radioactivity of $_1H^3$. S. C Sirkar and K. C. Mukherji. *Science and Culture* **5**, 143(1940).—The data of Alvarez and Cornog (*C. A.* **33**, 3196[6]) and of Livingston and Bethe (*C. A.* **31**, 8340[9]) are recalcd. and shown to be compatible. $_1H^3$ emits one electron with small kinetic energy and is transformed into $_2He^3$. The radiation from $_1H^3$ is β-radiation G. M. P.

Bombardment of nitrogen and oxygen with protons. S. C. Curran and J. E Strothers. *Nature* **145**, 224 (1940) —In the reaction $N^{14} + H^1 \rightarrow O^{15} + h\nu$, the yield is 1.5×10^{-11} positrons per proton of energy 0.90×10^6 e. v. The reaction $N^{15} + H^1 \rightarrow O^{16} + h\nu$ could not be detected. In the reaction $O^{16} + H^1 \rightarrow F^{17} + h\nu$, the yield is 8.0×10^{-12} positrons per proton of energy 0.95×10^6 e. v. The relative intensities for the 2 reactions are plotted against proton energies of 550–960 kv. G. M. Petty

Products of the fission of uranium and thorium under neutron bombardment. Lise Meitner and O. R. Frisch *Kgl. Danske Videnskab. Selskab, Math. fys. Medd.* **17**, No. 5, 14 pp.(1939)(in English); cf. *C. A.* **33**, 4869[5]. F. O. Wiig

Fission of uranium nuclei. N. F. Volkov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 528–30(1939)(in English). — Introductory expts. were carried out in an approach to the problem of the existence of transuraniums, based on Bohr's theoretical concepts explaining the fission of Th and U nuclei (*C. A.* **32**, 3253[6]; **33**, 3685[4]). The following expts. were carried out to ascertain whether the process of nuclear fission takes place not only at the very moment of bombardment of U with neutrons, but also somewhat after the bombardment has ceased: (1) 62 g. of Na uranate was bombarded for 24 hrs. by neutrons from the Radium Inst. of the Acad. of Sci. cyclotron, the reaction being $_1D^2 + _1D^2 \rightarrow _2H^3 + _0n^1$. The neutron intensity was approx. that of 20 curies Rn + Be. After bombardment the Na uranate was scattered over an area of 3500 sq. cm., and 2 layers of tissue paper were placed at a distance of 7–10 cm. from the surface of the U. Five hrs. later the paper was removed and burned and the ash measured for activity with a Geiger-Muller counter. The recoil atoms were collected 5 times at 5-hr. intervals and each time the ash showed an activity that gradually decreased with a half-life equal to 6.5 hrs (2) One g. of green U oxide was spread over a surface of 700 sq. cm., surrounded with paraffin and bombarded for 24 hrs. Glass plates were kept 3 mm. from the surface for 4 hrs., then were

removed. Filter paper soaked in 7% HCl was used to wipe the surface facing the U and was dried; it always proved active, showing the same 6.5-hr. half-life period. A control expt., with ordinary U, showed no activity in glass or paper after several days. (3) Fission products of U nuclei bombarded (24 hrs.) by neutrons (20 curies Rn + Be) were collected on glass, by the method of radioactive recoil (cf. Khlopin, Pasvik-Khlopina and V., *C. A.* **34**, 1556[1]). The glass was removed and covered with 2 layers of paper for 2 hrs. The papers touching the glass and the 2nd layer were burned separately and gave 2 half-lives of 4 and 19 hrs., resp. Further work is reported in progress on the examn. of the tracks of subsequent fission of U nuclei and of its heavier products by the method of differential counters, the Wilson cloud chamber and thick-layered photoplates. Also an attempt at discovering the gaseous decay product and detg. its chem. nature is planned. Frank Gonet

Preparation of thin films of uranium and thorium by cathode sputtering. C. C. Van Voorhis *Rev. Sci Instruments* **11**, 77(1940).—Very thin Al foil, which was to be sputtered, was shellacked to a geometrically perforated Al plate 0.05 mm. thick and covered with a similar Al plate 1 mm. thick. This assembly was screwed to a water-cooled Cu plate Square and round rods of U and Th, resp., were used as cathodes instead of thin ribbons, which warped and localized the discharge at one spot on the foil The sputtering was done in an A atm. at 0.1 mm. With a half-wave rectified current of 16–30 ma. at 3000 v. a film of 0.1 mg. U per sq. cm. was deposited in 100 min. H. G Bowlus

Electrocapillary theory of the splitting of heavy elements by slow neutrons. Ya. I. Frenkel. *J. Phys. (U. S. S. R.)* **1**, 125–36(1939).—See *C. A.* **33**, 9115[7]. A. D.

Energies of β-particles from uranium X_2. D. Roaf. *Nature* **145**, 223(1940); cf. *J. Sci. Instruments* **17**, 19 (1940).—When the end-point energy of UX_2 is detd. from the curvature of β ray tracks in a Wilson chamber, the value 1.6 m. e. v. is obtained, in agreement with the value in the "*Tables annuelles de constantes*" **26**, 13(1938). When the energy spectrum of a very thin film of UX_2 is measured with a magnetic spectrometer and coincidence counter, the end point 2.3 m. e. v. is obtained, in agreement with the absorption and magnetic focusing values. G. M. Petty

Radium quantity meter. Robert B. Taft. *Am. J. Roentgenol.* **42**, 900–2(1939).—The Ra is placed between 2 large ionization chambers, and current, amplified by a 6J7 tube, is read on a microammeter. All the parts are assembled in a cabinet for convenient routine use. R. B. Wilsey

Applications of x-ray technique to industrial laboratory problems. H. P. Rooksby. *J. Roy. Soc. Arts* **88**, 308–38(1940).—A review. G. G.

Precision measurement of lattice constants by a compensation method. H. van Bergen. *Ann. Physik* **33**, 737–52(1938); cf. *C. A.* **31**, 7717[8].—The method of Kossel (*C. A.* **30**, 7028[8]) is developed for use with external radiation. B. C. P. A.

Auger and secondary x-ray electrons from gold. R. L. Mayo and H. R. Robinson. *Proc Roy Soc.* (London) **A173**, 192–200(1939).—The energies and approx. relative intensities of the Auger electrons emitted by Au atoms which have been ionized in their *L*-levels are detd. in the magnetic spectrograph. Since more powerful methods than those used here are found to be required to elucidate the complete Auger spectrum, only an incomplete comparison is given of the Auger energies and the energies of the x-ray electrons expelled by primary Au *L*-radiations from normal Au atoms. A new value of $h/e = 1.380_6 \times 10^{-17}$ is deduced from the results of the measurements on the x-ray electron groups. This value is in excellent agreement with that deduced from the Rydberg const. with Bohr's formula. E. O. Wiig

Diffraction of x-rays and electron rays in crystals. I. Theory of structure determination. J. M. Bijvoet and C. H. MacGillavry. *Nederland. Tijdschr. Natuurkunde* **6**, 261–74(1939).—The kinematic theory is dealt with in some detail, including the Fourier and Patterson analysis **II. Results of x-ray analysis. Scattering power of atoms. Diffraction of electron rays.** *Ibid.* 281–99.—A review of miscellaneous results. **III. Dynamic theory. Kossel and Kikuchi lines.** *Ibid.* 301–14. B. J. C. van der Hoeven

Simple photoelectric microdensitometer. M. Spiegel-Adolf and R. H. Peckham. *Ind. Eng. Chem., Anal. Ed.* **12**, 182–4(1940).—The app. makes it possible to give a graphical description of an *x*-ray diffraction pattern. A photoelec. cell mounted on the rack of a microscope stand is illuminated by light passed through the photographic plate. The plate is moved by means of a delicate mech. stage and a position *vs.* relative transmission curve is detd. Measurements can be duplicated to within 2%. T. H. Dunkelberger

The northern lights and the ionosphere. L. Vegard. *Scientia* **67**, 37–43(1940).—The origin of the spectral lines of the aurora borealis is discussed. L. E. Gilson

The β-ray spectrum of radiochlorine. Yuzuru Watase and Zyunkiti Ito. *Proc., Phys.-Math. Soc. Japan* **21**, 626–32(1939).—The β-ray spectrum of radiochlorine (37.3 min.) was investigated with a magnetic spectrometer and found to be composed of 2 clearly resolved groups with excitation levels at 4.99 ± 0.06 m. e. v. and 1.08 ± 0.06 m. e. v. The results are discussed from the point of view of the Fermi and K.-U. (Konopinski-Uhlenbeck) plots. From 2.6 m. e. v. to the end-point of the spectrum, the Fermi plots lay on a straight line; while the K.-U. plots lay on a straight line except near the end-point. Using the absorption method the authors found the max. range of the electrons to be 2.37 g./sq. cm. and conclude that Feather's rule must be revised for higher energies (5 m. e. v.). The authors also show that the radiation is due to a single isotope of radiochlorine and not to 2 sep. isotopes, Cl^{36} and Cl^{38}, having nearly the same periods. Frank Gonet

Emission nebulae in Messier 101. Carl K. Seyfert. *Astrophys. J.* **91**, 261–3(1940).—Ten nebulous objects emitting the Balmer radiations of H and other radiations, such as the 3727 A. line of O II, have been detected in the large late-type spiral nebula *M* 101. C. C. Kiess

A meteor spectrum of high excitation. A. N. Vyssotsky *Astrophys. J.* **91**, 264–6(1940).—Lines of neutral and ionized Fe, Mg, Mn, Cr, Ca and Si have been identified in the spectrum of a high-velocity meteor that flashed in the field of a prismatic camera on Oct. 20, 1939. C. C. Kiess

Double reversal of the *H* and *K* lines in the spectrum of α Bootis. Peter Wellmann. *Z. Astrophys.* **19**, 236–48 (1940).—The *H* and *K* lines of Ca II in the spectrum of this star consist of narrow central absorptions superposed on emission lines which, in turn, are superposed on broad absorptions. The data derived from photometric measurements of these lines suggest the presence in the star's atm. of a layer of Ca vapor of small optical depth but at a temp. about 1000° higher than the surrounding atm. C. C. Kiess

The variable spectrum of α^2 Canum Venaticorum. W. S. Tai. *Monthly Notices Roy. Astron. Soc* **100**, 94–127(1939).—A reinvestigation of the spectrum of this star confirms the previous findings of others that many of its fainter spectrum lines are of variable intensity and belong mainly to 2 groups, the one group being visible when the other is very faint or absent. To group *A* belong lines of Eu II, Dy II, Gd II, Ce II, Ca II, many lines of Ti II, Sr II, Sm II, Y II and Zr II. To group *B* belong the lines of H, Si II, Mg II, Fe II, Cr II. In general the group *B* lines have higher excitation potentials than those of group *A*, indicating that excitation conditions in the star's atm. are variable. C. C. Kiess

Spectral energy curve of the sun in the ultraviolet. Edison Pettit. *Astrophys. J.* **91**, 159–85(1940).—Spectral energy measurements of solar radiation were made both with integrated sunlight and with light only from the center of the sun's disk. The tabulated results reduced to no atm. and giving the no. of w. per sq. m per

100 A. show that from wave length 0.40 to 0.38 μ there is sudden drop of 48% in the solar energy, a nearly const. value from 0.38 to 0.325 μ, followed by a linear fall from 0.325 to 0.292 μ. The atm. transmission coeffs. have been detd. and from them the O_3 content of the earth's atm. has been found to be 0.10 cm. at normal temp. and pressure. Wave lengths and intensities of lines in the O_3 band between 3090 and 3440 A. have also been measured. C. C. Kiess

The hypothesis of the existence of contraterrene matter. V. Rojansky. *Astrophys. J.* **91**, 257–60(1940).—At. theory has led to the conjecture that in some parts of space there may exist atoms whose nuclei are charged negatively and whose extranuclear members are positrons. Such atoms and their constituents and aggregations are designated as contraterrene, while ordinary matter is called terrene. From sym. considerations it is concluded that the spectra of an atom and of its contraterrene counterpart would be identical and that on collision they would annihilate each other with conversion of mass into energy. Expts. are suggested for detecting this energy should it be released in the earth's atm. or in nearby space through encounters of terrene matter with meteoric or cometary bodies composed of contraterrene matter C. C. Kiess

The continuous absorption of light by negative hydrogen ions. II. S. W. Massey and D. R. Bates. *Astrophys. J.* **91**, 202–14(1940).—An accurate theory of the continuous absorption of light by H ions is presented in which various effects not previously considered are included in the calcn. of the absorption coeffs. H ions provide a source of continuous absorption of long-wave radiation which, as shown by Wildt (*C. A.* **34**, 6748), is of importance in the detn. of stellar absorption coeffs. C. C. Kiess

Metastability of hydrogen and helium levels. G. Breit and E. Teller. *Astrophys. J.* **91**, 215–38(1940). The manner in which the mean life-times of H atoms in the 2*s* state and of He in the $1s2s\ ^1S$ state are influenced by the static and dynamic effects of electrons under the pressure conditions of interstellar space is investigated. It is found that the collisional effect is more important than the static leading to a transition probability of the order of $^1/_{600}$ per sec. for electron temps. of about 10,000° and a density of about 30 electrons per cc. C. C. K.

Note on the surface temperature of Venus. Rupert Wildt. *Astrophys. J.* **91**, 266–8(1940).—The amt. of CO_2 in the atm. of Venus has been variously estd. as equiv. to a layer 200 and 400 m. thick under standard conditions of temp. and pressure. An approx. temp. of 408°K. has been found for the planet on the assumption that the CO_2 acts like a perfect reflector for its characteristic radiation, and that the planet's surface behaves like a gray radiator with absorption coeff. $(1-\epsilon)$ for infrared radiation, ϵ being the ratio of the total radiation of CO_2 to that of a black surface of equal temp. C. C. K.

Interaction of atomic energy levels. T. S. Subbaraya, K. Seshadri and N. A. Narayana Rao. *Current Sci.* **8**, 508–10(1939).—Spectrograms of Hg and Zn and of their mixts. were obtained. Three portions of the spectrogram are reproduced, and the effect on each frequency is discussed. II. *Ibid.* **9**, 14–18(1940).—The spectra of Hg, Cd and of their mixts. were studied by the method described previously. At. energy level diagrams are developed, and the weakening or strengthening of the individual lines is discussed. G. M. Petty

The normal electron configuration of singly ionized gadolinium. W. E. Albertson, Hendrik Bruynes and Richard Hanau. *Phys. Rev.* **57**, 292–3(1940).—The normal electron configuration of Gd II is established as $4f^75d6s$. Electrodes composed of a Ag–Gd mixt. were prepd. by pressing and then sintering a Ag powder–Gd salt mixt. With these electrodes, Zeeman-effect photographs were obtained with a field of 81,500 gausses at a dispersion of 0.8 A./mm. throughout the range of λλ 2400–3900 A. Although the Gd lines were fairly faint, several lines were completely resolved, with all of their Zeeman-effect components showing; this enables the unique detn. of both the *J* values and *g* values of the levels involved. Excellent agreement is shown between calcd. and observed Landé *g* values. The fact that all of the fundamental lines of the spectrum are now classified casts serious doubt on the proposition that levels lower than those of the ^{10}D exist. Energy levels and multiplets are given in tables. Edward J. Mahler

Zeeman effect from liquids, solutions of salts of europium. Simon Freed, S. I. Weissman and G. J. Rotariu. *J. Chem. Phys.* **8**, 291(1940).—Zeeman splitting of the absorption lines of aq. solns. of $Eu(NO_3)_3$ near 4650 A. is reported. At 33,000 gausses a sepn. of 7 ± 1.5 cm.$^{-1}$ was obtained. Altogether different results were obtained with solns. of $EuCl_3$. G. M. Petty

Intensities of electronic transitions in molecular spectra. IX. Calculations on the long-wave-length halogen spectra. Robert S. Mulliken. *J. Chem. Phys.* **8**, 234–43(1940); cf. *C. A.* **33**, 8114[2].—Math. The dipole strength D_{NQ} for the perpendicular-type $N \rightarrow Q$ transitions in the long-wave spectra of halogen mols. is computed theoretically according to each of 2 approximations. The atomic orbitals and exptl. values are in good agreement. G. M. Petty

Conditions influencing the intensity of the $^4\Pi-1\ ^1\Sigma$ Cameron bands of CO. Geo. E. Hansche. *Phys. Rev.* **57**, 289–91(1940).—Conditions influencing the intensity in emission in the electrodeless ring discharge have been studied in some 50 exposures planned so as to distinguish between the effects of pressure, power input and frequency. The bands are intense in a large discharge tube at a pressure of about 0.005 mm. or less. Under these conditions the mean free time between collisions of CO mols is 2.5×10^{-5} sec., from which the lifetime of the $^3\Pi$ state is estd. as about 10 microseconds. Marked increases of intensity relative to that of other band systems in the same spectral region are produced by increasing the energy of discharge and by lowering the pressure. This indicates that the excitation function of the Cameron system differs significantly from those of the systems with which it is compared. To illustrate the results, the region 2150–2190 A., cont'g. the Cameron bands, the fourth pos. and the first neg. systems has been chosen, since the quartz spectrograph has good dispersion in this region, and the bands included respond to changes of pressure and power input in a way which is typical of the systems to which they belong. Microphotometer traces of this region photographed under a variety of conditions are shown in 5 figures, for which exposure data are tabulated E. J. Mahler

The predissociation of several diatomic molecules. G. Herzberg and L. G. Mundie. *J. Chem. Phys.* **8**, 263–73(1940).—From the observed anomalous intensity distribution in the S_2 bands it is concluded that the dissocn limit for the first predissocn. of S_2 lies appreciably below the predissocn. limit (4.4 e. v.). The anomalous intensity and the diffuseness persist even at very low pressures (0.01 mm.); this is a case of genuine predissocn. and not pressure broadening, as assumed by Lochte-Holtgreven (*C. A.* **31**, 2096[3]). The second predissocn. of S_2 starting with the 18–0 band leads to an upper limit of 3.6 e. v. for the heat of dissocn. of S_2. An anomalous intensity distribution similar to that of S_2 is found for NO if it is assumed that the ϵ absorption bands are a continuation of the γ bands. This indicates a predissocn. of NO in the upper $^2\Sigma$ state of the γ bands into normal atoms with a limit 1.3 e. v. above the dissocn. limit. The remarkable intensity distribution found by Schüler, *et al.* (*C. A.* **33**, 6153[9]) in the CuH emission band λ4280 at low pressure is due to a predissocn. into the $^2\Sigma^+$ state derived from normal $Cu(^2S)$ and normal $H(^2S)$. Such a state cannot cause the predissocn. of the level $J' = 0$ in agreement with observations. The heat of dissocn. of CuH is less than 23,325 cm.$^{-1}$ (i. e., less than 2.892 e. v.). The method previously suggested (*C. A.* **27**, 1572; **29**, 2446[7]) for the detection of maxima of potential curves is applied to AlD (AlH) and BH. From the breaking off points observed in the visible bands of these mols. it is established that their $^1\Pi$ states have potential curves with maxima. Therefore, the dissocn. energies are appreciably lower than the energies

of the observed breaking-off points, i. e., D_0(AlH) less than 24,775 cm.$^{-1}$, D_0(AlD) less than 25,010 cm.$^{-1}$, and D_0(BH) less than 28,350 cm.$^{-1}$. G. M. Petty

The absorption of iodine in some of its principal solvents. Francesco Cennamo. *Nuovo cimento* **16**, 355–9(1939).—The spectrum of I dissolved in C_6H_6, CCl_4, CS_2, $CHCl_3$, CH_3OH and acetone is detd. in the visible and ultraviolet. In solvents with no dipole moment the spectrum resembles that of I vapor. If the solvent has a dipole moment, the spectrum differs for each soln. J. B. Austin

Flame and arc spectra of some calcium and strontium salts. R. K. Asundi and B. K. Vaidya. *Nature* **145**, 224(1940).—The flame and arc spectra of $SrCl_2$ and $CaCl_2$ are usually contaminated with O: the anomalous doublet sepn. of ~600 cm.$^{-1}$ is due to this contamination. When the oxide bands are eliminated, the remaining bands can be arranged in a system with a doublet sepn. of about 260 cm.$^{-1}$, in reasonable agreement with theory. The bright continuous bands which start at 18,005 cm.$^{-1}$ in Ca and at 16,352 cm.$^{-1}$ in Sr are due to metal mols. of the van der Waals type. G. M. Petty

Change of the ultraviolet absorption spectrum of acrolein with time. A. M. Buswell, E. C. Dunlop, W. H. Rodebush and J. B. Swartz. *J. Am. Chem. Soc.* **62**, 325–8 (1940).—The change in the absorption spectrum of acrolein in H_2O and alc. solns. was detd. over a period of time. The absorption due to the carbonyl of the acrolein changes with time, and the change is slowed down in the presence of an antioxidant. A new band that appears at 2670 A. is probably due to the carbonyl of a mol. formed by the polycondensation of the acrolein, since the product described by Gilbert and Donleavey (cf. *C. A.* **32**, 7410[8]) gives the same absorption band. The effect of hydroquinone and tannic acid on the spectrum of acrolein was detd. Curves for propionaldehyde in H_2O and 50% alc. solns., for acetal in H_2O, paraldehyde in 50% alc. and aldol in 50% alc. are given. A. B. Garrett

The relation between the energy of a hydrogen bond and the frequencies of the O-H bands. Richard M. Badger. *J. Chem. Phys.* **8**, 288–90(1940); cf. *C. A.* **32**, 463[3].—A relation has previously been shown between the energy of a H bond and the shift in frequency of the O-H bands which accompanies the formation of the bond. When the shift (0–600 cm.$^{-1}$) in frequency of the third harmonic O-H band (in the region 9500–11,000 A.) which accompanies this change is plotted against bond energy (0–7500 cal.) the points for CH_2ClCH_2OH, PhOH in C_6H_6, *o*-$Cl_2C_6H_4$, H_2O and MeOH lie on a flat curve. The carboxylic acids do not lie on this curve. G. M. Petty

Vibration spectra and molecular structure. IX. Further studies of the vapors of the fatty acid series. Robert C. Herman. *J. Chem. Phys.* **8**, 252–8(1940); cf. *C. A.* **33**, 8115[6].—The monomer spectra of the vapors of PrCOOH, PrCOOD and BuCOOH were obtained from 1 to 12 μ at about 150° and pressures of 6–23 mm. The assocn. of HCOOH, HCOOD and PrCOOD was studied in the vapor phase: the bond strengths are 6.2, 6.1 and 6.9 kg.-cal./mole/bond, resp. The fact that the bond strengths for HCOOH and HCOOD agree within the exptl. error, although the detns. were made with different bands, is further evidence that the spectroscopic method is satisfactory. The lower value obtained for HCOOH compared to the vapor d. value is discussed. It is not possible to claim the existence of a simple linear relationship between the bond strength and $\Delta\nu/\nu$. Some results concerning ν(CH) absorption in the first 5 members of the fatty acid series are given. G. M. Petty

Infrared and Raman spectra of molecules. Anna Ciccone. *Nuovo cimento* **15**, 482–521(1938).—A comprehensive review of the theory of infrared and Raman spectra and of their application in investigating the structure of di- and poly-at. mols. B. C. P. A.

Spectroscopic evidence for hydrogen bonds: SH, NH and NH_2 compounds. Walter Gordy and Spencer C. Stanford. *J. Am. Chem. Soc.* **62**, 497–505(1940); cf. *C. A.* **34**, 1562[4].—Infrared-spectrum methods were used to study assocn. of mercaptans and amines with certain electron donner solvents. In ethyl-*o*-toluidine the SH band of thiophenol was virtually unaffected; in isopropyl ether and in aniline only a slight perturbation of the band occurred; in pyridine, α-picoline and dibenzylamine there was a shift of approx. 0.18 μ to the longer wave lengths, together with a broadening and a marked increase in intensity. These effects are believed to indicate H bonding between the latter solvents and thiophenol, with the SH group donating the proton. Similar but less pronounced effects were observed for butyl mercaptan, benzyl mercaptan and thioacetic acid with some of these solvents. Evidence that thiophenol is not polymerized in the liquid state was obtained when it was observed that the SH band appears in the same position in a 0.1 *M* soln. of thiophenol in benzene as it does in the pure liquid. The amines studied have basicity consts. about the same as, or lower than, that of aniline. All were found to be assocd. through H bonds except those for which steric hindrance would be expected to prevent the assocn. The absorption spectrum of the NH or NH_2 group of the unassocd. amine in dil. soln. of CCl_4 was obtained and compared with the absorption of the same group of the pure liquid or a concd. soln. when the compd. was a solid. Each of the compds. was studied in an oxygenated solvent, butyl ether, in order to detect complex formation through NH → O bonds with the ether. The results indicate that the following compds. are polymerized in the pure state and form complexes with the ether: pyrrole, diphenylamine, *o*- and *p*-toluidine, α-naphthylamine, *o*- and *m*-chloroaniline. Indole does not polymerize but it does appear to form a compd. with butyl ether. Ethyl-*o*-toluidine apparently neither polymerizes nor forms complexes; its lack of assocn. can be attributed to steric hindrance. Evidence for chelation was obtained for Me anthranilate and *o*-nitroaniline; chelation probably prevents appreciable polymerization or complex formation. The compd. α-naphthol was found to be more strongly assocd. than the NH or NH_2 compds. of similar structure. Tables of the position of the SH band of the mercaptans studied and for the minima in the transmission curves for the NH and NH_2 compds. studied are included. A. B. Garrett

The infrared absorption spectrum of methylamine. Ralph G. Owens and E. F. Barker. *J. Chem. Phys.* **8**, 229–32(1940).—The parallel type $MeNH_2$ band at 10 μ was resolved. The center is at 1045.27 cm.$^{-1}$. It closely approximates axial symmetry. The mean of the 2 largest moments of inertia is 37.43×10^{-40} g. sq. cm. The C-N distance is 1.48×10^{-8} cm. There may be a superposed perpendicular band. The 13-μ band is assigned to a motion corresponding to ν_3 in NH_3. Other bands were examd. but could not be resolved. G. M. Petty

Special transmission of glucose glass in the near infrared. Willi M. Cohn. *J. Chem. Phys.* **8**, 232–3(1940); cf. *C. A.* **32**, 2429[4].—Transmission data are given from 4400 A. to 9800 A. for 7 glucose glasses with various thermal histories. No limit of absorption was found up to 12,000 A. (the photographic limit). G. M. Petty

Effect of crystal orientation on the Raman spectrum of sodium nitrate. T. M. K. Nedungadi. *Proc. Indian Acad. Sci.* **10A**, 197–210(1939); cf. *C. A.* **33**, 4873[9].—The Raman spectrum of cryst. $NaNO_3$ was obtained at different orientations of the crystal relative to the directions of incidence and observation and different states of polarization of the incident and scattered radiations. The principal observation is that the 98 and 185 cm.$^{-1}$ lattice vibrations disappear when the lines corresponding to the internal oscillations, 720, 1065 and 1385 appear and vice versa when the incident light is polarized and the scattered light analyzed. The 2 lattice lines also disappear in the longitudinal scattering of unpolarized light incident along the optic axis. This indicates that these oscillations are in the nature of a torsional movement or tilt of the NO_3^- ions in the cryst. lattice. The strong birefringence of the crystal causes the internal oscillations to appear more strongly when the incident light vector is in the plane of the NO_3^- group than when it is perpendicular to it. The induced moment does not coincide in direction with the incident light vector for the sym. oscillation of the

NO_3^- ion excited by light vibrations in the plane of the ion. The incidence of a linear elec. oscillation probably either gives rise to elliptical polarization in the plane of the ion or the individual NO_3^- ion does not possess trigonal symmetry in its own plane. J. H. Hibben

Effect of crystal orientation on the Raman spectrum of calcite. S. Bhagavantam. *Current Sci.* **8**, 507–8(1939); cf. *C. A.* **33**, 4873[1].—A cube of calcite was cut so that its optic axis was parallel to one edge. The intensities of the Raman lines 155, 282, and 1084 were estd., both parallel and perpendicular to the direction of the incident light *OX*, with the optic axis in the *OX*, *OY* and *OZ* orientations and (separately) for light vibrating in the *OZ* and *OY* directions. The data of Nedungadi for $NaNO_3$ (preceding abstr.) are discussed, and are compared with these data. G. M. Petty

Raman spectra of some metatungstates, both crystalline and in aqueous solution. Marie Théodoresco *Compt. rend.* **210**, 297–8(1940); cf. *C. A.* **34**, 2256[1]. The Raman spectrum of Na metatungstate, $Na_2O.4WO_3.10H_2O$, prepd. as directed by Copaux (*C. A.* **3**, 2008[1]), both crystd. and in soln., and that of solid $BaO.4WO_3.nH_2O$ were detd. In all cases the spectra are characteristic; this indicates that the metatungstates are well-defined compds. differing from the neutral tungstates, and showing the presence of H_2O of crystn. in both the solid and dissolved states. C. A. Silberrad

Raman effect of symmetric difluorotetrachloroethane. Geo. Glockler and C. G. Sage. *J. Chem. Phys.* **8**, 291 (1940); cf. *C. A.* **34**, 1561[9]. The $\Delta\nu$, intensity, and mean deviation are reported for 22 Raman shifts in FCl_2CCCl_2F. G. M. Petty

Raman effect and chemical constitution. Influence of constitutive and other factors on the double bonds in organic compounds. II. Effect of the phenyl group or the carbonyl bond in esters. G. V. L. N. Murty and P. R. Seshadri. *Proc. Indian Acad. Sci.* **10A**, 307–16(1939); cf. *C. A.* **33**, 4874[7].—The Raman spectra of Ph benzoate, Ph acetate, Ph cinnamate and Me and Et benzoates were detd. in detail. The C=O frequency is 20 wave nos. $cm.^{-1}$ higher in the Ph ester than in the Me or the Et ester. The C=O frequency for the aromatic esters is lower than for the corresponding aliphatic esters. If the Ph group is not directly attached to the C of the carbonyl group but is attached through an O atom the C=O frequency is increased. These facts are explained from considerations of electrometric polarization and resonance. J. H. Hibben

Raman effect and dipole moment in relation to free rotation. XI. Raman spectra of deuterio 1,2-dibromoethanes. San-itiro Mizushima, Yonezo Morino and Akira Suzuki. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 281–5(1939); cf. *C. A.* **33**, 3222[4].—The Raman spectra of liquid and solid $1,2\text{-}C_2D_4Br_2$, $1,2\text{-}C_2H_3Br_2$ and liquid $1,2\text{-}C_2D_3HBr_2$ were detd. The totally sym. frequencies (C_{2h}) of solid *trans*-$1,2\text{-}C_2D_4Br_2$ were 188, 605, 907, 991, 1154 and 2183 wave nos. $cm.^{-1}$ and for $1,2\text{-}C_2H_4Br_2$ were 190, 660, 1053, 1255, 1440 and 2972 $cm.^{-1}$. The large increase in the no. of lines in the liquid as compared with the solid state is explained by supposing the mean internal configuration shows a considerable deviation from the transposition owing to the intermol. rotation around the C–C axis, the spectra from the liquid being that of the solid superposed on frequencies which are different from the trans form. Another explanation of the increase in the no. of lines is in the supposition that there is an oscillatory motion of small amplitude about the trans position which would alter the selection rules for the mol. sym. C_{2h} so that the normal vibrations antisym. to the center of the trans form are allowed in the Raman effect, the lines corresponding to the sym. vibrations remaining practically unchanged. Conclusion: there is no free rotation, in its literal meaning, around the C—C axis, the mol. tending to assume its most stable configuration. J. H. Hibben

Occurrence of overtone lines in the Raman effect. S. Bhagavantam. *Proc. Indian Acad. Sci.* **10A**, 224–8 (1939).—The intensities of fundamental and overtone frequencies of harmonic and anharmonic diatomic oscillators are calcd. Results are given for HCl, HBr, H_2, N_2 and O_2 which show that the intensity of the fundamental may be 150–500 times that of the overtone. J. H. H.

Continuous wings occurring in the Raman effect. K. Bapayya. *Proc. Indian Acad. Sci.* **10A**, 253–61(1939).—The intensity of rotational Raman scattering in gases is directly related to the optical anisotropy of the mol., but with liquids other phys. properties, such as viscosity and dipole assocn., as well as optical anisotropy influence the characteristics of the continuous wings scattered in the liquid state. The wing intensity of C_6H_6 was found to be large in comparison to cyclohexane even when the horizontal components, alone, of the scattered radiation are compared and in spite of the fact that the mols. have similar structures and moments of inertia. The intensity of the cyclohexane wing is, in turn, greater than that of AcOH although its optical anisotropy is less. C_6H_6 and AcOH exhibit the same depolarization factor and possess nearly the same optical anisotropy but AcOH exhibits a wing much less intense than C_6H_6. No sepd. maxima in the liquid wing were observed at 30 or 200°. There is an increase in the central portion of the wing with increased temp. The origin of the wing is considered to be in the rotary or oscillatory motion that occurs in solids but less sharply quantized, i. e., hindered rotation. J. H. H.

Dipolar absorption bands of capryl alcohol. Leo Cavallaro. *Ricerca sci.* **8**, I, 424–6(1937); *Chem. Zentr.* **1938**, I, 1309; cf. *C. A.* **31**, 8377[6]; **32**, 3268[1].—With capryl alc. the absorption maxima for the frequencies 5, 10.5, 18 and 26 m. lie between about + 30 and about −10°, the temp. decreasing with increasing frequency. Upon slowly cooling to about −43° the alc. is transformed into a white, glassy mass; at the same time the absorption bands for the frequencies investigated suddenly disappear. When the temp. is raised again, the glassy condition can be preserved up to about −35°; there the absorption suddenly appears again, but with 2 maxima. Obviously, the phenomenon is the result of viscosity changes and mol. assocn. M. G. Moore

Dipolar absorption bands of cetyl alcohol. Leo Cavallaro. *Ricerca sci.* **8**, II, 124–6(1937); *Chem. Zentr.* **1938**, I, 4309; cf. preceding abstract.—The dipolar absorption bands of cetyl alc. were detd. in the temp. interval 50–100° for the wave lengths 5, 10.5, 18 and 26 m. The shorter the wave length the more the absorption max. is displaced toward the higher temp. By use of the formula of Debye, the mol. radius of cetyl alc. was calcd. to be 9 A. If the absorption bands of cetyl alc. are compared with those of other alcs. it is apparent that with increasing no. of C atoms the absorption max. is displaced toward higher temp. M. G. Moore

The influence of quasi-crystalline structure on the molecular rotation and relaxation in dipole liquids. F. Fischer and G. Klages. *Physik. Z.* **40**, 721–8(1939).—The dispersions between 150 and 10 cm. are detd. for pure *acetone*, *PhCl*, *$PhNO_2$*, *o-$C_6H_4Cl_2$*, *decyl chloride*, *lauryl chloride* and *cetyl chloride* and are compared with data for dil. solns. in C_6H_{6}. The liquids with normal dipole interaction follow the Debye theory, but the alcs. deviate from it. J. B. Austin

The proportionality of the luminescence of zinc sulfide phosphors to [the] irradiation at low intensities. J. H. Gisolf and F. A. Kröger. *Physica* **6**, 1101–11(1939) (in English).—ZnS-Cu phosphors show a green and a blue band, ZnS-Ag show the same, with different relative intensities, probably due to Cu as an impurity, while ZnS-Mn show blue and yellow bands. Several expts. show that the relative intensity of these pairs of bands depends on the intensity of the radiation. An explanation is given based on known properties of phosphors. G. W. King

Dielectric losses of irradiated zinc sulfide phosphors. J. H. Gisolf. *Physica* **6**, 918–28(1939) (in English).—The dielectric losses of ZnS films in alternating fields varying from 1 to 15,000 kc. under the influence of radiation varying in wave length from 2500 to 5000 A. were measured. There was no loss in the region of the absorption bands of Mn ion, but at other wave lengths there was always some dielec. loss, showing that in the absorption of

light an electron is excited to a conducting energy level. When this electron drops back to its original level light is evolved as fluorescence; but when it drops back via metastable levels, phosphorescence results. The latter occurs in the tail absorption, more than 3400 A. G. W. King

The decay of alkali-halide phosphors activated by thallium. V. Antonov-Romanovskiĭ and G. Kochergin. *Compt. rend. acad. sci. U. R. S. S.* **24**, 430-2(1939)(in English).—A hyperbolic decay curve indicates a bimol. mechanism. An exponential decay curves does not necessarily mean a unimol. reaction. S. Bradford Stone

The catalytic oxidation of hydrogen on platinum. A search for chemiluminescence and ionization. R. Potvin and C. Ouellet. *J. Phys. Chem.* **44**, 235-46(1940).—A search for the ultraviolet chemiluminescence accompanying the reaction $H_2 + {}^1/_2 O_2 \rightarrow H_2O$ on a Pt filament at a total pressure of 10 mm. between 80° and 170° has shown that such radiation must be smaller than 1 photon per 10^8 mols. reacting. Neg. electricity emitted from the filament during reaction is attributed to a localized thermionic effect. Emission of pos. electricity seems to be independent of the reaction and sets in at about 310°. P. H. Emmett

New methods in spectroscopy. Geo. R. Harrison. *Science* **91**, 225-8(1940). E. H.

Investigation of the structure of the fluorescence spectrum of aniline vapor. A. Vartanyan. *J. Phys.* (U. S. S. R.) **1**, 213-28(1939).—See *C. A.* **33**, 4523[2]. A. D.

Fluorescence and absorption spectra of complex molecules. D. Blokhintsev. *J. Phys.* (U. S. S. R.) **1**, 117-24 (1939). See *C. A.* **33**, 7664[9]. A. D.

The spark as the source of light for spectral analysis. I. Spectra of various regions of spark. S. M. Raĭskiĭ. *J. Tech. Phys.* (U. S. S. R.) **9**, 1719-26(1939).—The spark between flat electrodes of Mg, Zn, Hg, Al, etc., has the shape of a spindle; near the electrodes it is 0.1-0.2 mm. and in the middle between the electrodes 3-4 mm. wide. Consequently the density of the energy is higher near the electrodes than in the middle. In agreement with this, spectral lines requiring high energies of excitation are emitted near, and those requiring less energy, far from the electrodes. J. J. Bikerman

Excitation of active nitrogen. Harold P. Knauss and Allen E. Murray. *Rev. Sci. Instruments* **11**, 78(1940).—The vacuum in a tube was reduced to obtain the green NO-O_2 discharge with a 700-v.-output transformer. The air discharge was continued for 6-8 hrs. This procedure was repeated several times to condition the tube. A strong yellow Lewis-Rayleigh afterglow then was produced with a flow of dry tank N. The favorable condition of the tube was retained indefinitely unless air was admitted. H. G. Bowlus

Mean life of electronically activated nitrogen. René Audubert and Charles Racz. *Compt. rend.* **210**, 217-19 (1940); cf. *C. A.* **34**, 30[2].—Slow thermolysis, or electrolysis of aq. solns., of azides (e. g., NaN_3, KN_3, HN_3) is accompanied by ultraviolet radiation, which is independent of the cation, and is due to deactivation of the N. By electrolysis of an aq. soln. of NaN_3 with a special arrangement by which the circuit is periodically opened and closed the av. life of the activated N is detd. as $2.5 \pm 0.2 \times 10^{-3}$ sec. This N therefore passes through a metastable state, which spectral analysis shows to be different from that of Strutt's active N. C. A. Silberrad

Magneto-optical anomaly of ordinary and heavy water. Atuyosi Okazaki. *Proc. Phys.-Math. Soc. Japan* **21**, 753-8(1939)(in English); cf. *C. A.* **31**, 4875[6].—The earlier calcns. are extended to cover ultraviolet wave lengths and higher temps. A. O. Allen

Magnetic anisotropy of diphenyldiacetylene. Kathleen Lonsdale. *Nature* **145**, 148-9(1940).—The principal crystal susceptibilities of PhC:C.C:CPh are: χ_1, -93.8×10^{-6} (± 0.5); χ_2, -188.0×10^{-6}; χ_3, -109.6×10^{-6}; ψ, $-88.5°$; $\chi_{av.}$, -130.5×10^{-6}. The principal susceptibilities of a single mol.: K_L, -109.4; K_M, -75.3; K_N, -206.7×10^{-6}. By comparison with the corresponding values for tolane, it is shown that there is an abnormal increase of susceptibility along the C chain axis, indicating a concn. of electron d. normal to that axis. G. M. Petty

Hydrogen isotope exchange reaction. J. O. Halford. *J. Chem. Phys.* **8**, 243-7(1940).—Math. The possibility of deriving the equil. consts. for the higher D substitutions from the isotope exchange coeff. is examd.; calcns. on the NH_3 and CH_4 reactions with water are used. If the expt. is carried to solns. at equil. with water contg. as much as 25% D_2O and if the error in a single measurement does not exceed 1.0% the second const. is detd. to within 10% of the correct value. An equation is developed for the relation between the equil. const. for the first substitution and the exchange factor at higher D fractions; it is assumed that each successive substitution of D for H produces the same frequency shift. The evaluation of frequency shifts from exchange data is considered. G. M. Petty

Scattering screens. S. Pieńkowski and I. Mrozowska. *Ann. acad. sci. tech. Varsovie* **2**, 15-70(1935); *Chem. Zentr.* **1938, I**, 4358.—After a discussion of the work of others, a series of expts. is reported on the reflection of diffuse light by plates of various materials. An effort was made to discover a surface giving off diffuse radiation which would meet the requirements of an international standard. Frosted opal glass, frosted opal glass covered with a layer of gypsum, porcelain, gypsum and white filter paper were examd. Measurements were made for angles of incidence of 0, 15, 35 and 55° and curves constructed showing the relation of the relative brilliance to the angle of observation and the angle of incidence. Opal glasses of different manuf. were compared and the influence of the thickness and the material with which the frosted glass had been treated was detd. The surface conditions of frosted opal glasses treated with carborundum of varying grain size (0.1 mm. to less than 0.01 mm.) or frosted by chem. methods were investigated and their optical behavior was measured. From a consideration of all measurements and the tech. questions of production, permanence and reproducibility it is concluded that chemically frosted opal glass of at least 3 mm. thickness offers the most satisfactory surface for the supplying of diffuse light for photometric measurements. Curves and tables of all measurements are given. M. G. M.

Photochemical oxidation of hydrogen. I. A. B. Nalbandyan. *Acta Physicochim. U. R. S. S.* **11**, 453-74 (1939)(in English).—The velocity of the photochem. oxidation of H at pressures of 1-50 mm. irradiated by light of 1300-1750 A. is given by $w = (\pi J/\beta)^{1}/_{4} d^{2} (1 - e^{-k_0 l}) [1 - (-i)^{1}/_{2} apd) (J_1(ix)/J_0(ix))]$, where J = intensity of illumination, β = probability of chain d = diam. and l = length of reaction vessel, k = absorption coeff. for O, $a = \sqrt{(3\beta_{11}/4\lambda_0 q)}$, $x = apd$, q = no. of collisions undergone by O_1 before reaction with H, and $J_0(ix)$, $J_1(ix)$ are Bessel functions of 0 and 1st order. The mechanism of the zone formation process is: $O_2 + h\nu = O' + O$; $O + H_2 + M = H_2O + M$ (M = any mol.); $O + O_2 + O_2 = O_3 + O_2$; O + wall = ${}^1/_2 O_2$. The probability of the reaction $O + H$ is 10^{-6}. The quantum yield is 2 mols. of $H_2O + O_3$ per quantum absorbed. N. believes that no chains are formed, but that both excited and normal atoms act as active centers. F. H. Rathmann

Reactions of free radicals with organic compounds containing atoms with unshared electron pairs. Francis O. Rice, W. D. Walters and P. M. Ruoff. *J. Chem. Phys.* **8**, 259-62(1940); cf. *C. A.* **32**, 7405[6].—An exptl. test for the reaction Me + MeOEt → Me_2O + Et was made by decompg. MeOEt both alone and in the presence of MeN:NMe and examg. the products for Me_2O. None was detected, and if this reaction occurs at all it is to only a small extent. A similar test for the reaction Me + $PrNH_2$ → $MeNH_2$ + Pr was made by decompg. pure $PrNH_2$ in a flowing system, with a neg. result. The products formed in the promoted decompn. of Me_2O were essentially the same as those formed in the normal decompn. G. M. P.

Free radicals in the pyrolysis of acetaldehyde. Milton

Burton, John E. Ricci and Thomas W. Davis *J. Am. Chem. Soc.* **62**, 265–7(1940).—The method of Leighton and Mortensen (*C. A.* **30**, 3327[4]) employing Rd-Pb in Paneth mirrors has been modified and used to detect the existence of free radicals in the pyrolysis of AcH at 500°. Data are given on the transport of Rd-Pb in the pyrolysis of AcH. A. B. Garrett

Splitting the CONH linkage by means of ultraviolet light. D. C. Carpenter. *J. Am. Chem. Soc.* **62**, 289–91 (1940).—The observations of Rideal and Mitchell with respect to the photolysis of stearic anilide (*C. A.* **31**, 7760[2]) were confirmed. Benzylstearylamine and β-phenylethylstearylamine undergo photolysis when irradiated as monolayers with light of λ = 2483 – 2537 A. It is expected that peptides and proteins having side chains bearing chromophore groups will behave similarly; the CONH groups adjacent to the side chain should undergo photolysis and the light-absorbing amino acid should be liberated from the peptide or the protein mol. The mol. areas of stearic anilide, benzylstearylamine, and β-phenylethylstearylamine were measured. A. B. G.

The quenching of mercury resonance radiation by ethylene. E. W. R. Steacie. *Can. J. Research* **18**, B, 44–6(1940).—An investigation at λ2537 shows a quenching cross section of 48 ± 5 × 10^{-16} sq. cm. J. W. S.

Cadmium-photosensitized reactions of ethylene. E. W. R. Steacie and Roger Potvin. *Can. J. Research* **18**, B, 47–54(1940); cf. *C. A.* **33**, 483[1], 8502[5]. The Cd-photosensitized reactions of C_2H_4 and of C_2H_4-H mixts. were studied. With C_2H_4 alone the quantum yield of the reaction is very low, viz., about 0.01. With C_2H_4-H mixts. the quantum yield is about 0.5–0.7 depending on the conditions. The products of the reaction are CH_4, C_2H_6, C_2H_8, C_4H_{10}, C_3H_6 and higher hydrocarbons. The mechanism of the reaction is discussed and compared with that of the Hg-photosensitized reaction. Conclusion: The main steps of the reaction in the presence of H are $H + C_2H_4 \rightarrow C_2H_5$; $H + C_2H_5 \rightarrow C_2H_6$; $H + C_2H_5 \rightarrow 2CH_3$; together with radical recombination reactions and reactions of the type $C_2H_3 + C_2H_5 \rightarrow C_4H_9$. J. W. S.

Photoreactions sensitized by the halogens. J. W. T. Spinks. *Chem. Rev.* **26**, 129–39(1940). All of the halogen-sensitized photoreactions known can be explained by chem. mechanisms involving halogen atoms. L. K.

Photosensitive surfaces for television tubes. Joseph T. Tykocmer, Jakob Kunz and Lloyd P. Garner (to Board of Trustees of the Univ. of Ill.). U. S. 2,185,531, Jan. 2. A photosensitive surface is formed by bubbling molecular H through molten alkali metal, expanding the resulting vapor and applying the expanded vapor to a suitable cathode surface. Apparatus is described.

4—ELECTROCHEMISTRY

COLIN G. FINK

New method for the manufacture of magnesium metal. Freitag. *Oberflächentech.* **17**, 190(1940).—While Mg is now almost entirely produced by electrolysis of fused $MgCl_2$, a new process just developed is said to be much cheaper. It consists in reducing MgO by coke to metal in an elec furnace at 2000°. Mg metal vapor and CO are formed; this mixt. is quenched by cold H_2, and Mg metal is pptd. as dust with impurities of C and MgO. The ppt. is distd. *in vacuo* and the Mg collected under hydrocarbon oils in which it solidifies in grains of 10–20 mm. diam. consisting of Mg metal of 99.97% purity. No information as to energy consumption and details of the process is given (cf. Landis, *C. A.* **31**, 5277[4]). M. Hartenheim

Calcium manufacture. V. P. Mashovets. *Tsvetnye Metal.* **1938**, No. 6, 92–8; *Khim. Referat. Zhur.* **2**, No. 5, 82(1939).—The main disadvantage in the production of Ca is its soly. in the electrolyte. This soly. is overcome by the use of a contact cathode. In the small single-cathode baths (using water cooling) the cathodic c. d. is high and the cell amperage small. Owing to the large amt. of energy consumed (up to 60 kw.-hr./kg. Ca) and to the difficulties encountered in handling, the cost of Ca production increases. It is proposed to construct a multicathodic bath without any artificial cooling which would permit the production of 1 kg. Ca per 26.5 kw.-hr. consumed. W. R. Henn

Reduction of silicon and aluminum. M. S. Maksimenko. *Metallurg* **14**, No. 4–5, 26–34(1939).—In the electrothermal production of Al-Si alloys, SiO_2 is first reduced to Si or SiC and the Al_2O_3 is subsequently reduced by SiC. The amt. of coke in the charge must be carefully regulated, as an excess will cause the formation of Al_4C_3 in the lower part of the reaction zone, while insufficient coke will cause the formation of mullite slag which is refractory and difficultly tapped. The presence of a small amt. of Fe in the charge accelerates the formation of SiC and thus promotes the reduction of Al_2O_3. A 2-electrode single-phase furnace is better than a single-electrode furnace with bottom return owing to decreased heat loss, greater elec efficiency and longer life of the C bottom. H. W. Rathmann

Overcoming thermocouple errors in high-temperature induction furnaces. Frank Day, Jr., and Hurd W. Safford. *Ind. Eng. Chem.* **32**, 445–6(1940).—In a graphite-core tube-type induction furnace temp. readings obtained with a thermocouple were erratic and lower with the induced current on than when it was off. The effect is perhaps due to thermionic emission from the graphite core. Enclosure of the thermocouple in a grounded shield of Pt foil completely eliminated the difficulty. Cf. the following abstr. W. B. Keighton

Electrical phenomena in a high-temperature laboratory furnace. H. E. Stauss. *Ind. Eng. Chem.* **32**, 446 (1940).—A d. c. potential is set up in resistance coils under test at 1200–1400° within an alundum tube furnace with Pt alloy resistor. The effect is present with either a. c. or d. c. in the furnace resistor and is shown to be caused

by thermionic emission from the alundum. These stray currents are eliminated by a grounded shield of Pt wire wound on a ceramic tube between the furnace tube and resistance coil. The shield is connected to the resistance coil and to the ground side of the furnace winding.
W. B. Keighton

Method of preparation of anodes made of iron with surface layer of magnetic oxide. II. Oxidation by gaseous oxygen. Naoto Kameyama and Atusi Naka. *J. Soc. Chem. The recovery of metals from wastes. Richard Springer. *Z. Metall- u. Schmuckwaren-Fabrik. Verchrom.* **19**, No. 7, 11-12; No. 9, 11-12(1938); *Chem. Zentr.* **1938**, II, 3151.—The electrolytic recovery has not been given sufficient attention. The electrolytic recovery of Ni, Cu, brass, Cr, Zn and Ag is critically discussed.
M. G. Moore

Cottrell dust precipitation during the treatment of electrolytic slimes. A. I. Levin. *Tsvetnye Metall.* **14**, No. 1, 63-73(1939); *Khim. Referat. Zhur.* **2**, No. 5, 80-1(1939).—In working up Se-contg. slimes from Cu electrolysis, SeO_2 must be removed to prevent corrosion of the elec. dust precipitators. The construction and operation of the dust collectors and of the app. for pptn. of SeO_2 from soln. at the Kyshtym electrolytic plant are described.
W. R. Henn

The electrochemical behavior of selenium. Giuseppe Sella. *Ricerca sci.* **10**, 1143-4(1939).—A polished Pt electrode immersed in a 0.5-mol. soln. of H_2SeO_3 acquires coatings of allotropic forms of Se in this succession: red pulverulent (0-50°), dark red-brown (50-60°), lead gray (60-70°), metallic gray (70-100°). The latter itself has 2 allotropic modifications differing in elec. cond. with a transition point at 140°. At 25° the reversible potential referred to the H electrode is +0.655 v. The definite transition point from the pulverulent to the vitreous-metallic form is about 62°. The calcd. entropy of the electrolytic reduction of H_2SeO_3 is 70.
O. W. Willcox

Electrodeposition of nickel from nickel chloride solutions. W. A. Wesley and J. W. Carey. *Products Finishing* **4**, No. 6, 18-20, 22, 24, 26-7, 30, 32, 34(1940); cf. *C. A.* **34**, 2260[6].—A discussion of the phys. properties of deposits (hardness and tensile tests, and Erichsen ductility), protective value (ferricyanide tests, salt spray, atm. exposure and porosity), characteristics of the plating soln. (tank voltage, cond. and cathode efficiency), advantages of the chloride bath (low tank voltage, ease of buffing, heavy deposits, ease of control, freedom from pitting, cathode efficiency and the heating of soln.) and the disadvantages of the chloride bath. It is quite possible that further study of electrolytes contg. both sulfate and chloride will disclose an intermediate compn. which would be less corrosive than the chloride bath and productive of more ductile deposits, yet would retain to a large extent the advantages of the sulfate-free electrolyte. The results of tests indicate that the modern trend to the use of higher chloride contents in the Watts-type soln. is sound and should be encouraged.
Leopold Scheflan

Medical supervision of nickel-chromium plating shops. Bek and Fournier. *Méd. d'usine* **1**, No. 6, 8-17(1938); *Chimie & industrie* **42**, 269.—A discussion of the precautions which should be taken in connection with each of the dangerous operations effected in this industry.
A. Papineau-Couture

The electrolytic preparation of copper-zinc-nickel alloy. N. A. Izgaryshev and Kh. M. Ravikiovich. *J. Gen. Chem.* (U. S. S. R.) **9**, 1443-55(1939).—The electrolytic prepn. of the Cu-Zn-Ni alloy by the Faust and Montillon method (*C. A.* **28**, 3003[7] and **29**, 2858[1]) was not applicable for the theoretical investigation of the cathode process nor for the applied purposes because of poor reproducibility of the exptl. data and instability of the cyanide solns. The deposition simultaneously of 2 or 3 metals was carried out in the presence of colloids. The added substances caused the approximation of the potential of metal depositions. This method of "approximation of the deposition potential" was used in the simultaneous deposition of Cu-Zn, Cu-Ni, Ni-Zn and Cu-Zn-Ni from their sulfate solns. in the presence of 1% H_3BO_3 and with the addn. of gum arabic or cresolsulfonic acid. The Cu-Zn-Ni alloy prepd. by this method was of high durability and of a fine-grain structure. All polarization curves of the above systems can be represented by the equation $\Delta\epsilon = AD^n$, where $\Delta\epsilon$ is the difference between the potential at certain c. d., D, and the equil. potential. A is a const. corresponding to the initial conditions of the process and n is a const.
A. A. Podgorny

Electrolytic processes for metal finishing. E. J. Dobbs. *J. Inst. Production Engrs.* **18**, 343-9(1939).—A brief review of anodic oxidation of Al, chromating of Mg and its alloys, and hard Cr-plating of steel tools and surfaces subject to abrasion. Mg alloys are also finished by immersion in a soln. of H_2SeO_3 or an acid soln. of a selenite. The reddish brown film of Se makes an excellent base for painting. $ZnCrO_4$ in a tung-oil paint, followed by a cellulose coating pigmented with Al leaf, is recommended.
M. W. Schwarz

Metal coloring, theory and practice. III. Joseph B. Kushner. *Products Finishing* **4**, No. 6, 46-8, 50(1940); cf. *C. A.* **34**, 1954[3].—Tested formulas for precious-metal plating solns. are given including Rh, Pt, Pd and Ag. All the common finishes with the white precious metals are described.
Leopold Scheflan

The theory of the potential and the technical practice of electrodeposition. I. The general problem and the cases of uniform flow. Charles Kasper. *Trans. Electrochem. Soc.* **77**, 11 pp. (preprint)(1940).—There is no field of technology which so involves and so well illustrates the theory of potential as that of electrodeposition. A detailed exposition and discussion are presented of the flow of current through the electrolyte when the electrodes are: (*a*) parallel planes, (*b*) concentric cylinders, and (*c*) concentric spheres.
C. G. F.

Effect of alternating current on the cell Pb|H_2SO_4|Pt. Julian Kamecki and Mieczysław Wierzbicki. *Roczniki Chem.* **19**, 249-58(1939).—The strength of the current in the cell Pb|aq. H_2SO_4|Pt rises, while time elapsing before discharge of the cell falls, as the concn. of the H_2SO_4 is raised from 0.2 to 5 *N*. During and after passage of an a. c. a d. c. arises; this is due to depassivation of the Pb, by removal of the $PbSO_4$ coating, in the case of 0.2-0.5 *N* H_2SO_4, and to a rectifying effect in that of 5 *N* H_2SO_4.
B. C. P. A.

The polishing, plating and anodizing of the aluminum

light alloys. E. E. Halls. *Metallurgia* **21**, 123–6(1940). —Some practical pointers are given. J. L. Gregg

The mercury cathode in metallurgical analysis. A. E. Pavlish and John D. Sullivan. *Metals & Alloys* **11**, 56–9 (1940).—The effects of kinds of acids, different degrees of acidity and of varying concns. of Fe on the operation of the Hg cathode in electrolytic sepn. of elements were investigated. The results showed that for pptn. of Fe in H_2SO_4 soln. the normality of the acid may be as high as 10. The over-all rate of Fe removal is greatest when the concn. is between 10 and 30 g. per l. With a soln. contg. 1 g. Fe, electrolysis is complete in about 45 min.; with 5 g. in about 3 hrs. Solns. of $HClO_4$, H_3PO_4 and H_2SO_4–H_3PO_4 can be used as electrolytes. A simple air-agitator, water-leaching method for regeneration of the Hg is described. 6 references. I. Hartmann

Electrolytic processes in magnetic fields. N. P. Fedot'ev and A. I. Evstyukhin. *Trudy LKKhTI* **1939**, No. 7, 32–41; *Khim. Referat. Zhur.* 2, No. 5, 83–4(1939). —The action of the magnetic field on the electrolytic cell causes a transfer of ions (Holl's effect). To verify this supposition expts. were performed with an acid $CuSO_4$ soln. with Cu electrodes. The direction of the magnetic field was perpendicular to the liquid layer and to the direction of the current. A 7000-gauss strength in the zone of the greatly concd. magnetic field caused a 12.1% deviation of the equipotential lines with respect to the potential gradients. The current lines are deviated by the magnetic field and are perpendicular to the equipotential lines. This was verified by the distribution of the metal on the cathode to which the magnetic field was directed. A considerable overweight of the metal was observed in the region of the cathode with denser current lines as compared with regions with rarefied current lines. An intensive mixing of the liquid was observed in all electrolysis expts. with the magnetic field. Two circular motions of the liquid were formed if the magnetic field was directed to the center of the cell. When the magnetic field was directed to one of the electrodes, a mixing was observed which was in the form of a circular motion of the liquid along the whole length of the bath. The influence of the magnetic field on the elec. cond. of the system is of interest. When an electromagnet was included in the system the total potential of the cell first decreased, then increased, but did not reach the initial value without the magnetic field. The observed phenomena can hardly be of practical importance, since a very strong magnetic field is required to obtain small deviations of the current lines. W. R. Henn

Role of the forces between the particles in electrodepositions and other phenomena. H. C. Hamaker and E. J. W. Verwey. *Trans. Faraday Soc.* **36**, 180–5(1940) —The mech. aspects of deposition by electrophoresis for suspensions in org. media are discussed. A voltage of 50 to 100 v. applied to electrodes immersed in a suspension of $BaCO_3$ in C_2H_5OH caused the cathode to coat rapidly with a layer of $BaCO_3$. Details are discussed. V. R. D.

Electro-organic chemical preparations. II. Sherlock Swann, Jr. *Trans. Electrochem. Soc.* **77**, 40 pp. (preprint) (1940); cf. *C. A.* **30**, 3727[9]. —This review is an extension of an earlier list of syntheses which includes literature published before Jan., 1940. C. G. F.

The overvoltage of hydrogen in liquid ammonia. V. A. Pleskov. *Acta Physicochim. U. R. S. S.* **11**, 305–14 (1939).—Measurements were made in liquid ammonia in the presence of 0.1 *N* NH_4Cl at −50° and at c. d. of 10^{-7} – 10^{-2} amp./cm.^{2}. For solid Hg Δ V increases quickly to 0.2 and then slowly up to 0.8–0.9 v. above its value in an aq. soln., but, due to diffusion of the NH_4-amalgam film, exact measurements are impossible. For a Ni electrode, the overvoltage obeys Tafel's equation with b = 0.09 as given by Volmer's theory; Δ V above that in aq. soln. is only 0.1–0.2 v. For a Pb electrode Δ V = approx. 1.1–1.2 v. For the electrochem. series in liquid NH_3, Ni should probably be placed directly above H. F. H. R.

Electrolysis by discharge in gases. Fr. Fichter and Kurt Kestenholz. *Helv. Chim. Acta* **23**, 209–11(1940).—By means of elec. discharge from electrodes above a soln. contg. KH_2PO_4, KOH, KF and K_2CrO_4, the authors produced $K_4P_2O_8$ (tetrapotassium peroxydiphosphate). The process was rather inefficient. The app. is described. William E. Vaughan

Electrochemical potential and the Volta effect. O. Scarpa. *Nuovo Cimento* **16**, 281–93(1939); cf. *C. A.* **34**, 1257[2].—The potentials for the elements should be corrected for the contact potential of the metals comprising the circuit used in making the measurement. When such a correction is made the electrode potentials have values significantly different from those now accepted, although the order of increasing potential is about the same. The contact potential between Pt and hydrogenated Pt, obtained indirectly, is of the order of 0.5 v. J. B. A.

Cover for storage-battery cells. Henry J. Hikkie (to B. F. Goodrich Co.). Can. 387,276, Mar. 5, 1940. Structural details.

Electric resistors. Gerald L. Pearson (to Bell Telephone Laboratories, Inc.). U. S. 2,184,847, Dec. 26. A method of joining a metallic conductor such as a Pt wire to a body of B to form an elec. resistor involves bringing the conductor into contact with the B body, applying heat at the point of contact to raise the temp. thereat to a value substantially less than the m. p. of the conductor to form at the point a joint comprising a compd. of B and of the metal of the conductor, and controlling the temp. at the point of contact to det. the size of the joint formed and the resistance of the element.

High-voltage rectifier or inverter. Joseph Slepian (to Westinghouse Elec. & Mfg. Co.). U. S. 2,186,215, Jan. 9. Various structural details of an app. having a Hg cathode.

Selenium rectifier films. Samuel Wein (to B-L Electric Mfg. Co.). U. S. 2,186,085, Jan. 9. For producing a Se coating on a cond. plate such as one of Fe, it is sprayed with a soln. of selenious acid and the latter is reduced to Se with a reducing agent.

Rectifier tube for alternating voltages of a peak value of at least 250 v. Johannes Bruijnes, Daniel M. Dunker and Johannes G. W. Mulder (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,184,709, Dec. 26. Various details of a tube contg. Hg and an inert gas such as Ne.

Electrical contacts. James M. Kelly (to Westinghouse Elec. & Mfg. Co.). U. S. 2,186,245, Jan. 9. Contacts such as those of make and break devices for heavy currents are formed contg. 45–75% of refractory metal powders such as Mo and 55–25% of a bonding alloy contg. Ag together with Cu 1–10 and Sb 1–10%.

Gas-blast switches. The British Thomson-Houston Co. Ltd. Brit. 509,000, July 10, 1939. Addn. to 501,241 (*C. A.* **33**, 6481[4]). An extinguishing chamber for a self-generating gas-blast switch as claimed in 501,241 has an addn. of an oxidizing substance, e. g., MgO_2, to prevent tracking upon the extinguishing process. Cf. *C. A.* **33**, 7891[4].

Contacts for electric switches. Robert A. Miller and Harry C. Rubly (to Standard Telephones and Cables Ltd.). Brit. 508,991, July 10, 1939. A switching device comprising stationary and movable contacts is made of metallic materials having substantially the same electrothermal but unlike phys. characteristics that are so matched that substantially no thermocouple effect is produced when the contacts are brought into engagement. One material may be pure Cu and the other hardened Be Cu. 1

Electric condenser. V. T. Renne. Russ. 55,955, Oct. 31, 1939. The dielec. of a condenser is made from paper impregnated with chlorinated naphthalene preliminarily fused with 2–5% benzylcellulose. 2

Electrolytic condenser. Arnold Deutschmann (to Tobe Deutschmann Corp.). U. S. 2,184,686, Dec. 26. Various structural details.

Cell for electrolysis of aqueous solutions of alkali metal chlorides. S. N. Shoikhet and A. A. Fomenko. Russ. 55,931, Oct. 31, 1939. Construction details. 3

Apparatus for treating surfaces by electrolysis. V. F. Kurto. Russ. 55,905, Oct. 31, 1939. Construction details.

Smooth surfaces on metals. V. F. Kurto. Russ. 56,009, Nov. 30, 1939. Cavities in the objects to be treated are filled with a dielectric and the surfaces are then etched anodically to eliminate projections.

Removing coatings such as gold from copper composition bases such as transmitter electrode cups. Sumner R. Mason (to Western Electric Co.). U. S. 2,185,858, Jan. 2. The coated base is electrolyzed in an aq. soln. contg. sufficient H_2SO_4 to give a sp. gr. of 1.65, thus ptg. the coating metal. App. is described. 4

Anodic oxidation of aluminum, copper or copper-aluminum alloys. A. S. Tsitrinovich and V. D. Ivanov. Russ. 55,966, Oct. 31, 1939. The metals are oxidized in H_3BO_3 soln. with the addition of $Na_2B_4O_7$ or NaOH.

Carbides of boron, silicon and titanium. A. V. Tikhonov. Russ. 55,959, Oct. 31, 1939. The carbides are formed by heating the elements with C in a high-frequency furnace.

Purification of aluminate solutions. V. M. Mukhachev. Russ. 52,201, Nov. 30, 1937. Aluminate solns. are purified by electrolysis with permeable cathodes and anodes.

Introducing iron alloys into steel in electric furnaces. V. D. Oshchepkov, V. I. Butin, P. A. Peretrukhin and N. D. Zaboya. Russ. 56,092, Nov. 30, 1939. The melting of iron alloys is accelerated by thickening the slag before their introduction to such an extent as to float the Fe alloys on the surface of the slag when exposed to the direct action of the elec. arc. 6

High-frequency smelting furnace. Fritz Hartmann (to Kohle- und Eisenforschung G. m. b. H.). U. S. 2,184,741, Dec. 26. Various structural, elec. and operative details, including an automatic elec. cut out operative on excessive rise in temp. of cooling water use.

Vapor electric converter. Ernest G. Bangratz (to Westinghouse Elec. & Mfg. Co.). U. S. 2,186,189, Jan. 9. A make-alive electrode for a converter having a pool-type cathode comprising a body of graphite, the body having a very hard semiconduction surface secured by treating the graphite with B at high temp., the semiconducting surface being in contact with the pool-type cathode during normal operation of the converter, a stem secured to the graphite body, a collar on the stem adjacent the graphite body and an insulating covering on the stem. Cf. *C. A.* **33**, 9161[2].

Apparatus for the electric sublimation of phosphorus and the preparation of phosphorous anhydride. P. F. Zhdan. Russ. 55,830, Oct. 31, 1939. Construction details.

Cathodes for electron-emitting devices. Ernest A. Lederer (to Radio Corp. of America). U. S. 2,185,410, Jan. 2. A cathode comprises a core consisting essentially of a metal (such as W-Ni alloy) that reacts with a Ba-O compd., Be (to reduce the compd. and liberate free Ba at a temp. below the m. p. of the core), an O compd. of Ba and Be (such as Ba beryllate 5%) dispersed throughout the core, a matrix capable of holding the metallic Ba (comprising an adherent alk. earth coating such as CaO, BaO, SrO or MgO) on the core, such coating being cryst., chemically inert to the Ba and having a m. p. above the activating temp. of the core.

Arc-lamp cathodes. Jean Parisot (to Le Carbone-Lorraine). U. S. 2,185,679, Jan. 2. See Brit. 509,291 (*C. A.* **34**, 5343).

Electric discharge devices. Ernest E. Charlton (to General Elec. Co.). U. S. 2,185,832, Jan. 2. A method of prepg. elec. discharge devices having metal parts inclosed within an envelope consists in inductively heating the metal parts to remov. the gases therefrom and later vaporizing a getter previously affixed to one of the metal parts in such a position as to be substantially without the field of inductive effect employed in previously heating the metal parts whereby the metal parts may be first inductively heated and the getter may be later inductively vaporized by the effect of a subsequently applied inductive field displaced from the first inductive field, removing the residual gas from the envelope and sealing the envelope. 5

Electric incandescent lamp. Willem Elenbaas, Eduard G. Dorgelo and Hendricus J. Lemmens (to General Elec. Co.). U. S. 2,185,025, Dec. 26. Various details of a filament lamp contg. a fixed gas such as mixed A and N under superatm. pressure together with Hg. 6

5—PHOTOGRAPHY

E. R. BULLOCK

Photography goes forward- a review of a decade of progress. Glenn E. Matthews. *Am. Ann. Phot.* **54**, 7–26(1940); cf. *C. A.* **33**, 5303[3].

New developments of the diazotype process and screen reflectography in documentation. P. C. P. Huysers. *F. I. D. Commun.* **6**, 20–3(1939). The history of the diazotype and also of reflectography (reflex process) is given. The latter culminates in the Retocee process (*C. A.* **29**, 5366[7]; **30**, 976[9]) which uses a line screen and diazotype paper. R. P. Loveland 8

New photographic tracing processes. Heinz Falta. *Gebrauchsfotografie* **46**, 249–53(1939).—The nature of diazotype papers and their historical development are reviewed in some detail. Modern papers are of 2 types: those developed by NH_3 vapor ("dry process") and those developed by momentary immersion in aq. solns. of the couplers ("damp process"). The first type contains both the diazo compd. and an azo coupling component, and the 2nd type contains only the diazo compd.; both yield a positive as only those areas develop which were exposed to light. These methods possess the following advantages over those using Ag halides: lower cost, rapid processing (no fixing or washing and only momentary drying) and bright-light manipulation. The disadvantages lie in the low speed and more expensive app. required. The diazo layer is coated on transparent cellulose and on film base as well as on paper. The new processes permit the copying of opaque materials and intensification of originals. R. W. Henn 9

Ozaphane and its application to microcopy. J. Holloway. *F. I. D. Commun.* **6**, 40–2(1939).—A nontech. description of the ozaphane process is given in which the dye image is incorporated in a single substratum such as cellophane or cellulose acetate. Arguments for the superior stability of cellophane over cellulose acetate are given. R. P. Loveland

Application of microfilm to photography by luminescence. L. de Saint-Rat. *F. I. D. Commun.* **6**, 42–5(1939).—The principles of photography by luminescence to decipher faded or altered documents are discussed. R. P. L.

Report on DK-20. Walter Petermann. *Photofreund* **19**, 264(1939).—A modified formula for the Eastman

Kodak DK-20 fine-grain developer is: H_2O 400 cc., $Na_3PO_4.12H_2O$ 0.25 g., metol (elon) 2.5 g., Na_2SO_3 50 g., KSCN 0.5 g., KBr 0.5 g. and H_2O to 500 cc. To prep. the developer, either add the Na_3PO_4 with the other chemicals as given in the formula or dissolve it in boiled H_2O before adding and then allow the soln. to stand and pour off from the ppt. The use of the Na_3PO_4 avoids possible formation of Ca scum on the negatives and permits more rapid soln. of the developing agent, so that cool H_2O can be used for mixing. L. E. Muehler

Theory of the Schwarzschild effect. Kienle. *Z. wiss. Phot.* **37**, 282–3(1938). A. Narath. *Ibid.* 283.—Reply. Cf. *C. A.* **33**, 8129[4]. B. C. P. A.

Constant development in the tank. Helmuth Dehio. *Veröffentl. wiss. Zentral-Lab. phot. Abt. AGFA* **6**, 214–24 (1939).—Through proper replenishment the original activity of a developer soln. can be maintained essentially const. over long periods of use. Negatives of uniform quality and degree of development can be assured and a marked economy in materials and labor costs can be effected by controlled replenishment. The method of replenishment is illustrated for 2 Agfa developers, the Roentgen Rapid developer and the Final Fine Grain Tank developer. Accompanying curves depict the behavior of contrast and d. upon exhaustion with and without proper replenishment. Tables are included showing the av. developing times for normal and high contrasts at various temps. between 15° and 25°. H. A. Miller

Direct toning with sodium sulfide (hyposelenosulfate mixture). Martin Götz. *Phot. Chronik* **47**, 5(1940).—Direct toning of developed prints in about 2 min. is accomplished by the use of the following soln.: $Na_2S_2O_3$ 5-H_2O 100 g., Na sulfide 20 g., selenosulfate soln. 10 cc. and H_2O 1000 cc. The selenosulfate soln. is prepd. by dissolving 20 g. of Na_2SO_3 in 100 cc. of hot H_2O, adding 3 g. of Se and heating until the Se is dissolved. One l. of the direct toner tones about 80 postcards before becoming too slow. Another addn. of 10 cc. of the selenosulfate soln. acts as a replenisher. L. E. Muehler

Advances in motion-picture negative film emulsions. Andreas Schilling. *Veroffentl. wiss. Zentral-Lab. phot. Abt. AGFA* **6**, 65–75(1939).—Two new motion-picture neg. materials for the general trade and industry, Agfa Super Pan film and Agfa Ultra Rapid film, are described. A cross section is given of an improved Fino Pan film. The different layers of this film from the underside up are: (1) an antistatic backing, (2) a support, (3) a blue-gray dye layer, (4) a subbing, (5) an emulsion undercoat, (6) an emulsion topcoat and (7) a protective gelatin layer. Tables are given showing the relative development rates and speed of the film compared with Pankine-H and DIN, Weston and General Electric material ratings. There are illustrations showing grain sizes and spectrograms and tables giving speeds to primary colors and factors with various filters. Spectrogram absorption curves and the discussion that follows indicate that the Ultra Rapid is similar to Pankine-H in color sensitivity, while the Super Pan and Fino Pan are less red-sensitive. The Super Pan, Ultra Rapid and Fino Pan have, resp., 2, 4 and 0.75 times the total speed of Pankine-H. R. M. Corbin

Spectral sensitivity of photographic layers. I. John Eggert and Martin Biltz. *Veroffentl. wiss. Zentral-Lab. phot. Abt. AGFA* **6**, 23–36(1939); cf. *C. A.* **32**, 8927[6]. —Measurements were made of the spectral sensitivity distribution of a no. of emulsions for print-out and developing-out images. A pure AgBr emulsion showed a sharp break in the curve at about 500 mμ; an explanation is given for this based on a consideration of the impurity centers in the crystals. A series of emulsions of varying AgI contents was made and studied; it was found that the wave length at which the break in the distribution curve took place progresses toward longer wave lengths as the AgI content increases. Ripening of an emulsion was found to have no effect on the curve. For optically sensitized emulsions, it was found that the break in the distribution curve depends on the dye used, and that the effect of the dye on print-out sensitivity is small. The effect of concn. of sensitizing dye on sensitivity was studied and the results of measurements are given. The mechanism of the sensitizing process is discussed. II. John Eggert and Friedrich G. Kleinschrod. *Ibid.* 37–45.—A brief discussion of recent latent image theories is given. A series of emulsions was made, and the spectral distribution of sensitivity of each was measured. Ripening was found to have little effect on NH_3 emulsions as regards the wave length at which the break in the distribution curve occurs; at long wave lengths (greater than 600 mμ) the sensitivity curves were found to vary with the ripening times. Peptized and diffusion emulsions were similar to NH_3 and non-NH_3 emulsions in sensitivity-wave length reactions. The effect of various gelatins was studied. The break at 500 mμ is independent of the gelatin used, but the shape of the sensitivity curve at longer wave lengths varies with the gelatin. J. A. Leermakers

Investigations in atomic physics by means of the photographic layer. Erwin Schopper. *Veroffentl. wiss. Zentral-Lab. phot. Abt. AGFA* **6**, 170–8(1939); cf. *C. A.* **34**, 9513.—The possibilities of employing a photographic method to record single particles by means of their tracks in the photographic emulsion are demonstrated. The method proves to be especially advantageous for the investigation of rare at. processes. The particles comprising cosmic rays can be identified and nuclear processes of formerly unknown high-energy exchanges can be observed. C. H. Evans

Working with Isopan-Ultra film. Heinrich Freytag. *Phot. Chronik* **47**, 20–1(1940).—To obtain max. speed with Agfa Isopan-Ultra film, the following 2-bath developer is suggested: *A*: metol 10 g., Na_2SO_3 100 g. and H_2O 1 l., *B*: borax 50 g. and H_2O 1 l. Develop in *A* until the image is just visible (usually 60–100 sec.), then immerse in *B* for 30 sec. Return the film to the 1st soln. for about 2 min. and finally to the 2nd for 30 sec. L. E. Muehler

Statistical investigations of the interrelations of Callier quotient, graininess and limit of enlargement. John Eggert and Alfred Kuster. *Veroffentl. wiss. Zentral-Lab phot. Abt. AGFA* **6**, 186–97(1939); cf. *C. A.* **31**, 6123[3]. —E. and K. show statistically that values of graininess for neg. materials detd. subjectively from enlargements of negatives are paralleled by the *K* values detd. by phys. measurements on the negatives ($K = 100 \log_{10} Q$ where Q is the Callier quotient at a diffuse d. of 0.50). It is further shown that the limits of satisfactory enlargement of 2 neg. materials are inversely proportional to their *K* values, detd. as above. C. H. Evans

Graininess of photographic papers for exposure to quanta of high energy. John Eggert and Erwin Schopper. *Veroffentl. wiss. Zentral-Lab. phot. Abt. AGFA* **6**, 159–69 (1939); cf. *C. A.* **33**, 2829[9].—For films exposed to x-rays it is observed that graininess increases with increasing quantum energy of the exposing radiation. By the method of the Callier quotients, it is found experimentally that an increase of av. grain diam. occurs. A simultaneous deviation of grain distribution from the purely statistical distribution is probable. The phenomenon of increasing graininess is explained upon the assumption that grains in the neighborhood of the absorbing grain are influenced by secondary particles arising from the absorption of a quantum of high energy. The effect also occurs upon exposure to high-speed electrons. The resulting "electron halo" limits the resolving power of the emulsion. For x-rays, the lack of sharpness may be directly visible. C. H. Evans

The duplication of documents, etc., by photographic methods. A. de Waele. *F. I. D. Commun.* **6**, 15–16 (1939).—Various methods of reproducing printed matter to be used in an office are briefly reviewed. R. P. L.

Carbon tissue. F. Heigl. *Deut. Drucker* **45**, 623–5 (1939).—A general description of the manuf., sensitization and use of photogravure tissue. A. Murray

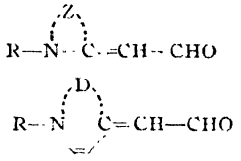
Color photography. Eastman A. Weaver (to Comstock & Wescott, Inc.). U. S. 2,186,053, Jan. 9. A method of reproducing a color picture by superimposing records of several color aspects involving deficient coloring matter properly absorbing light transmitted by the taking filter of its color aspect, but improperly absorbing light which should only be absorbed by coloring matter for a second aspect, comprises making a photographic record of the first color aspect of the picture, the record and the first aspect being of opposite sign, printing from the first record in register with the color picture a colored corrective record combined from the record and the second aspect, and then printing a corrected picture with the color picture and the corrective record in registered combination. U. S. 2,186,054 relates to a method of color photography on Ag halide emulsions which involves exposing a sensitized layer of emulsion to one color aspect, while leaving in the layer an amt. of unexposed Ag halide forming a corresponding positive, and emulsion in addn. to that amt., developing the layer into a negative, removing the Ag from the developed negative, exposing the Ag halide from one side in register through a positive of another color aspect, the latter exposure being incomplete, and the emulsion therefore correctively affected by the light absorption of the positive and again developing the layer whereby a corrected positive of the first color aspect is formed. Cf. C. A. **34**, 2271[2].



Subtractive color film. Gerd Heymer (to Agfa Ansco Corp.). U. S. 2,186,070, Jan. 9. A process of producing fade-outs in a subtractive 3-color motion picture film contg. 3 differently colored dye images, in which the fade-outs are produced by decreasing the exposure of successive frames of the color image record, involves uniformly applying to each of the frames an addnl. dye complementary in light-absorption to the color tending to predominate and in such quantity as to give a neutral black with the color.

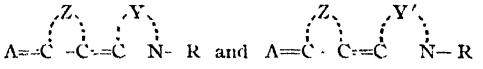
Color photographic pictures. Wilhelm Schneider (to Agfa Ansco Corp.). U. S. 2,186,045, Jan. 9. Pictures in color are produced by use of a photographic Ag halide emulsion contg. a binding agent such as gelatin and α-indolinone or a substituted α-indolinone such as 6-amino-α-indolinone contg. a group capable of making the compd. fast to diffusion in the binding agent.

Photographic emulsions containing dyes. Rene Stevens. U. S. 2,185,798, Jan. 2. Photographic emulsions of special sensitivities comprise a Ag halide emulsion with addn. of a dye of the general formula S.CR′R″.NR.NXY: CCH:(CHCH)$_n$C.Z.NX′, where R is a phenyl, naphthyl or the monohalogen-substituted phenyl, while R′ is H or alkyl, R″, X and X′ are alkyls, Y is an anion and Z represents the nonmetallic atoms necessary to complete a heterocyclic 5- or 6-membered heterocyclic nucleus, *n* being a member of the group constituted by the integers including 0.

Nondiffusing photographic dyes and color formers. Wilhelm Schneider and Alfred Fröhlich (to General Aniline & Film Corp.). Can. 387,215, Mar. 5, 1940. Dyes or intermediates are treated with anhydrides of polybasic org. acids, substituted by radicals that prevent diffusion of the reaction product. In one of several examples, 1-amino-5-naphthol is treated with dodecylcyclohexylpyrotartaric anhydride, added in alk. soln. with Na_2CO_3 to a Ag halide emulsion and cast as a layer. After exposure, development with a color-forming developer produces a blue-dye picture.

Polymethine dyes suitable for sensitizing photographic emulsions. Grafton H. Keyes and Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,185,343, Jan. 2. By the reaction of a monoacylated aminoacetic acid such as aceturic acid, hippuric acid or naphthoylaminoacetic acid (suitably in the presence of a water-binding agent such as Ac_2O or the like) with a formylmethylene compd. of one of the formulas

where D represents the nonmetallic atoms necessary to complete a heterocyclic nucleus, such as a pyridine or a quinoline nucleus for example, Z represents the nonmetallic atoms necessary to complete a heterocyclic nucleus, such as a 5-membered or 6-membered heterocyclic nucleus for example, and R represents an aliphatic radical, i. e., an alkyl group, sensitizing dyes are produced of one of the formulas



and

Numerous examples with details are given.

Merocyanine dyes. Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,185,182, Jan. 2. Numerous examples are given of the production of dyes having one of the formulas

where A represents a bivalent O or S atom, R represents an alkyl group, Y represents the nonmetallic atoms necessary to complete a heterocyclic nucleus selected from the group consisting of azole, azoline, indolenine, pyridine and quinoline nuclei, Y′ represents the nonmetallic atoms necessary to complete a heterocyclic nucleus selected from the group consisting of pyridine and quinoline nuclei and Z represents the nonmetallic atoms necessary to complete a heterocyclic nucleus selected from the group consisting of 5-membered heterocyclic nuclei contg. a nuclear S atom, 5-membered heterocyclic nuclei contg. a nuclear N atom and 6-membered heterocyclic nuclei contg. a nuclear N atom. Various of these dyes are suitable for *prepg. sensitized photographic emulsions*, and they may be prepd. by treating a cyclammonium quaternary salt contg. a reactive group, such as a halogen atom, particularly an I atom, a substituted-mercapto group or an aryloxy group, for example, in the α or γ position, i. e., one of the so-called reactive positions, with a heterocyclic org. compd. contg. a nuclear methylene group adjacent to a nuclear carbonyl group, such as an oxocarbonyl or thiocarbonyl group (suitably in the presence of an org. base such as triethylamine or of various other basic condensing agents and with heating of the reactants).

Direct-printing light-sensitive films. E. A. Bukatin. Russ. 55,985, Oct. 31, 1939. Ag bromide or chloride emulsion on any carrier is sensitized by immersion in, or coating with, aq. alc. soln. of salts of phenylhydrazine.

Obtaining desired intensities in photographic reproductions. Kenneth L. Henderson. U. S. 2,186,138, Jan. 9. A method of making a photographic reproduction

of a desired range of intensities from a photographic negative comprises exposing a photosensitive strip to the subject to be photographed, simultaneously photographing on the strip along with the image of the subject, an image of an approx. white object exposed through a graduated scale located in adjacent substantial parallel relation with the strip, the scale comprising tone areas progressively varying from approx. transparency to approx. opaqueness, developing the photographed strip to provide a negative, printing a positive from the negative, and developing the positive, the printing of the positive being effected so that a given tone in the printed image of the scale on the positive bears a definite intensity relation to a corresponding tone in a previously made print. App. is described.

Reaction between ammonia and $SeO_2.2HCl$ and $SeO_2.2HBr$. Julius Jackson and G. B. L. Smith. *J. Am. Chem. Soc.* **62**, 543–4 (1940).—The products of the reaction of $SeO_2.2HCl$ or $SeO_2.2HBr$ with NH_3 are $(NH_4)_2SeO_3$ and the corresponding halide and NH_4 dihaloselenite, $(NH_4)_2SeO_3X_2$. The formation of the NH_4 salts of dichloroselenious acid and dibromoselenious acid shows that these acids are present in $SeO_2.2HCl$ and $SeO_2.2HBr$; however, the formation of the NH_4 salts of selenious acid and of HX indicates that no single structure can be assigned to $SeO_2.2HCl$ or $SeO_2.2HBr$. It is suggested that these materials comprise an equil. mixture (dynamic isomers) of the type: $H_2SeO_2X_2 \rightleftarrows SeOXH_2O.X$. The H_2O in the $SeOXH_2O.X$ is replaced by NH_3, forming $SeONH_2X$; the H_2O so liberated causes hydrolysis of the $SeO_2X_2^-$ ion yielding HX and H_2SeO_3. A. B. Garrett

Selenium oxychloro compounds of pyridine, pyridinium chloride and related substances. Julius Jackson and G. B. L. Smith. *J. Am. Chem. Soc.* **62**, 544–6 (1940).—$SeOCl_2$ forms two series of compds. with pyridine, quinoline and isoquinoline of the general formulas $RSeOCl_2$ and R_2SeOCl_2. The quinoline and isoquinoline compds. of the type R_2SeOCl_2 are not decomposed at 61°, whereas the similar pyridine compd. decomposes to the "monopyridinate" at 61° in 167 hours. Isoquinoline has the greatest tendency to combine in a 2–1 ratio; pyridine has the least. The compds. of the type $RSeOCl_2$ are all stable at 61°. The findings agree with the thesis that $SeOCl_2$ is the parent solvent of a system of compds. (cf. *C. A.* **32**, 8975⁴), and that pyridine and related substances act as bases in $SeOCl_2$. A. B. Garrett

Formation of hydrogen peroxide by the explosive method. M. V. Polyakov, I. E. Neimark and F. G. Maksimuk. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **7**, No. 1, 21–8 (in Russian, 29; in English, 29) (1937); cf. *C. A.* **33**, 4895⁴, 8095³, 8482⁷. Results are reported on the yields of H_2O_2 by exploding mixts. of $2H_2 + O_2$ under pressures of 80–130 mm. Hg and wall temps. ranging from −40 to −180°. At 100 and 130 mm. the yield of peroxide increases noticeably as the temp. of the walls is decreased to −120°, but any further drop in temp. causes a very small increase in the yield. The yields at 100 mm. were higher than at 130 mm. At 80 mm. the yield below −120° increases considerably down to −180°. The resp. yields of peroxide at −180° at 80, 100 and 130 mm. were 2.28, 1.3 and 0.62%. Within the interval of −40 to −120° the yield and wall temp. are expressed by $K = \log(a T^{3/2})$, where a is yield and T is abs. temp.; K is about 3. Mechanism of peroxide formation is discussed. B. Z. Kamich

Data on the chemical composition of gold cupride. M. P. Lozhechkin. *Compt. rend. acad. sci. U. R. S. S.* **24**, 451–4 (1939) (in English).—Native gold cupride is mixed with gold argentide. The compn. of gold cupride can vary from Cu_2Au_3 to Cu_3Au. S. Bradford Stone

The chemical nature of precipitated basic magnesium carbonate. Jack R. I. Hepburn. *J. Chem. Soc.* **1940**, 96–9.—Pptns. carried out over a concn. range of 1.0–0.05 *M*, by the addn. of $MgSO_4$ solns. to Na_2CO_3 solns., lead to the conclusion that the CO_2 content of the ppt. is a continuous function of the amt. of CO_2 remaining in the soln. It is therefore possible that freshly pptd. basic Mg carbonate is produced by the adsorption of HCO_3 ions by $Mg(OH)_2$. H. C. Thomas

Peculiar isomerism in synthetic and mineral inorganic compounds. A. Quartaroli and O. Beltori. *Rend. seminar. facolta sci. univ. Cagliari* **7**, 111–42 (1937); *Chem. Zentr.* **1938**, II, 3380–1.—The amorphous $Ca_3(HPO_4)_2$ obtained as a voluminous ppt. from H_3PO_4 and $Ca(OH)_2$ dissolves in H_3PO_4 with the formation of $Ca(H_2PO_4)_2$. When allowed to stand at ordinary temps., compact, cryst. $Ca_3(HPO_4)_2$ seps. from this soln. In cryst. $Ca_3(HPO_4)_2$ the 2 Ca atoms are equiv. and are displaced by acids simultaneously (sym. formula I); in the amorphous salt the Ca atoms can be displaced one after the other (asym. formula II). The chem. symmetry is shown by the morphological form with the smaller vol. and cryst. character. There are 4 possibilities (formulas III–VI) for the triphosphate.

$$\{HPO_4\}_2Ca_2 \text{ (I)} \quad \{(HPO_4)_2Ca\}Ca \text{ (II)} \quad \{PO_4\}_2^{(1,2,3)}Ca_3 \text{ (III)}$$

$$\left\{\left[(PO_4)_2Ca\right]^{(1)}_{Ca}\right\}^{(2)}_{Ca}\Big\}^{(3)} \text{ (IV)} \quad \{(PO_4)_2Ca\}^{(2,3)}Ca_2 \text{ (V)}$$

$$\{(PO_4)_2Ca_2\}^{(1,2)}_{Ca} \text{ (VI)}$$

The indexes indicate the order of displacement. Several indexes within the same brackets indicate that the Ca atoms designated are displaced simultaneously. When treated with acids, III should give neither diphosphate nor monophosphate but only H_3PO_4 directly and should not be hydrolyzable, since no diphosphate can be formed. IV could give all 3 successively; V only dicalcium phosphate and H_3PO_4; and VI only monocalcium phosphate and H_3PO_4. IV and V are hydrolyzable but VI is not. The behavior of pptd. tricalcium phosphate and of bone meal corresponds to formula VI; that of phosphorite and apatite to a mixt. of III and VI. A study of the phosphates of Ba and of Li indicated a similar type of isomerism. In general, the sym. form was produced at higher temps. It was shown experimentally that synthetic and natural $MgCO_3$ have different solubilities. The former, which is amorphous and voluminous and readily converted into $Mg(HCO_3)_2$ by weak acids, corresponds to the formula $\{(CO_3)_2Mg\}Mg$. Magnesite, which is less sol. than the synthetic salt and is scarcely attacked by weak acids, corresponds to the formula $\{CO_3\}_2Mg_2$. Magnesite cannot be converted into $Mg(HCO_3)_2$. According to the formulas suggested, the reaction between H_2S and synthetic $MgCO_3$ should take place in accordance with the equation: $2\,MgCO_3 + H_2S = Mg(HCO_3)_2 + MgS$ and that with magnesite in accordance with the equation: $MgCO_3 + H_2S = MgS + H_2O + CO_2$. Detn. of CO_2 in the reaction products verified both equations. The behavior of various carbonates is discussed. Ca and Mg give predominantly the asym. forms (only magnesite is

sym.) which can be converted into bicarbonate; this tendency decreases with Zn, Co and Ni. Those metals which give bicarbonates readily also give hydrosulfides readily. The behavior of NiS and CoS is explained by the assumption that {S_2Ni|Ni and {S_2Co|Co are first formed. These are sol. in acids. In alk. soln. S_2Ni_2 and S_2Co_2 are formed directly. These are attacked by acids with difficulty, not because H_2S reacts with greater difficulty than HS but because the sym. pairs Ni_2 and Co_2 must be displaced simultaneously. ZnS behaves in a similar manner. The possibility of the existence of isomers of CO_2 and $COCl_2$, as evidenced by their manner of formation, is discussed. CO + O should give the asym. CO_2 while C + O_2 should give the sym. mol. CO + Cl_2 should give a product differing from that obtained from CCl_2 + O, since in the 2nd product the Cl atoms have the same type of bond as in CCl_4 while in the first product the C- Cl bond is weakened by the presence of the =C=O bond. An explanation of some of the properties of water is offered (with reservations), in which it is assumed that water is a mixt. of the sym. form H_2O and the asym. form (HO)H. By analogy with the above examples, the asym. form possesses a greater vol. than the sym. form; raising the temp. favors the formation of the sym. form. Since with falling temp. the amt. of the more voluminous, asym. form increases, it is possible that at a certain point an increase in vol. should take place in spite of the cooling. At 0° a soln. of H_2O in (HO)H is present. With increase in pressure the amt. of H_2O increases. After the eutectic is passed a soln. of (HO)H in H_2O is present from which H_2O crystallizes out. In this way the lowering of the f. p. with pressure is explained as well as the fact that at high pressures an ice having a d. > 1 can be obtained. The compressibility coeff. of water decreases from 0 to 50°. This is attributed to the progressively smaller role played by the conversion of (HO)H into H_2O by pressure (with reduction in vol.) with increasing temp. as a result of the decreasing concn. of (HO)H. The relation between reaction velocity and temp. is given empirically by the formula $v_1 = v_0 + a^{t_1 - t_0}$, where in general $a \approx 2$. In reactions in which water takes part a is often definitely greater between 0 and 50°. In the reaction COS + H_2O = CO_2 + H_2S, a is 3.68 (15 40°). In the blackening of $Cu(OH)_2$ $a > 7$; this is due to the fact that between 0 and 50° the amt. of H_2O and therefore the amt. of the active H_2O mols. (2 H + O) increases. Expts with $Cu(OH)_2$ are described in detail. M. G. Moore

Reactions of chromates at high temperatures. X. Decomposition of mixtures of calcium chromate with sodium carbonate and with ferric oxide. D. S. Datar and S. K. K. Jatkar. *J. Indian Inst. Sci.* **22A**, 225–36(1939); cf. *C. A.* **33**, 6190⁶.– A 2:1 mixt. of $CaCrO_4$ and Na_2CO_3 when heated decomposes with evolution of CO_2 to form the basic chromate, $4Na_2O.8CaO.8CrO_3$, which on heating further decomposes in stages corresponding to 25%, 33⅓% and 10% decompn. of the chromate to form, resp., $4Na_2O.8CaO.6CrO_3.Cr_2O_3$, $3Na_2O.6CaO.4CrO_3.Cr_2O_3$ and $5Na_2O.10CaO.6CrO_3.2Cr_2O_3$. Measurements of the characteristic decompn. pressures of the mixed chromates indicate respective heats of decompn. of 14.9, 43.6, 24.4 and 37.4 cal. per mole of O. Evidence is found for a basic chromium chromate of Fe. **XI. Structure of chromium chromates.** *Ibid.* 287–307.—Structures are suggested for 23 compds. of general formula $aCr_2O_3.bCrO_3$, formed by thermal decompn. of CrO_3 and of chromates of Ca, Sr and Ba. These structures contain the units —Cr(O)(O)Cr—O— and —Cr(=O)(=O)—. CaO, SrO and BaO may be added where Cr is doubly linked to O. **XII. Magnetic properties of chromium chromates.** *Ibid.* 309–15.—Magnetic susceptibilities calcd. on the basis of the formulas in XI for the oxides of Cr agree fairly well with reported measurements. Av. valencies of Cr calcd. from the magnetic susceptibilities also agree with expt. Discrepancies are attributed to traces of magnetic impurities and to polymerization factors. Wm. E. Trout, Jr.

The molecular volume of water in certain complex compounds. Petru G. Spacu. *Bull. sect. sci. acad. roumaine* **21**, 35–7(1938–39).—From the observed ds. of the complexes, *trans*-[Co en_2Cl_2]Cl, *cis*-[Co en_2Cl_2]Cl, *cis*-[Co $en_2(H_2O)Cl]Cl_2$ and *cis*-[Co $en_2(H_2O)_2]Cl_3$, where en = ethylenediamine, the mol. vols. are, resp., 157.16, 166.38, 180.56 and 194.76. The increases in vol. on addn. of the 1st and 2nd mols. of H_2O are, resp., 14.18 and 14.20; these vols. are approx. the vol. of H_2O at zero abs. The vols. at zero abs. of the components, Co = 6.5, Cl = 16.3, en = 55, yield a value of 165.4 for [Co en_2Cl_2]Cl, which corresponds within 0.6% to the observed vol. of the cis but not to that of the trans complex. L. E. Steiner

Ferritartrates. Eliane Poulenc-Ferrand. *Compt. rend.* **210**, 299–301(1940).—To equal amts. (10 cc.) of *M* $FeCl_3$ and *M* $C_4H_6O_6$ (H_2T) varying amts. (*x* cc.) of *M* Na_2CO_3 were added. If *x* is less than 10 cc. no ppt. occurs; if *x* = 10–20 an insol. ocher-colored ppt. (I); with *x* = 35 partial re-soln. occurs followed by deposition of a brick-red solid (II). Analysis shows that I is $H_4[Fe_4T_3(OH)_4]$, and II a salt thereof. The Na_4, Na_3H and Na_2H_2 salts were prepd. as were also the corresponding K salts. I and its salts are insol. in EtOH and Et_2O. Soly. in H_2O increases from I (insol.) to the neutral salt (very sol.); salts of K are less sol., but more stable than those of Na; I decomposes above 58°, the Na_4 salt above 90°. All are sensitive to light. The Na_4 and K_4 salts alone are cryst., forming brick-red needles, several mm. long. No other complexes resulted from 10 cc. *M* $FeCl_3$ + 10 cc. Na_2CO_3 or K_2CO_3 + *x M* H_2T, or by using 0.1 *M* solns. in place of *M*. Cf. Franke, *C. A.* **25**, 5145, and Pariselle, *et al.*, *C. A.* **28**, 2678⁹. C. A. Silberrad

Inner complex salts of the 8-hydroxyquinoline-5-sulfonic acid. Jacob Molland. *J. Am. Chem. Soc.* **62**, 541–2(1940).—The salts formed in the reaction of $Fe_2(SO_4)_3$ and $CuSO_4$ with 8-hydroxyquinoline-5-sulfonic acid were studied by a spectrophotometric method. Tables of extinction coeffs. are given. The compn. of the salts corresponds to the formulas $(C_9H_6O_4NS)_3Fe$ and $(C_9H_6O_4NS)_2Cu$. A. B. Garrett

Magnetochemical investigations. XXXV. Heavy-metal complexes of the phthalocyanines. Heinz Senff and Wilhelm Klemm. *J. prakt. Chem.* **154**, 73–81(1939); cf. *C. A.* **33**, 6102⁶.—Magnetic susceptibilities of phthalocyanines, purified by sublimation in a high vacuum, are ($\chi_a \times 10^6$): $CoC_{32}H_{16}N_8$, 20°, 2.9; −183°, 9.8; $FeC_{32}H_{16}N_8$, 20°, 10.5; −183°, 32; $MnC_{32}H_{16}N_8$, 20°, 15; −78°, approx. 21; −183°, 61; $VOC_{32}H_{16}N_8$, 20°, 1.6; −183°, 6.4. From a comparison of the exptl. mol. susceptibilities with those calcd. for normal and penetration types of complexes, it was found that neither Ni, Co, Fe nor Mn phthalocyanine represents a single type of complex, but possibly they represent types in resonance with one another. With $VOC_{32}H_{16}N_8$ the calcd. values of susceptibility for normal and penetration types of complex are identical and throw no light on the actual state of the substance; the metal in this compd. is quadrivalent. Samples of the Fe phthalocyanine were extd. with pyridine and quinoline, resp., for several hrs.; after removal of most of the solvent by distn., crystals sepd.; these were washed with alc. and dried *in vacuo*. $C_{32}H_{16}N_8Fe.2C_5H_5N$ and $C_{32}H_{16}N_8Fe.xC_9H_7N$ are both diamagnetic, the former having a magnetic susceptibility at room temp. of χ_a = −0.30 × 10^{-6}. George Ayers

Oxidation of complex compounds of platinum with hydrogen peroxide. A. V. Babaeva. *Compt. rend. acad. sci. U. R. S. S.* **24**, 145–8(1939)(in English).—A study of the reaction of complex electrolytes of bivalent Pt ($K_2[PtCl_4]$, $K_2[Pt(NO_2)_4]$, $[Pt(NH_3)_4]Cl_2$, $[Pt(NH_3)_4](NO_3)_2$) with H_2O_2 disclosed the formation of dihydroxo compds. of quadrivalent Pt and some addnl. compds. $K_2[PtCl_4(OH_2)]$ (I) could be obtained only by strict control of temp. and H_2O_2 concn. Oxidation of $K_2[PtCl_4]$ led to formation of I, $KH[PtCl_3(OH)_4]$, $K_2[PtCl_6]$ and $K_2[PtCl_3(OH)_2H_2O]$. Oxidation of $K_2[Pt(NO_2)_4]$ led to formation of $K_2[Pt(NO_2)_4(OH)_2]$, $KH[Pt(NO_2)_3OH]$ and

$K_2[Pt(NO_3)_4(OH)_2]$. Oxidation of the Alexander base $[(NH_2OH)_4Pt](OH)_2$ gave the hexahydroxo acid $H_2[Pt(OH)_6]$. 4 references. A. H. Krappe

7—ANALYTICAL CHEMISTRY

W. T. HALL

Qualitative analysis. I, II. A system to include some of the rarer elements. J. E. Clennell. *Mining Mag.* **62**, 19–26, 81 8(1940).—The outlined scheme includes W, Tl, Mo, Ti, U, Ce, Th, V and Li but does not include Be, Zr, Ta, Cb, precious metals or rare earths and little attention is paid to methods for handling minerals that are difficult to attack. Group I contains the usual Pb, Hg and Ag together with Tl and W. The TlCl is dissolved in hot water together with $PbCl_2$ from which it is sepd. by pptg. the Pb as $PbSO_4$ and detected by the formation of yellow TlI, black Tl_2S and by the flame test. WO_3 is dissolved from the ppt. together with AgCl by the usual treatment with NH_3 and identified by the test with Zn + HCl and by the formation of a white ppt. with cinchonine-HCl. Group I may also contain Sb, Sn, Bi, Mo, Ti, Ba and Sr under some circumstances although these elements belong to other groups. Sb, Sn, Bi and Ti are carried down as a result of hydrolysis, for the most part. Ba and Sr may be present in the sample as insol sulfates. Group II includes Hg, Pb, Bi, Cu, Cd, (Tl), As, Sb, Sn and Mo. The usual sepn. into 2 subgroups is made with alk. solus. contg. sulfide. The analysis of the Cu group follows conventional lines except that the effect of Tl in the higher state is considered. Alternate procedures are given for detecting As, Sb and Sn but no new test is described. The Mo is detected by the blue color that usually results upon evapg. with HCl + HNO_3 and by the test with KCNS + $SnCl_2$. Provision is also made for pptg. Mo as $PbMoO_4$. Group III contains Fe, Al, Cr, Ti, U, Ce, Th and possibly Tl and V. The detection of Zr, Hf, Be, Ta, Cb, Yt, etc., which also belongs in this group, is not considered. The analysis proceeds conventionally except for the following points: (1) The group is not pptd. as a whole by NH_4OH + $(NH_4)_2S$ at the start but the older method of pptg. one part of the group with an excess of NH_3 and considerable NH_4Cl is recommended. (2) The first ppt. is dissolved in HCl and treated with oxalic acid to ppt. Ce and Th. These elements are both detected by H_2O_2 tests after treatment with strong $(NH_4)_2C_2O_4$ to dissolve the oxalate of Th. (3) Ti is sepd. from Fe by pptg. the latter as FeS from ammoniacal soln. contg. tartrate. (4) The $K_4Fe(CN)_6$ test for UO_2^{++} is made after the soln. contg. Fe, Al, etc., is heated with strong $(NH_4)_2CO_3$ soln. Groups IV and V contain no new test except that after the Ba, Sr and Ca are pptd. as carbonates, one portion of the filtrate is boiled with NaOH till all NH_4^+ salt is decompd. and the Mg pptd. as $Mg(OH)_2$ and then in the filtrate the $LiPO_4$ is pptd. by adding Na_2HPO_4 and the $LiPO_4$ is proved sol in dil. AcOH. Flame tests alone are relied upon for the identification of Na and K. A skilled, practical chemist will undoubtedly get useful results from this scheme of analysis, which is much simpler than other schemes that have been proposed. W. T. H.

The spectrograph in quantitative analysis. Wm. C. Lee. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 102–7 (1940).—A review of work done since 1933 by the Physics department of the Univ. of Michigan, in cooperation with the department of internal medicine, of the Medical School and with certain industrial plants. Assay for platinum metals in ore concentrates. John Scath and F. E. Beamish. *Ind. Eng. Chem., Anal. Ed.* **12**, 169–71(1940).—The Pt metals are quite commonly assocd. with minerals contg. considerable Ni, Cu and Fe sulfides and in attempts to effect mech. concn. of the Pt metals, a considerable accumulation of these base metals results. In the dry assay considerable difficulty is encountered in collecting all the precious metals in a Pb button after a single fusion, it is hard to slag off the base metals so as to produce a clean button and there is invariably so much base metal left after cupellation that the residue does not give reliable indication of the actual values present. The conclusions drawn from considerable study are (1) One or 2 fusions of the first slag are necessary for a complete collection of the Pt metals when much Ni is present. (2) Considerable quantities of Cu and Fe oxides do not prevent the collection of Pt metals in the Pb button. (3) Various silicates, excess PbO and KNO_3 charges over a wide temp. range do not serve to improve the recovery of Pt metals when much Ni is present. (4) In the absence of considerable Rh, Ir and Ru, proper washing of the Pb regulus permits the application of the all-dry assay. If the proportion of insol. to sol. Pt metals is high the assay bead is not coherent and Pb is retained even after heating 3 hrs. at 1300° in O_2. If 1 Pd, 1 Pt or more is present a wt. of concentrate should be chosen to make the residue weigh 10–15 mg. Even when a little Pb is retained, the absence of Ag facilitates the wet analysis of the regulus. (5) The all-dry assay has a limited application. It should be used primarily for the detection of the Pt metals but not for their detn. W. T. H.

Simple test for arsenic in lead alloys. R. G. Robinson *Analyst* **65**, 159(1940).—Heat 2 g. of alloy in a 250 ml. Erlenmeyer flask with 3 g. Na_2SO_4 and 15 ml. concd. H_2SO_4. When the alloy is completely decompd., cool, carefully add 75 ml. of water and heat to boiling. Add 75 ml. of concd. HCl and 2 drops $HgCl_2$ soln. + 3 ml. H_3PO_2, d. 1.114. Heat to boiling. All Pb salts will be dissolved and if 0.1 mg. or more of As is present, a brown colloidal ppt. will form. W. T. H.

Cerimetric determination of small amounts of arsenic after reduction with hypophosphite reagent. I. M. Kolthoff and Elias Amdur. *Ind. Eng. Chem., Anal. Ed.* **12**, 177–9(1940); cf. Evans, *C. A.* **26**, 5027.— The As is reduced to the free state by heating for 10 min. at 80–90° with excess of a soln. of $Ca(H_2PO_2)_2$ in 6 *N* HCl. The As is coagulated by heating, filtered, oxidized and dissolved in a measured vol. of approx. 0.005 *N* $Ce(SO_4)_2$ soln. The excess Ce^{++++} is titrated with 0.005 *N* arsenite soln. in the presence of OsO_4 as catalyst. The method will

detn. 1 mg. As within 0.5% of the truth, and 0.1 mg. As with 2%. Sb and Sn do not interfere. T. H. D.

Separation of cadmium from zinc by the use of granular aluminum. F. E. Townsend and Geo. N. Cade, Jr. *Ind. Eng. Chem., Anal. Ed.* **12**, 163–4(1940).—Expts. show that 0.06–0.10 g. of Cd can be sepd. from 0.01–2.0 g. of Zn by boiling the soln. in 0.2 *N* H_2SO_4 for 5 min. with 0.3–1.0 g. of granular Al. Filter through cotton and test the filtrate for more Cd by adding 0.1 g. of Al, boiling another 5 min. and filtering through paper. To the residue, add 5 ml. of 50% NaOH soln. and when all excess Al has dissolved, filter and wash the residue. Dissolve this in HCl + Br_2 and titrate the suitably treated soln. with $K_4Fe(CN)_6$ or electrolyze it. One pptn. with Al is usually adequate. Before making the $K_4Fe(CN)_6$ titration, interfering ions can be removed by pptn. with excess NH_4OH in the presence of NH_4Cl and before the electrolytic detn. interfering elements can be removed by pptg. the Cd as CdS. The electrolytic method is regarded as the more accurate but requires more time. W. T. H.

Colorimetric determination of columbium and tantalum. N. F. Krivoshlykov. *Trudy LKKhTI* **1939**, No. 7, 103–22; *Khim. Referat. Zhur.* **2**, No. 5, 59–60 (1939).—The method is based on the color produced by Cb and Ta compds. with pyrogallol in acid and alk. solns. The oxides of Cb, Ta and Ti are fused with $NaHSO_4$ and the soln. of the melt is treated with $(NH_4)_2C_2O_4$ soln. Ti is detd. with H_2O_2. For the detn. of Cb the soln. is mixed with an equal amt. of a 5% soln. of pyrogallol in a satd. aq. soln. of Na_2SO_3 and the intensity of the color is measured. Ta in an alk. soln. does not interfere with the detn. of Cb; Ti gives a color similar to that produced by Cb. A correction can be made for small amts. of Ti, detd. by the H_2O_2 method. If present in greater amt than Cb, Ti must be sepd. Ta is detd. colorimetrically with pyrogallol in an acid soln. without the use of Na_2SO_3. Cb and Ti do not interfere. By means of pyrogallol 0.05 mg. of Cb_2O_5 and 0.05–0.07 mg. of Ta_2O_5 in 1 cc. of soln. can be detected. W. R. Henn

Iodofluoride method for the determination of copper. Effects of antimony, aluminum and calcium. Wm. R. Crowell and Alan T. Spiher. *Ind. Eng. Chem., Anal. Ed.* **12**, 147(1940); cf. *C. A.* **34**, 2870.—The paper refers to the iodometric detn. of Cu when no previous elimination of other ions is effected and the effect of Fe^{+++} is prevented by conversion into FeF_6^{---}, which does not undergo reduction by contact with I^-. It is here shown that erratic results may be due to the presence of Sb, Al or Ca. Not more than 0.02 of Sb can be present or the results will be low and some I_2 will be used in oxidizing the Sb^{+++}. Not more than 0.3 g. of Al can be present as there is danger of an insol. fluoride forming which will carry some Cu down with it. Ca can be present up to 0.4 g. and Ca + Fe up to 0.3 g. of each. Ca, Fe and As can all be present up to 0.2 g. of each provided the sample is fumed well and any $CaSO_4$ ppt. is filtered off before adding NH_3. W. T. H.

Spectral-analytical determination of traces of iron in very pure aluminum. J. Wilken. *Metallwirtschaft* **19**, 121–4(1940).—The lines Al II 26669, 17 A. and Fe 2755, 7 A. were chosen. To prevent oxidation, all observations were made in an atm. of N_2. As neutral gas, neither H_2 nor A was satisfactory because these gases show strong continuous bands or lines. The results obtained in detg. 0.0025%, 0.0075%, 0.095% and 0.17% Fe are tabulated and complete details given concerning the procedure and the app. used. Except with 1 sample, the results appear to be within 4.3% of the truth. W. T. H.

New test for the detection of molybdenum and tungsten. J. Hubert Hamence. *Analyst* **65**, 152–4(1940).—Dithiol-(4-methyl-1,2-dimercaptobenzene) can serve to detect Mo and W. To detect either alone, take 10 ml. of soln. contg. between 0.02 and 1.0 mg. of the element and add NaOH soln. or HCl until neutral to litmus. Add 10 drops of concd. HCl and 3 drops of thioglycollic acid. If Mo is present a bright-yellow ppt. will form; W shows no color. Now add 1 ml. of the dithiol reagent (cf. Clark, *C. A.* **30**, 3741[9]). Mo now gives a dark-green ppt. and W a light greenish blue ppt. Cool the mixt. and add an excess of concd. NH_3 soln. Mo gives a bright-blue color but with W there is no color. The following procedure has been found satisfactory to detect W in the presence of Mo. To 20 ml. of soln. contg. 10 mg. Mo and 0.1 mg. W, add NaOH till basic to litmus, then 2 g. tartaric acid and 0.2 ml. of concd. H_2SO_4. Heat to 60° and sat. with H_2S. Filter off the MoS_3 ppt., evap. the filtrate to dryness and ignite to destroy tartaric acid. Add to the residue a few drops of 20% NaOH, dil. and test for W as above described W. T. H.

Estimation of praseodymium and neodymium in solutions from their absorption spectra. J. Newton Friend and Douglas A. Hall. *Analyst* **65**, 144–8(1940).—Three methods have been used for detg. rare earths by means of the absorption spectra shown by their solns. (1) The widths of the chief bands in the visible range are compared with bands obtained from known concns. (2) The diln. necessary to effect the disappearance of the most persistent band is detd. (3) The soln. studied is dild. until the intensities of suitable bands appear by direct vision to equal those of standard solns. placed in juxtaposition. This last procedure has often been used to det. traces of Pr, Nd and other colored earths in modern at.-wt. detns. The work described in this paper was undertaken to det., in the case of the nitrates of Pr and Nd, the accuracy of the procedure and to ascertain what concns. of HNO_3, $Ce(NO_3)_3$ and $Mg(NO_3)_2$ can be present without appreciably affecting the results. A Hilger const.-deviation spectrometer was used and illuminated by 40-watt, gas-filled, opal lamps. The absorption cells were 6 cm. long and the slit was set at the min. to yield a clear spectrum with least eye strain. The results show that in solns. contg. about 3–4% of Nd or Pr nitrate the concn. of either element separately can be detd. within about 1% of the truth by comparing the intensities of suitable bands with those of standard solns. For Nd three bands were selected yielding, resp., (*a*) lines at 5263 and 5203 A., (*b*) a line at 5216 A. and (*c*) a line at 5203 A. For Pr, the most suitable band extended from 5980 to 5825 A. and yielded 5890 A. as the most persistent line. There is considerable overlapping of the Pr and Nd bands; it is possible to det. Nd in the presence of as much as 50% Pr with an accuracy of about 1%. In the case of Nd, the presence of 63 g. HNO_3, 70 g. $Mg(NO_3)_2$, 85 g. $NaNO_3$, 65 g. $Ce(NO_3)_3$ or 76 g. $La(NO_3)_3$ per l. is tolerated and for detg. Pr, 50 g. HNO_3, 60 g. $Mg(NO_3)_2$ or 65 g. $Ce(NO_3)_3$ does no harm. W. T. H.

A modified tin subgroup procedure. A. R. Hanke and J. H. Reedy. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 104–5(1939).—A procedure based on the reduction of Sb^{+++} and Sn^{++++} by sheet lead to Sb and Sn^{++}, resp. J. H. Reedy

Determination of tungsten. A volumetric method. M. L. Holt and Allen G. Gray. *Ind. Eng. Chem., Anal. Ed.* **12**, 144–6(1940).—The method is based upon the reduction of H_2WO_4 to W^{+++} in the presence of HCl by treatment with Pb-Hg amalgam at 60°. As soon as the liquid amalgam comes in contact with the sexivalent W, a blue color develops. The color changes to violet, red, yellow and finally to a deep yellow. This deep yellow color signifies complete reduction but it is well to keep the strongly acid soln. in contact with the reductor for about 5 min. longer. Then the reductor is removed, the soln. is treated with an excess of ferric alum soln. and the reduced Fe^{++} titrated with $K_2Cr_2O_7$ in the presence of diphenylaminesulfonic acid as indicator. W. T. H.

New applications of the silver reductor. Determination of uranium and copper. Nathan Birnbaum and Sylvan M. Edmonds. *Ind. Eng. Chem., Anal. Ed.* **12**, 155–7 (1940).—UO_2^{++} in the presence of hot, 4 *N* HCl is reduced completely to U^{++++} by the Ag reductor and the reduced soln. can be titrated with $Ce(SO_4)_2$ soln. in the presence of *o*-phenanthroline ferrous complex as indicator. In 2 *N* HCl, Cu^{++} is reduced to $Cu_2Cl_4^{--}$. Direct titration of the cuprous salt gives low results because of atm. oxidation. If, however, the reduced soln. is run into ferric alum soln., this serves to prevent low results and the soln.

can then be titrated with $Ce(SO_4)_2$ in the presence of *o*-phenanthroline ferrous complex. The presence of HNO_3, Fe, Mo, V and Cu interfere with the detn. of U by means of the Ag reductor but in the detn. of Cu, the presence of HNO_3, Zn, Sn, H_3AsO_4, Bi and Cd do no harm. Otherwise the results are excellent for both detns. W. T. H.

Determination of vanadium in ferromanganese. N. Motohasi. *Bull. Inst. Phys. Chem. Research* (Tokyo) **18**, 196-203(1939).—The $FeSO_4$-persulfate method for detg. V in Fe-Mn can be used after removal of Mn by Na_2O_2. Much Mn renders the end point of the titration indistinct. B. C. P. A.

Empirical mercurimetric method for zinc. Albert C. Titus and Jack S. Olsen. *Ind. Eng. Chem., Anal. Ed.* **12**, 133-5(1940).—A routine method is described which is suitable for the analysis of many samples with speed and satisfactory accuracy. The procedure consists in pptg. the Zn as $ZnHg(SCN)_4$ from an acid soln., dissolving the washed ppt. in standard KI soln. and titrating the apparent excess of KI with standard $Hg(NO_3)_2$ soln. If the method were strictly stoichiometric, the $ZnHg(SCN)_4$ would react with 4 I^- to form $Zn^{++} + HgI_4^- + 4SCN^-$ and the excess I^- would react with Hg^{++} in the final titration to form HgI_4^{--}. In practice a pos. error is caused by the fact that the red ppt. of HgI_2, which indicate the end point forms before enough Hg^{++} has been added, by the reaction $Hg^{++} + HgI_4^-$ and a neg. error results from too much Hg being used for the initial formation of $ZnHg(SCN)_4$. The relationship between the apparent iodide consumption and the actual quantity of Zn present is a straight-line function so that an empirical curve can be constructed which will serve for calcg. the results. W. T. H.

Indicator available for the determination of nitrogen in iron and steel. Isaburo Wada and Raizo Isii. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **37**, 65-78 (1940).—The standard procedure adopted in Japan for detg. N in Fe and steel consists in dissolving the sample in HCl, adding excess NaOH to the resulting soln., distg. off NH_3 into a known vol. of standard H_2SO_4 and titrating the excess acid with NaOH to an end point with Na alizarinsulfonate as indicator. It is now shown that bromocresol blue is a more satisfactory indicator for this reaction. W. T. H.

Determination of nitrogen in iron and steel by the Kjeldahl method. I. New apparatus for the distillation. Takayuki Sōmiya. *Tetsu-to-Hagane* **26**, 43-6(1940). - Details of the manipulation and app. are changed somewhat. M. Ishida

Microdetermination of amino nitrogen by the manometer method. Danzi Matukawa. *Saikingaku Zasshi* No. **520**(May, 1939); *Kitasato Arch. Exptl. Med.* **16**, *Abstracts* 3(Nov., 1939).—A combination of Warburg's manometer method and the formalin titration method is recommended. J. Pinchack

Determination of amino nitrogen with formalin and degree of digestion of various peptone preparations determined by amino nitrogen. Danzi Matukawa. *Saikingaku Zasshi* No. **520** (May, 1939); *Kitasato Arch. Exptl. Med.* **16**, *Abstracts* 3(Nov., 1939).— A modified Sorensen formalin titration method and Willstatter's alc. method were applied. A partly digested peptone is necessary for toxin production, but when digestion has gone too far strong toxin is not produced although the organisms grow well. J. Pinchack

Rapid determination of oxygen in steel. L. Singer. *Ind. Eng. Chem., Anal. Ed.* **12**, 127-30(1940).—The procedure is like that of the well-known vacuum fusion method except that a temp. of 1200-1250° suffices and the oxidation of the C in a graphite bucket by the O of the oxide or dissolved O_2 present in the steel is accomplished in an atm. of pure N_2. The N_2 is passed through a purifying train to remove small quantities of H_2 and O_2 that are present. The sample is weighed into a conditioned graphite bucket which is provided with a layer of pure Sn; this effects the fusion of the steel at a temp. lower than would be necessary otherwise. Most of the air is removed at the start by applying a vacuum and then the N_2 stream is started. About 15 min. is all that is required for the analysis. The CO formed is passed over hot CuO and the resulting CO_2 is absorbed in ascarite after the gas is properly dried. A blank must be run which, for a 15-g. sample of steel, is about 0.0005% for each 5 min. of reduction period. In detg. 0.012 0.025% O in steel the results usually agree within 0.001%. W. T. H.

An adaptation of the Bodansky method for phosphorus to the photoelectric colorimeter. Morris Rhian. *Proc. S. Dakota Acad. Sci.* **19**, 115-17(1939); cf. B., *C. A.* **31**, 8573[4]. Walter H. Seegers

Quick method for determining silicon in iron and steel. Raizo Isii. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 491-6(1939).—The Si is estd. from the vol. of silicic acid (I) formed from the HCl soln. Heat 1 g. of steel or 2 g. cast Fe with 10 cc. of 6 *N* HCl (with cast Fe preliminary treatment with 2 *N* HCl is advisable) add 1 cc. of concd. HNO_3 and heat the mixt. cautiously until the vol. is reduced to 1-2 cc. Now add about 5 cc. concd. HCl and evap. again to 1-2 cc. Dil with 20 cc. H_2O and centrifuge in a conical, graduated measuring tube. The method fails when less than 0.1% Si or appreciable W is present. C. R. Addinall

Spectroscopic analysis of zinc alloys. Gisela Lueg and F. Wolbank. *Metallwirtschaft* **18**, 1027-9(1939). A special permanent casting mold was used; the elec. equipment is described. A spark generator in resonance wiring was used. It is necessary to take several pictures for each group which differ by exposure time. With each analysis a series of standard alloys with at least 3 different alloying percentages is used. For detg. Al, Mg and Cu the intensity of the following lines was measured: Al 3082 A. against Zn 3076 A., Mg 2798 A. against Zn 2801 A., Cu 2545 A. against Zn 2570 A. The tested concn. ranges were, 2-13% Al, 0.01-0.1% Mg and 0.3-3% Cu. The comparison (standard) alloys for detg. Mg should have approx. the same Al content as the analyzed material. The most important impurities Fe, Cd and Pb were measured by lines: Fe 2382 A. against Zn 2394 A., Cd 2144 A. against Zn 2138 A., Pb 2204 A. against Zn background next to the line. The comparison with the background calls for most uniform exposure. Richard P. Seelig

Microchemical examination of Prussian blue writing ink. Cecil L. Wilson. *Chemistry & Industry* **1940**, 163.- In exams. the ink on a forged British bank note, treatment with 5 *N* HCl gave a soln. which showed a pos. Fe^{+++} test with ferrocyanide. Treatment with $(CH_2)_6N_4$ as recommended by Chamot and Mason (*Handbook of Chem. Microscopy*, *C. A.* **25**, 2635) gave rise to the formation of prisms and rectangular plates which showed strong birefringence and parallel extinction. According to C. and M. the extinction should be oblique in the ferrocyanide test. Expts. made with Prussian blue confirmed the conclusion that the ink used in the forgery contained Prussian blue and oxalic acid. W. T. H.

Separation of chloride, thiocyanate and cyanide, and a qualitative test for chloride in potassium thiocyanate. A. Slooff and D. van Duyn. *Chem. Weekblad* **37**, 69-72 (1940).—Slight changes in the exptl. procedure are suggested. The test for Cl^- is made after boiling with dil. HNO_3 to oxidize HCN + HCNS. J. C. Jurrjens

Analysis of free sodium cyanide in brass-plating solutions. Wallace M. McNabb and Samuel Heiman. *Ind. Eng. Chem., Anal. Ed.* **12**, 161-3(1940).—Pan (*C. A.* **26**, 4758) in applying the argentometric method of Liebig (*Ann. Chem. Pharm.* **77**, 102) to the detn. of free cyanide came to the conclusion that in brass plating solns. the *free cyanide* can be regarded as the alkali cyanide that is present over that required to form $Na_2Cu(CN)_3$ and $NaZn(CN)_3$. P. did not test the purity of his reagents and did did not study the effect of pH. The expts. here described show that the Liebig method yields reproducible results only when the concns. of Na_2CO_3, NH_3 and the pH are controlled carefully. Although under certain conditions the results indicate mathematically that $Na_2Cu(CN)_3$ and $NaZn(CN)_3$ are formed, yet there is no pos. proof that the latter compd. really exists. In fact it seems more plausible that a brass plating soln. is likely to contain a

mixt. of $NaCu(CN)_2$, $Na_3Cu(CN)_4$, $Na_2Zn(CN)_4$ and Na_2ZnO_2. The equil. between these complexes, and consequently the actual free cyanide, is governed by the pH and the concns. The Liebig titration, however, is useful for evaluating plating solns. W. T. H. 1

Analysis of cyanide slimes. J. A. Klyushnikov. *Zolotaya Prom.* **1938**, No. 11, 39–40; *Khim. Referat. Zhur.* 2, No. 5, 83(1939).—The slime obtained from the cyanide process is dried, sifted through a 1-mm. sieve and divided into 2 equal portions, each of which is in turn divided in 5 parts. Each part is carefully mixed and samples are taken by quartering for detns. H_2O, Au, Ag and Zn. Au and the other components are detd. by dry assay. W. R. H. 2

Rapid methods for determining free sulfur trioxide in fuming sulfuric acid. Zyoosuke Kubota. *Waseda Applied Chem. Soc. Bull.* **16**, No. 2, 3–10, *Abstracts* (in English) 19(1939).—To secure a rapid and accurate method for the detn. of "free SO_3" present in oleum K. examd. (*a*) the fume-vanishing method, (*b*) thermometric titration and (*c*) the thermal method based on the detn. of temp. rise. Of these methods *b* with dil. H_2SO_4 gave the best results; the titration could be carried out with water, though the results obtained were somewhat inferior to those with dil. acid. In the temp.-rise method oleum to be examd. and H_2SO_4 to be admixed therewith were measured volumetrically rather than gravimetrically. The app. and procedures of the 3 methods used by K. are detailed along with the results obtained and crit. observations. E. J. C. 3

Analytical procedures employing the Karl Fischer reagent. IV. Determination of acid anhydrides. Donald M. Smith, W. M. D. Bryant and J. Mitchell, Jr. *J. Am. Chem. Soc.* **62**, 608–9(1940); cf. *C. A.* **34**, 1276[2,4].—The method depends upon complete hydrolysis of the anhydride in the presence of excess H_2O and subsequent titration of the residual H_2O with the Karl Fischer reagent (*C. A.* **29**, 6532[2]). It is best suited for the detn. of acyclic aliphatic anhydrides. Analytical data are given for acetic, propionic, butyric, crotonic, valeric, caproic, heptylic, glutaric, benzoic, furoic, succinic, maleic and phthalic anhydrides. A. B. Garrett 4

Potentiometric titration of the antimonic ion with the aid of potassium iodide and sodium thiosulfate. G. Spacu and C. DrAgulescu. *Bull. sect. sci. acad. roumaine* **21**, 85–105(1938–39).—In neutral solns. Sb can be oxidized completely from the valence 3 to 5 by means of I_2 provided $NaHCO_3$ or Na_2HPO_4 is present to prevent the soln. becoming acid. H_3SbO_4, on the other hand, can be reduced completely to $HSbCl_4$ by means of HI in the presence of considerable HCl. The last reaction is slow, however, and it is more advantageous to make the reaction take place quantitatively by adding $Na_2S_2O_3$, which reacts with the I_2 formed by the action of HI on quinquevalent Sb. In this paper, the results obtained in a series of potentiometric detns. show that for titrating 67 mg. of Sb in 100 ml. of soln., the HCl soln. must be at least 1.2 *N* and good results can be obtained when only a slight excess of KI is added. W. T. H. 5

Technique for micro and semimicro elementary organic analysis for carbon and hydrogen, using the apparatus of Natelson, Brodie and Conner. Humberto Teixeira Cardoso *Mem. inst. Oswaldo Cruz* **34**, 441–6(1939); cf. Natelson and Conner, *C. A.* **32**, 4470[2], Natelson, Brodie and Conner, *C. A.* **32**, 8986[9]. L. E. Gilson 6

Semimicrodetermination of nitrogen by method of Dumas. F. Cruz. *Rev. centro estud. farm. bioquim.* **29**, 137–45 (1939). —The construction and operation of an app. suitable for samples yielding not more than 5 cc. N_2 gas are described. L. E. Gilson 7

Importance of chemical tests for detection of seminal stains in medico-legal investigations. K. N. Bagchi. *Indian Med. Gaz.* **74**, 683–6(1939).—Since choline, upon which the development of choline periodide crystals constituting the Florence test depends, may be decompd. by bacteria, a neg. test has no medico-legal value, but no biol. fluid other than semen contains it. Therefore a pos. test is of value, reliable in aspermia or when spermatozoa are not demonstrable. J. McAfee 8

Determination of formaldehyde with dimedon. The fate of formaldehyde in the process of toxoid preparation. Danzi Matukawa. *Saikingaku Zasshi* No. 520(May, 1939); *Kitasato Arch. Exptl. Med.* **16**, *Abstracts* 2(Nov., 1939); cf. *C. A.* **34**, 2284[3].—The method is applicable when over 0.1 mg. CH_2O is present. The concn. of CH_2O in the prepn. of toxoid is parallel with fixation. J. P. 9

A new color test for ketones. S. M. Efros. *Trudy LKKhTI* **1939**, No. 7, 123–6; *Khim. Referat. Zhur.* 2, No. 5, 65(1939).—A soln. of $K_4Fe(CN)_6$ with NH_4 molybdate gives a brown color with certain ketones. The sensitivity of the test with acetylacetone is about 1.6 γ/cc. and for dipropyl ketone 114 γ/cc. Other ketones give unstable or very slight colorations. The test is useful for detg. acetylacetone in the presence of other ketones. W. R. Henn 10

A new method for clarification of plant extracts for the determination of reducing sugars. B. W. Doak. *New Zealand J. Sci. Tech.* **21B**, 90–5(1939).—An application of the method of Fujita and Iwatake (*C. A.* **26**, 1313) accomplishes efficient clarification without any loss of fructose or glucose. $CdSO_4$ soln. can bring about clarification at a dilu. suitable for the direct application of micromethods. Basic Pb acetate, NaOAc + alum, $CaCl_2$ + NaF, colloidal SiO_2 and a mixt. of Na_2WO_4 + alum were tested. All gave high values except the last and this had no advantage over $Cd(OH)_2$, which removes more reducing substances from grass exts. than does $Zn(OH)_2$. Clarification with $Cd(OH)_2$ is almost as efficient as with basic Pb acetate, does not destroy fructose and glucose and can be applied directly to alc. exts. Reducing substances left after $Cd(OH)_2$ clarification were fermentable by yeasts. Analyses for reducing sugars were made by the Fujita and Iwatake modification of the original Hagedorn-Jensen (*C. A.* **17**, 2721) ferricyanide method. 14 references. F. W. Marsh 11

Microscopic identification of sugars. R. J. Martin and A. M. Rongiovanni. *Mendel Bull.* **12**, 46–7(1940).—A comparative study of the osazone test and that described by Quense and Dehn (*C. A.* **33**, 9199[5]). J. S. H. 12

Modified method for determination of benzene in air. J. Siegel and W. J. Burke. *Ind. Bull.* (N. Y.) **18**, 17–18 (1939).—A modification of the microcolorimetric method developed at the U. S. Bureau of Mines is reported. B. C. P. A. 13

Determination of acetanilide. G. Vaisman. *Farmatsiya i Farmakol.* **1938**, No. 4, 17; cf. *C. A.* **27**, 3557.—The poor results obtained by Khaletskĭ and Mikryukova (cf. *C. A.* **33**, 9200[6]) were caused by failure to follow the directions. W. A. Moore 14

Potentiometric estimation of glucose with potassium ferricyanide in sodium carbonate solution. H. T. S. Britton and Leslie Phillips. *Analyst* **65**, 149–52(1940); cf. *C. A.* **34**, 1592[3].—The titrations described were carried out in a cell combination of $Pt/K_3Fe(CN)_6$ + Na_2CO_3 + glucose soln./satd KCl soln./*N* KCl/*N* calomel. The solns. were titrated with glucose soln. added to the soln. of ferricyanide + Na_2CO_3 which was kept at approx. 100°. The completion of the reduction of the ferricyanide was shown clearly by inflections in the curves formed when e. m. f. was plotted against vol. of glucose added. It took 20–30min. to titrate to the inflection but after that the titration was even slower. In the concns. used 5.9 mols. of ferricyanide was required to oxidize 1 mol. of glucose. The potentiometric titrations also show that methylene blue is a suitable indicator for the reaction. W. T. H. 15

Colorimetric microdetermination of some phenols. A. Ionescu-Matiu, Const. Popesco and Ana Popesco. *J. pharm. chim.* **30**, 49–58(1939).—Phosphotungstic acid (*A*) is used as the color reagent. For reoxidation, $K_3Fe(CN)_6$ reagent (*B*) in presence of a 20% aq. soln. of $Na_2CO_3.10H_2O$ is used. To prep. *A*, boil 10 g. Na tungstate and 8 cc. H_3PO_4 (d. 1.71) with 90 cc. H_2O under reflux for 1.5 hrs., cool and fill to 100 cc. To prep. *B*, dissolve 1.65 g. $K_3Fe(CN)_6$ with 1.65 g. KOH in H_2O to make 100 cc. (= a 0.1 *N* soln.; verify by Mohr's method). The phenol solns. (*C*) are about 0.1%. Mix *C* with *A*, make alk. with Na_2CO_3 soln. and titrate with *B* until the blue color 16

turns a final lemon yellow; pyrocatechol produces pink. The equivs. of 1 cc. of 0.1 *N B* are, in g., as follows: pyrocatechol 0.001376; hydroquinone 0.002752; pyrogallol 0.0010578; gallic acid 0.0015675; tannin 0.001923; tannigen 0.002525; quinine tannate 0.003125. Phloroglucinol gives neg. results; also phenol (cf. *C. A.* **32**, 7904[8]). All other results are accurate when the quantities indicated in a table are taken. S. Waldbott

Color reaction for β-naphthol identification and determination of very small quantities. J. A. Gautier. *J. pharm. chim.* **30**, 70-8(1939).—To 1 cc. of β-naphthol (*A*), 0.05 *M* – 0.001 *M* in 30% alc. soln., add $NaNO_2$ in 0.1 *M* soln. 1 drop to 2 cc., then a vol. of *N* HCl = that of the $NaNO_2$ soln., and dil to 10 cc. with H_2O. A pink or red-dish color develops. If 0.1 mol. of *A* is taken, a noncharacteristic yellowish ppt. is formed. Within the limits given, the intensity of the color is proportional to the concn. S. Waldbott

Determination of sterols. I. V. V. Oppel and A. A. Grigor'eva. *Biokhimiya* **3**, 175-89(in English, 189-90) (1938); *Chimie & industrie* **41**, 527; cf. *C. A.* **33**, 2927[9].—A study of the Liebermann-Burchard method based on the formation of a green color. The intensity and shade of the color vary according to the solvent used; from this standpoint $CHCl_3$ is preferable to C_6H_6, as solns. of sterols in the latter change more rapidly from green to brown. The intensity of the color of solns. of mixts. of sterols is equal to the sum of the colors due to the individual constituents. A. Papineau-Couture

Availability of Mn in natural and pptd. $MnCO_3$ [detn. of Mn] (Bandemer, *et al.*) **11E**. Hg cathode in metallurgical analysis (Pavlish, Sullivan) **4**. Structural chem. investigations—nickelous-ion-specific groups (Erlenmeyer, Ueberwasser) **10**. Identification of org. compds. (Huntress, Carten) **10**.

Caron, H., and Raquet, D.: Tableaux d'analyse chimique qualitative, à l'usage des étudiants en P.C.B., en pharmacie, des élèves des écoles de chimie. 3rd ed. Paris: Vuibert. 88 pp. Fr. 45.

Evans, William L., Garrett, Alfred B., and Quill, Laurence L.: Semimicro Qualitative Analysis. Boston: Ginn and Co. 246 pp. $2.00.

Analyzing gases. G. F. Knorre. Russ. 55,939, Oct. 31, 1939. Gas under pressure is passed at const. vol. velocity into the lower part of an absorption vessel and the amt. absorbed is detd. by the change of the liquid level in the absorption vessel

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Note on the fluorine content of rocks and ocean-bottom samples. E. S. Shepherd. *Am. J. Sci.* **238**, 117-28 (1940).—The Willard and Winter procedure (cf. *C. A.* **27**, 681) furnishes an easy and accurate method for F detn. Analyses of >100 samples show that F is present in rocks in about the same amt. as Cl and must be considered in rock analysis. A tentative av. of 0.04% is suggested. Ocean-bottom samples contain about the same quantities as rocks. F content varies with nature of the material. Alden H. Emery

Isotopic composition of oxygen in carbonate rocks and iron oxide ores. Malcolm Dole and Robert J. Slobod. *J. Am. Chem. Soc.* **62**, 471-9(1940).—The variations in the oxygen-isotope ratios were detected by means of the totally submerged float method; the temp. of the floating equil. was measured with a Pt resistance thermometer. No significant difference in the isotopic compn. of the O in the rocks as a function of age was detected for Grenville Marble, Niagara dolomite, Pennsylvania limestone and clam shells, all carbonates of widely different geol. age. A table of change in d. due to O alone is given for these different carbonates. D. variations observed for carbonates decompd. with acid or with heat are attributed to the isotopic fractionation which takes place when the carbonate ion is decompd. by acid. The observed d. variation resulting from the thermal treatment is explained quantitatively with the aid of the isotopic exchange equil. theory of Urey and Greiff (cf. *C. A.* **29**, 2842[1]). The O in iron ores of the Keewatin and Middle Huronian ages does not differ significantly in its isotopic compn. from that of O in normal H_2O, the slight excess d. observed in the expts. on the oölitic and fossil type Silurian ores is probably due to the presence of carbonates in the ores. A. B. Garrett

Jordanite, wurtzite and rhodocrosite from the Yumo-Sawa mine. M. Watanabe and O. Nakano. *J. Japan. Assoc. Mineral. Petrol. Econ. Geol.* **15**, 211-23(1936); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 801.—Thin alternate layers of jordanite and wurtzite form crustlike overgrowths on barite in druses in a Tertiary epithermal vein carrying barite, galena and sphalerite. Radial overgrowths of wurtzite are also frequent. Formation at a low temp. is indicated. C. A. Silberrad

Blue rock salt. J. Newton Friend and John P. Allchin. *Nature* **145**, 266-7(1940).—A sample of blue anhydrite contained 4 p. p. m. Au; a deep blue Stassfurt halite contained 23 p. p. m. Au. Au was found in blue and pink halite from other sources. If the Au is in the colloidal condition, it would be ample to account for the observed color. Other theories of the color of halite are reviewed, with 8 references. G. M. Petty

Crystallographic and minerogenetic investigation of fluorite from a new locality in Bulgaria. Ivan Kostov. *Ann. univ. Sofia, II. Faculte phys.-math.*, Livre 3, **35**, 255-89(in German, 290-2)(1938-9).—A detailed discussion is given of the minerals assocd. with the fluorite, the habits of the fluorite crystals, and the mode of origin, which is replacement of limestone by magmatic emanations. W. F. Bradley

Hydrated cobalt oxides of Katanga. V. Billiet and A. Vandendriessche. *Bull. soc. belge géol., paléontol hydrol.* **49**, 63-78(1940).—X-ray examn. of 2 samples of stainerite, one of mindigite, 2 of trieuite and 3 of heterogenite of different origins (Katanga, Nevada and Ontario), considerations of the best recorded analyses, with one new one (of trieuite) and dehydration results, and the fact that an apparently vitreous sample of trieuite was transformed into a cryst form resembling that of the other samples by heating in steam under pressure, lead to the conclusion that all are merely hydrated oxides of Cu and Co of compn. $(CuO.Co_2O_3)H_2O$, differing in the ratio CuO Co_2O_3, and in hygroscopic H_2O. It is, therefore, proposed to designate all as the heterogenite group, abandoning the other 3 names. 20 references. C. A. Silberrad

Iceland spar mine in New Mexico. J. Harlan Johnson. *Mines Mag.* (Colo. School of Mines) **30**, 59-60(1940).—A discussion of sources of Iceland spar, its properties and uses, location of deposits in New Mexico, geology, origin and methods of mining. Leopold Scheflan

Cerussite at Tisovo near Valjevo (Western Serbia). St. Pavlovitch. *Bull. serv. géol. roy. Yougoslav.* **7**, 313-27 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 257.—The Pb ores of Tisovo and of the tract extending 25-30 km. to Medvednik consist mainly of cerussite in mid-Triassic diplopore limestone, which is bounded by propylitized and partially silicified microdiorite. The cerussite, though usually white, often contains a kernel of, or is enclosed in galena. This black cerussite contains more (up to 78.28 %) Pb than the white (to 67.56%). Occasionally it is red from limonite, goethite or pyrite and then contains Au (up to 12 g./t.). When pink or yellow, As is present (up to 9.38-12.38%). The formation of the deposit has resulted from (1) a porphyritic intrusion, preceded and followed by fissuring; (2) metasomatic ore accumulation in the limestone; (3) further tectonic activity and (4) oxidation of

galena by surface water along fissures, which extends to a depth of some 200 m. C. A. Silberrad

Structure of orthoclase. S. H. Chao, A. Hargreaves and W. H. Taylor. *Mineralog. Mag.* **25**, 498–512(1940); cf. *C. A.* **27**, 5684; **28**, 3691⁸.—The orthoclase examd. was glass-clear from the Ruby Mines, Mogok, Burma, and contained K_2O 9.1, Na_2O 6.5 and lime-feldspar 2.5% (cf. Spencer, *C. A.* **31**, 3827⁴). The structure has been quantitatively detd., diffraction diagrams and at. coordinates given for all constituents to a probable accuracy of less than ±0.1 A. The results are discussed at length and compared with those for sanidine. C. A. Silberrad

Celestite at Rochefort. Pierre de Béthune. *Bull. soc. belge géol., paléontol. hydrol.* **49**, 128–31(1940).—The celestite occurs in geodes in limestone at Rochefort (30 miles S.E. of Namur). The larger crystals are pale blue, smaller practically colorless, they are crystallographically described, d. 3.92. The lightness is probably due to numerous inclusions, apparently liquid. C. A. Silberrad

Bavenite in Switzerland. G. F. Claringbull. *Mineralog. Mag.* **25**, 495–7(1940); cf. Schaller and Fairchild, *C. A.* **26**, 5515.—Bavenite occurs at 2 localities in the neighborhood of Graubunden (Grisons). It is assocd. with albite, adularia, chlorite, etc.; x-ray examn. gives a 19.34, b 23.06, c 4.95 A., indicating probably 4 mols. of $Ca_4(Si_9Al_2Be)O_{24}(OH)_2$ as the unit cell (cf. Ksanda and Merwin, *C. A.* **28**, 1305⁹). Spectrum analysis indicates the presence of minute quantities of B, Mg and Fe. C. A. Silberrad

Polymorphism of the micas. Sterling B. Hendricks and Merrill E. Jefferson. *Am. Mineral.* **24**, 729–71(1939).—X-ray examn. of 99 micas showed 7 different cryst. modifications. There were 45 of the single-layer monoclinic hemihedral type with space group $C_s^1 - Cm$, $a_0 = 5.3$, $b_0 = 9.2$, $c_0 = 10.2$ A. In the unit of structure there are 2 mols. of $[R_3(Al,Si)_4O_{10}(OH,F)_2K]$ (I) where R = Mg^{II}, Fe^{II}, Fe^{III}, Li^{I}, Ti^{IV}, etc. Five micas were two-layer monoclinic holohedral, octophyllite type, with 4 I in unit of structure. Space group is $C_{2h}^6 - C2/c$ and a_0, b_0 and c_0 = 5.3, 9.2, and 20.2 A., resp. 21 micas were also two-layer monoclinic holohedral, space group $C_{2h}^6 - C\,2/C$, but showed (06l) reflections with l odd. This is the muscovite type and has a_0, b_0 and c_0 = 5.2, 9.0 and 20.0 A. The unit of structure is $4[(Al,R)_2(Al,Si)_2O_{10}(OH,F)_2K]$. The 3-layer rhombohedral enantiomorphic hemihedral structure with $D_3^3 - C_3^1 12$ or $D_3^5 - C_3^2 12$ occurs in 8 specimens; $a = 5.3$, $c_0 = 30.0$ A.; unit of structure is 3 I. 6-layer monoclinic hemihedral with $C_s^1 - Cc$ occurs 3 times; a, b, c = 5.3, 9.2, 60.0 A.; unit is 12 I. 6-layer triclinic holohedral, $C_i^1 - P\bar{1}$, occurs 3 times; a, b, c = 5.3, 5.3, 60.0 A.; unit is 6 I. One example of 24-layer triclinic holohedral, $C_i^1 - P\bar{1}$, a, b, c = 5.3, 5.3, 240.0 occurs; structure unit is 24 I. In 13 micas mixts. of the various structures exist. Diffuse scattering of x-rays in some crystal zones is explained. C. H. Hale

Chemical constitution of Belgian clays. C. Camerman. *Bull. soc. belge géol., paléontol. hydrol.* **49**, 80–115(1940).—An account is given of the clays of Belgium, of which there is a large variety and quantity, classified according to their geological origin and the uses to which they are put. 120 analyses. C. A. Silberrad

Djalmaíta, a new radioactive mineral. Caio Pandiá Cuimaraens. *Ann. acad. brasil. sci.* **11**, 347–50(1939).—A crystallographic study of djalmaíta, recently discovered in Brazil, (n 1.97) is followed by a chem. analysis of the mineral: Ta_2O_5 72.27, Cb_2O_5 1.41, TiO_2 2.54, SnO_2 traces, ZrO_2 0.80, UO_2 2.17, UO_3 9.38, WO_3 0.18, Bi_2O_3 0.98, PbO 1.10, FeO 0.56, CaO 3.40, MgO 0.24, H_2O 4.62. A brief summary of the properties is given. A. H. Krappe

Minerals from deep sea cores and surface deposits of Bermudian calcareous sediments. John A. Young, Jr. *Am. J. Sci.* **237**, 798–810(1939).—Biotite, pyroxene, some if not all of the minerals of the accessory group, serpentine, possibly hornblende, and the feldspars, except microcline could have been derived from the volcanic series underlying the islands. Phillipsite, glauconite, and Fe oxides probably were formed by chem. alteration on the sea bottom from the minerals derived from volcanic rocks. The only mineral of any importance for whose origin it seems necessary to look elsewhere is quartz. Alden H. Emery

Boxhole meteoritic iron, Central Australia. C. T. Madigan. *Mineralog. Mag.* **25**, 481–6(1940); cf. *C. A.* **34**, 1596⁹.—The Boxhole meteorite crater is some 120 miles north of Alice Springs, in it fragments of Fe and shale balls have been found. The former show the meteorite to be a medium octahedrite contg. kamacite, taenite, plessite, hydrated lawrencite and brassy grains of troilite, av. d. 7.80. Analysis, Fe 91.77–91.54, Ni 7.80–7.54, Co 0.44–0.37, P 0.08, S 0.03–0.01, C 0.049–0.013, SiO_2 0.01–0.03. Sections are described in detail with photomicrographs. C. A. Silberrad

Rare and nonferrous metals; metallogeny of Central Caucasus. P. S. Saakyan. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) **147**, 19–33(in English, 33)(1939).—Preliminary analyses indicate 4 types of acid intrusions in the recently surveyed deposits of the region: (1) quartz-type intrusions, contg. Au and rare metals, in the Precambrian porphyry-like granites; (2) Sn-bearing pegmatites in the Precambrian even-grained granites; (3) Au-bearing quartz in the Variscian red granites, and (4) sulfidic minerals (As, Mo, W and Sb) in the Alpine granodiorites. Chas. Blanc

Some australite structures and their origin. George Baker. *Mineralog. Mag.* **25**, 487–94(1940).—The structures of several glassy australites are minutely described. All are consistent with the view that the glassy material became plastic and evolved, or was accompanied by hot gases on its passage through the atm. A specimen was unaffected by 2 months immersion in concd. HCl or KOH. C. A. Silberrad

Geology of Baguio gold district (Philippine Islands). A. Leith. *Geol. Survey, Philippines, Bur. Mines, Tech. Bull.* **9**, 91 pp.(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 801.—Andesite dikes penetrated rocks of various kinds in Pliocene times, causing much contact metamorphism and epithermal Au mineralization, and forming long systems of veins. The enclosing rock is intensely propylitized, kaolinized and silicified. Some veins contain calcite, quartz, and rhodocrosite, with Au, others only quartz and Au. Sulfides are almost absent and tellurides rare. The ratio Au:Ag = 1.8:1. C. A. Silberrad

Young volcanic gold and silver deposits of the Carpathian arc. Adolf Heike. *Arch. Lagerstattenforsch.* No. **66**, 175 pp.(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 791–4. A detailed and comprehensive account of these mixed deposits, which include native Au, ores of Te and Au, pyrite, marcasite, magnetic pyrite, mispickel, chalcopyrite, sphalerite, galena, tetrahedrite, stibnite, berthierite, bournonite, Pb-Sb sulfides, rhodocrosite, barite, siderite, and fluorite. Numerous photomicrographs and analyses are given. The ores are of typically hydrothermal origin, and were probably formed at temps. not exceeding 350°, and in the case of the Te ores below 184°. They appear to be connected with a batholith at comparatively small depth. C. A. Silberrad

Geology and petrology of the gold mine at Valea lui Stan (Rumania). St. Ghika-Budesti. *Dări de seamă ale Sedintelor* **22**, 33–6(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 796.—Following on regional metamorphism accompanied by tectonic movements and consequent perimagmatic phenomena the hydrothermal phase resulted in the introduction of mispickel, pyrite, chalcopyrite and Au. Subsequent movements caused mylonitization. C. A. S.

Geology and natural resources of Tannu-Tuwa (Urjanchai). H. Hauser. *Z. prakt. Geol.* **46**, 199–207, 228–33 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 391–4.—A detailed description is given of the Au placers at the headwaters of the Yenisei, also of occurrences of Pt and iridosmium. Near contacts between granite and other plutonic rocks are indications of chalcopyrite, bornite and pyrite, and elsewhere hematite and magnetite occur. Coal, magnesite and asbestos are also reported. C. A. S.

Gold deposits of the Ogayu mine. M. Watanabe. *J. Japan. Assoc. Mineral., Petrol. Econ. Geol.* **15**, 97–109

(1936); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 779.— These consist of katathermal pneumatolytic deposits at the contact of diabase dikes with granodiorite, and contain quartz with Au-bearing mispickel and chalcocite, passing into tourmaline-bearing veins further down. C. A. S.

Magmatic gold-copper deposits of the Sanmaeyama mine, Japan. M. Watanabe. *J. Japan. Assoc. Mineral., Petrol. Econ. Geol.* 18, 10–22, 57–68(1937); 19, 280–92 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 758–9.—The ore body consists of plagioclase, diopside, titanomagnetite and magnetic pyrite as products of first crystn., followed by hornblende and chalcocite, the whole in a fine-grained gabbro. The hornblende is an autometamorphic transformation product of augite, partly accompanied by quartz, often poikilitically intergrown. Magnetite and magnetic pyrite are displaced by chalcocite, which often shows sepn. of cubanite, and younger ilmenite. C. A. S.

Some minerals of the (Italian) empire. Enrico Abbolito. *Ricerca sci.* 10, 1099–1106(1939).—Au occurs at Ad Nepas (Eritrea) as a concentrate from the weathering of pyritiferous quartzitic schist; the Au was apparently in solid soln. in the pyrite. Quartz veins traversing chloritic schist in Domiscioba carry Au in assocn. with pyrite and Cu minerals. A Fe-Mn mineral from Monte Ghedem carries up to 57.47% Mn. O. W. Willcox

Silver ores of the Hassei mine. M. Watanabe. *J. Japan. Assoc. Mineral. Petrol. Econ. Geol.* 16, 185–94 (1936); 17, 119–26(1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 801.—Tertiary schists are intimately penetrated by shoots and impregnations of galena, sphalerite, tetrahedrite, polybasite, quartz, barite and witherite. The witherite partly penetrates the barite indicating an increased concn. of CO_2. The deposits are epithermal. C. A. Silberrad

Geology of the Upper Harz lead-zinc lodes. Ernst Becksmann. *Z. prakt. Geol.* 46, 106–11, 127–32 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 237–40.—The order and times of deposition and relative positions of these ores, and of the accompanying vein filling materials, the origin of which is hydrothermal and connected with a granite intrusion, is discussed in detail. C. A. Silberrad

Origin of lead and zinc ores in Rauschenberg district near Inzell (S. E. Bavaria). Joseph Knauer. *Abh. geol. Landesunters. bayer. Oberbergamt.* No. 30, 3–15(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 357.—These ores are mainly limited to the space between 2 great faults. They are probably of epigenetic origin and are of metasomatic formation filling hollow spaces resulting from orogenic disturbances, the mineralizing solns. coming from above, so that the ores will probably become poorer in depth. It seems probable that other similar deposits may be found in the neighborhood. C. A. Silberrad

"Spark-ore" from Bleiberg. O. Friedrich. *Carinthia* II, 128, 30–2(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 248.—Microscopic examn. of a polished section of spark-ore shows fragments of yellow to brown dolomite and grayish calcite in a groundmass of fine-grained dolomite and galena, the latter sometimes penetrated by spears of barite. Pyrite and marcasite were also observed. The sphalerite is always very bright, frequently of conchoidal fracture and occasionally intergrown with the galena. It is occasionally accompanied by an isotropic material which is possibly fluorite. Mineralization probably followed the brecciation. C. A. Silberrad

Central Germany as source of ores in old Germany. Wilhelm Witter. *Germanen-Erbe* 1, 24–6(1936); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 734–5.—Occurrences of native Cu, with malachite and azurite, and of Sn-Cu alloys point to the Vogtland as the probable source of the earliest Cu and bronze. C. A. Silberrad

Geology of Stripa iron ores. Per Geijer. *Sveriges Geol. Undersökning Avhandl.* No. 28, 43 pp.(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 358–9.—The Stripa mine, 47 km. north of Örebo, yields some 300,000 tons of ore (banded Fe quartzite) annually, about ⅔rds. contg. 50% Fe with 0.001% P, the remainder 42% Fe and 0.011–0.015% P. The chief surrounding rock is leptite: dikes of amphibolite and granite-aplite intersect the deposits. 1 The leptites have the compn. of granite and are recrystd. eruptives and tuffs; gneisses and hälleflinta also occur. The banded Fe-quartzite is composed of specular iron ore and quartzite in thin alternating bands, resp. 4–7 and 3–4 cm. thick in green skarn, magnetite occurs sparingly in porphyroblasts 1.5 cm. across. The main body of ore is 16–17 m. thick with a few inclusions of leptite. A 2nd ore-body lies below. The deposit was probably formed by 2 chem. pptn., perhaps from hot springs, and probably as alternating layers of hematite and SiO_2 alternating with acid tuffs. C. A. Silberrad

The iron ore deposits in Manchoukuo. The iron ores of Tohendo iron ore beds located at Rorei Dairishiko and Hachidoko. Tosio Sudo. *Rept. Inst. Sci. Research Manchoukuo* 3, 317–70(Abstract in English 17–18) (1939).—The Rorei Fe ore deposit in Tohendo, Manchoukuo, and about 30 kilometers northwest of Tinko is classified 3 as a shallow sea deposit showing irregular enrichment (Fe 60%) on Utai cryst. dolomitic lime. The Dairishiko deposit is about 10 kilometers southwest of Tinko and is an irregular mass of goethite with parallel beds of Utai dolomitic limestones contg. hematite, chlorite, pyrite, chalcopyrite and Zn blende, with some dolomite and quartz veins. The Hachidoko deposit is 8 kilometers northwest of Hachidoko and is an Fe ore bed at the basal portion of Sinan quartzite, classified as a shallow sea deposit. This 4 deposit is composed largely of a quartz-hematite sandstone contg. quartz, hematite, orthoclase, plagioclase and microcline, cemented with sericite. H. E. Messmore

Iron ore deposits of E. Sudetenland. E. Bederke. *Z. Berg- Hütten-u. Salinenw. deut. Reich* 86, 481–7(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 803.—The Fe ores form lenticular deposits in diabase tuffs, and consist partly of silicious, partly of oxidized material. One de-5 posit consists mainly of magnetite (about 50% Fe), the other of hematite (59–63% Fe) contg. resp. estd. totals of 2 and 1.6×10^6 tons. There is a remarkable parallelism between the formation of magnetite and the degree of metamorphism. C. A. Silberrad

Magnetite in the region of Jequié, Bahia. O. H. Leonardos. *Mineração e metallurgia* 3, No. 14(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 402–3.—A preliminary examn. indicates extensive deposits of magnetite in 6 probably metamorphosed Archaean sediments, possibly amounting to several million tons, and contg. some 65% ore, in this region. Being within 80 km. of the sea it is likely to be of economic value. C. A. Silberrad

French limonite deposits. V. Charrin. *J. usines gaz* 56, 537–9(1939).—Limonite occurs in France mostly in the departments Gard and Herault. The former has been worked extensively, the limonite is, however, mixed with clay and with hematite and some pyrite, hence is not very 7 suitable for use in the gas works. Extensive production has taken place recently in the Marc valley, the layer is from 2 to 10 m. thick. The objection to many of the limonite deposits is that at greater depths they change to hematite or pyrite. A promising territory is in Vaucluse, gas-works limonite also has been recovered at Béhobie in southwest France. B. J. C. van der Hoeven

The nickel deposits in the North of Finland (Petsamo). Legraye. *Rev. universelle mines* 16, 61–2(1940).—Geographical conditions and geol. formations are described. 8 The Ni minerals occur in Precambrian rocks and are composed of pyrrhotite, pentlandite, chalcopyrite, magnetite and silicates; the pyrrhotite carries the Ni and Cu. The deposits vary in thickness from 2.5 to 20 m. The Ni content varies from about 3.0 to 6.5% according to depth, the Cu content from 1.3 to 3.11%. The estd. capacity in this region is about 220,000 tons. M. Hartenheim

The nickel-silicate ore deposits of the Orsk-Khalilovo region. D. G. Ul'yanov, G. S. Gritsaenko, G. A. Krutov, E. A. Petrova and M. G. Shishulina. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) No. 118, 8–122(in English, 123–5)(1937).—The ore bodies are confined to the almost completely serpentinized ultra-basic rocks, mainly harzburgites; they are closely connected with fissures filled with quartz-ferruginous matter. The Ni minerals, chiefly garnierite with some kerolith, are

assocd. with the later generations of quartz and chalcedony. Carbonatization, a later process, produced intense replacement of quartz and serpentine. Later still a superficial nontronitization process enriched the Ni in the upper portions of the deposit. The minerals of the 2 ore deposits, Khalilovo and Akkermanovka, are described (in the Russian part) from the following points of view: morphology, phys. and optical properties, x-ray measurements; chem. compn.; thermal analysis. D. W. Pearce

Tin deposits of the Black Hills, South Dakota. E. D. Gardner. *U. S. Bur. Mines, Circ.* **7069**, 78 pp.(1939). C. L. B.

Materials of the Yakutian expedition of the Institute of Economic Mineralogy. I. Geology and metallogeny of the northeastern part of the watershed of the Allakhyuna and Yudoma rivers. N. I. Zaitsev, F. A. Zakharkin, M. A. Minakov and M. Ya. Stolyar. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) No. **113**, 6–63 (in English, 64–5)(1936).—Tin ore deposits in veins are related to the granodiorite intrusions; 2 types are distinguishable: the oxide type (pneumatolytic) has the paragenesis Sn, Li, Be, F, W, As, S, Cu and Fe; the sulfide type (hydrothermal) has the paragenesis Sn, S, As, Fe, Zn and Pb. Most important are quartz-fluorite and quartz-sulfide (arsenopyrite) veins. The richest among the latter contain 3–4% of stannite. Mo mineralization is also present. **II. Geological explorations in the upper Tyra region and along the route across the Verkhoyansky and Kolymsky ranges.** N. D. Sobolev and P. I. Egorov. *Ibid.* No. **114**, 5–84(in English, 85–8)(1937).—Cassiterite is assocd. with the granodiorite of Dybinsk. In the Kysal-Tass region Sn was found in veins of the following types: pyrrhotite (0.04%), Pb pyrite (0.21%) and Pb arsenopyrite (0.92%). In the Russian part many analyses are reported. D. W. Pearce

Tin-tungsten mineralization at Mawchi, Karen states, Burma. J. A. Dunn. *Records Geol. Survey India* **73**, 209–37(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 777.—A large granite mass has penetrated metamorphosed argillaceous schists, sandstone and limestone. It contains veins of aplite-pegmatite and tourmaline-quartzite, with streaks of tourmaline, cassiterite, wolframite and scheelite. The granite, especially the orthoclase, is much kaolinized, and the biotite chloritized; muscovite is abundant and contains Li. Fluorite, topaz, cassiterite, calcite and other pneumatolytic-hydrothermal minerals occur. Twenty-seven workable occurrences of Sn and W are known. The order of sepn. has been tourmaline, wolframite, cassiterite, (beryl, phenakite, molybdenite), quartz, mispickel, pyrite, sphalerite, (stannite, chalcocite, bismuthinite), calcite, scheelite, lepidolite and chlorite (the rarer minerals are bracketed). C. A. Silberrad

Scheelite in skarns of the eastern slope of the Kuznetsk Ala-Tau. E. F. Ziv. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) No. **145**, 4–158(in English, 159–61)(1939).—See *C. A.* **32**, 4109[8]. D. W. Pearce

Childs-Adwinkle mine, Copper Creek, Arizona. T. H. Kuhn. *Arizona Bur. Mines Bull.* **145**, 127–30(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 778.—The ore body occurs in a crush zone in granodiorite, and is composed of 2 elliptical pipes, 90 × 50 and 70 × 30 m., which in depth diminish or ramify, probably uniting lower down —they are at present known to 280 m. They contain a breccia of granodiorite, largely transformed into chlorite-sericite, cemented together by a mass of quartz, orthoclase, biotite, calcite, pyrite, molybdenite, bornite and chalcocite. In depth molybdenite diminishes, Cu ores increase. In 5 years 3000 tons MoS_2 and 2200 tons Cu with some Au and Ag have been obtained. C. A. S.

Manganese in the Czywczyn hills (Eastern Polish Carpathians). Roman Krajewski. *Inst. géol. Pologne Bull.* **2**, 1–26(French summary 25–7)(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 360.—The deposits consist of carbonates, silicates and oxides and contain on an av. Mn 30, Fe 8 and SiO_2 23%, and are estd. to contain 10,000 tons. They are a prolongation of the Rumanian deposits, and are contact deposits along a zone of disturbance in gneisses and schists. C. A. Silberrad

Rare and nonferrous metals; cobalt-bearing ores of the South Ural. G. A. Krutov, M. A. Mamedov and D. G. Ul'yanov. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) **147**, 5–19(1939).—The results of a survey of Co-bearing Ni and Mn deposits in the region, carried out by the Inst. in 1934–1937, are reviewed and tentative methods for the recovery of Co by complex treatments of the ores are discussed from tech. and economical viewpoints. Chas. Blanc

Joachimstal, the birthplace of radium. H. Schneiderhöhn. *Umschau* **42**, 951(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 243–4.—The ore deposits here are connected with a granite mass. They consist of a large no. of small veins which form 3 zones: the uppermost the richest Ag ores; the middle, Co-Ni and Bi-As; the lowest, the U—pitchblende with quite subordinate galena, sphalerite, pyrite and chalcopyrite, with hornstone, dolomite and some fluorite. The dolomite has been reddened by radioactive action and the fluorite colored a dark-violet and given an unpleasant smell by dispersed Ca and F ions, resp. The enclosing schists have been silicified and impregnated with pitchblende. C. A. Silberrad

Uranium ore on the Goten. G. Konjarov. *Trud. podz. bogat. i min. ind. Bulgarija* **8**, 236–44(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 789–90.—The deposit occurs 200 m. below the summit of the Goten 7 km. from Buhovo (20 km. N. of Sofia) in a zone of contact metamorphism caused by the intrusion of eruptives into clay slate. The ores consist of (1) torbernite, dark-green tetragonal crystals, d. 3.4–3.6, H 2–2.5, n_ω 1.598, n_ε 1.592, pleochroic. Compn. $Cu(UO_2)_2(PO_4)_2.12H_2O$, loses $4H_2O$ at 45°; (2) Metatorbernite I, emerald green, tetragonal, compn. $Cu(UO_2)_2(PO_4)_2.8H_2O$, contains Ra, U:Ra = $1:3.3 \times 10^{-7}$; (3) Metatorbernite II, canary-yellow, rhombic, compn. as of (2), double refraction strong, n 1.657 and 1.740 and (4) limonite, in places weathered to ocher. It is estd. that there is in all some 25,000 tons of ore. Origin: The area was the scene of vigorous hydrothermal action in Silurian times resulting in kaolinization and formation of siderite, galena, stibnite and hematite. As temp. fell, but kept still above 65°, limonite was formed and last of all the U ores. C. A. Silberrad

Minerals of the Tsumeb ore deposits (S. W. Africa). W. Klein. *Allg. Z. Windhuk* Sept. 23–24, **1938**; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 255–6.—A brief account of the minerals found in the mines at Tsumeb, and the levels at which each mainly occurs. They include ores of Cu, Pb, Zn, Ag and V. C. A. Silberrad

The lodes of Neu Bulach in the Württemberg Black Forest. Manfred Frank. *Württ. Jb. Statistik u. Landeskd.* **1936/37**, 102–13(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 237.—A detailed account of the Neu Bulach lodes. Of these the most important is a Bi tetrahedrite, with which occur emplectite, chalcopyrite and siderite, and in the secondary cap-formation limonite, turgite, arseniosiderite, cuprous manganese (lampadite), azurite and malachite, and more rarely erinite, olivenite, mixite and pharmacosiderite. A little auriferous pyromorphite gave hopes (unfulfilled) of paying Au. In the upper parts of the veins barite occurs, but in depth this is replaced by quartz. The adjacent bunter-sandstone is strongly silicified and impregnated with ores. The ore content rapidly decreases in depth. The origin is hydrothermal. C. A. S.

Preliminary note on metal occurrences in the region of the curvature of the eastern Carpathians. T. P. Ghitulescu. *Bull. sect. sci. acad. roumaine* **21**, 73–80(1938–39) (in French).—The region is at the intersection of the Carpathian and the ancient Variscan ranges, and the metallogenetic zone is a continuation of that of eastern Transylvania. The deposits, found in the districts Buzău, Râmnicul-Sărat, Putna and Trei Scaune, contain chiefly pyrite, sphalerite and galena with minor amts. of Cu, Au and Ag, the gang minerals being quartz, calcite, barite and rhodochrosite. The largest deposits yet found are near

Plešu. Here some marcasite and pyrrhotite are also present. Two partial analyses of ore are given. M. F.

Recent hydrothermal ore formation. G. Vasil'ev. *Trud. podz. bogat. i min. ind. Bulgarija* **8**, 227–33(1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 780–1.—Hot springs yielding some 1470 l./min. at 50–59.2° occur along a line of fault between tertiary trachyte and intrusive rhyolite. The water contains 1.6131 g./l.—predominantly SO_4^{--} with some Na^+, K^+ and HCO_3^- and at least 0.05% Fe ion, which is deposited as limonite in fissures or as hematite deeper. Pyrite is also being deposited as shown by the state of coins and metal objects found in the spring. These show deposits thereof at the rate of about 1 mm. in 700 years. C. A. Silberrad

Paleozoic deposits on the headwaters of the Lower Tunguska and Chona rivers, and in the Njuja basin. V. G. Vasil'ev. *Bull. soc. naturalists Moscow, Sect. géol.* **16**, 53–72(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 520–2.—Elaborate discussions on the dolomitization and silicification of some of the deposits are given. C. A. S.

Magnesite in Jugoslavia. G. Petunnikov. *Rud. i Top. Vesnik* **9**, 42/43, 44/45, 46/47, 48/49(1937); **10**, 1/2, 3/4, 5/6, 7/8(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 260.—Numerous deposits of magnesite occur. The veins are up to 10 m. wide and sometimes extend for 2.5 km., though as yet but comparatively little worked. They mostly represent gelatinized magnesite, and when cryst. there is usually so much $CaCO_3$ that it almost becomes dolomite. Analyses of 5 samples give $MgCO_3$ 93.22–97.08; $CaCO_3$ 0.06–2.88; R_2O_3 0.33–1.52; SiO_2 0.14–3.30; H_2O 0.15–0.50. Material contaminated with serpentine contains more $MgCO_3$ than that which is quite or nearly free therefrom. C. A. Silberrad

Kieselguhr of the Vardar Banat. L. Marić. *Bull. serv. géol. roy. Yougoslav.* **7**, 333–6(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 503.—Several deposits of infusorial earth occur here consisting of diatoms with admixt. of clay, limonite, muscovite, feldspar and quartz, and in one case considerable NaCl and perhaps $MgSO_4$. Analyses of 2 samples are given. C. A. Silberrad

Geological features of some deposits of bleaching clay. G. Austin Schroter and Ian Campbell. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1139**, 31 pp.(1940).—Mineralogy and properties are reviewed briefly with chem. analyses of 9 typical bleaching clays. Origin and classification are discussed at length. Com. deposits formed by the action of ascending thermal solns are rare. Deposits formed in place (authigenic) by cold meteoric solns. are the commonest. 85 references. Alden H. Emery

The Shabry deposit of talc-magnesite stone. B. P. Ural'skiĭ. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) No. **129**, 5–67(in English, 68–9)(1938).—The talc-magnesite rock is a vertically dipping body in mica-chlorite-quartz schist; gradual transitions from it to serpentinites are observed. Besides talc and magnesite (in nearly equal amts.) chlorite, serpentine, magnetite, hematite, chromite and pyrite are present. Analyses of the material from different parts of the deposit as well as of the genetically related pyroxenite and serpentinite are given (in the Russian part). Hydrothermal emissions from granite intrusions are believed to have been the metamorphosing agents. *Bricks* are sawed directly from the quarry faces; some material is also sepd. into talc and magnesite; the former has only about 2% Fe_2O_3 + FeO; the latter is suitable for the production of refractory brick. D. W. Pearce

Agalmatolite deposits and diaspore pebbles of Mitsuishi. Koziro Kinizuka. *J. Japan. Ceram. Assoc.* **47**, No. 567, Suppl. 1–13(1939).—This article relates to the geology of Mitsuishi agalmatolite mine, production and distribution at the mine, the origin of the agalmatolite, the mechanism of the formation of the deposits, and Medamaishi (diaspore pebbles). (1) The Mitsuishi agalmatolite (Roseki) is a soft but compact aggregate of pyrophyllite, kaolinite, diaspore, unaltered rock, pyrites and alunite. It is the most important raw material of agalmatolite refractories. It is classified into 17 classes whose pyrometric cone equiv. varies from cone 41 to 28. (2) The mine consists of liparite, felso-liparite, pyrophyllitized liparite, shale, pyrophyllitized shale, and agalmatolite. (3) As to the origin of the deposits, K. advanced a new theory that the agalmatolite was formed by the action of gases and heat on lumps of liparite and especially shale caught in magma of felso-liparite. It is likely that magma of the liparite and especially that of felso-liparite had contained a considerable amt. of F, since liparite deposits with well-developed fluorspar veins have been found not very far from Mitsuishi. Diaspore seems to be the end product of the metamorphosis, pyrophyllite and kaolinite being intermediate products. (4) "Medamaishi" or diaspore pebbles are contained in the agalmatolite. Their diam. varies from 30 cm. to 3 mm. It is claimed that they were formed by the pneumatolytic action on the small pieces of rocks which had been produced on the lumps of shale and liparite caught in the magma of felso-liparite. S. Kondo

Phlogopite deposits of south Madagascar. Alfred Lacroix. *Compt. rend.* **210**, 273–6(1940).—These deposits have now been worked at Betroka to a depth of 80 m. Below layers (1), sometimes 60 m. thick, whence everything sol. has been leached out by surface water, and (2), usually only a few m. thick, where the minerals so removed have been deposited, is (3) the intact zone, where the original minerals exist unattacked. These are all distinguished by the size of their crystals, and consist of green or grayish diopside in crystals up to 10 cm. across; red and yellow calcite sometimes 15 cm. across; and phlogopite, of which one crystal measured 3.5 × 1.2 m. In smaller amts. there occur: fluorapatite in blue or green crystals up to 70 cm. in diam.; anhydrite up to 20 cm.; fluorite in masses weighing up to 20 kg.; deep-green spinel of which one mass weighed 4 kg.; allanite in blocks weighing up to 2 kg., rich in Ce and La, with small quantities of Pr, Nd, Sm and Th, which last explains its radioactivity. *Seyrigite*, a new mineral in broken golden, translucent quadratic crystals up to 7 cm. across, occurs embedded in calcite and enveloped in a mixt. of quartz, opal and sepiolite; its luster is vitreous to adamantine, d. 5.484, and in compn. it is intermediate between scheelite and powellite, a sample contg. 26.01% MoO_3. Enormous crystals of sphene, together with a little molybdenite, pyrrhotite, pyrite, chalcopyrite, scapolite and anorthite are also found. C. A. S.

The Sysertsky deposit of anthophyllite-asbestos. V. V. Arshinov, B. P. Ural'skiĭ and A. P. Bocharova. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) No. **125**, 4–88(in English, 89–92)(1937).—The anthophyllite seems to have been derived from enstatite (itself derived from orthopyroxene dike or schlieren masses) at high temp. and pressure by action of H_2O and CO_2 from granite magma intrusions. The paragenesis is compared with that of the Idaho and Georgia (U. S.) and Finnish deposits. The rocks with long-fiber asbestos form irregularly shaped vein-like bodies of coarsely cryst. texture. Data are given (in the Russian part) on: tensile strength (before and after various heat-treatments); heating curves (early dehydration and later oxidation of FeO takes place), comparisons in this respect are made with chrysotile and crocidolite; acidproof qualities (MgO is more readily dissolved than is FeO); treatments with NaOH and KOH and with various salts were also studied. Up to 550° the strength of anthophyllite asbestos decreases slowly and to a small extent; beginning at 550° the strength exhibits a sharp decrease and at 700° is practically lost. The decrease at 550° is simultaneous with the increase in the intensity of the oxidation of FeO. Analyses of the various rocks and minerals are given; lower content of (Mg, Fe) and higher OH in the short-fiber asbestos is due to the partial alteration to talc and to the formation of asbestine. D. W. Pearce

Sulfate in salt deposits of N. W. Argentine. S. D. Villareal. *Univ. nacl. Tucuman, Cuadernos min. y geol.* **1**, 30–5(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 272.—The amts. of Na_2SO_4 in *saline waters* or deposits in Belén, Tinogasta and the Santa Maria Lake are, resp., 0.466, 0.122 and about 15%. The large amt. in the last-named case probably accounts for the liver troubles of the inhabitants who use water from the lake. C. A. S.

Barite at Radis, near Kaade (N. W. Bohemia). W. R. Zartner. *Lotos* **86**, 81–3(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 251–2; cf. *C. A.* **33**, 2853[6]. —Hematite and sporadic pyrolusite occur in hornblende and barite veins 0.5–1.5 m. wide in gneiss near Radis, 8 km. northwest of Kaade. The barite is yellowish to brownish, and contains $SrSO_4$ 1.05, $CaSO_4$ 0.05, $Al_2O_3 + Fe_2O_3$ 1.0, SiO_2 10.34 and H_2O 0.6%. It is usually fine-grained and compact, but in places crystals up to 2 cm. long occur which have grown on massive violet-blue fluorite. Elsewhere the hematite is accompanied by earthy Mn, and in one place there is a bed of white kaolin. The deposit is pneumatolytic-hydrothermal. C. A. Silberrad 1

Barite vein in granite in the Spessart near Aschaffenburg. Rudolf Mosebach. *Senckenbergiana* **17**, 218–23 (1935); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 790–1.—The position and origin of this barite are discussed, and it is thought to have resulted from a pneumatolytic-hydrothermal process, rather than, as once suggested, from the meeting of ascending and descending solns. C. A. Silberrad 2

Gas measurements over petroleum deposits. G. Selzer and R. Weber. *Petroleum Z.* **34**, Nos. 39–40, 11–13 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 301.—An app. is described showing the concn. of CH_4, etc., over petroleum deposits, whereby "isogas" lines (i. e., lines of equal gas concn.) are detd., whence combined with gravity detns., information as to oil distribution and geological structure is deduced. The method was applied only where the oil was at a depth of 60–90 m. C. A. S. 3

Earth structure and earth origin. K. F. Mather. *Science* **89**, 65–70(1939).—An address. B. C. P. A. 4

Structural and magmatic processes in the isostatic layer. Malvin G. Hoffmann. *Bull. Am. Assoc. Petroleum Geol.* **23**, 1320–51(1939).—Formation of magmas is discussed. Pressure increases the crystn. temp. of minerals and the viscosity of glass. Erosion may reduce pressure and heat may be developed through movement. Thus erosion may initiate fractional crystn. and magma formation. The rest magma will become increasingly acidic, the percentage of mineralizers will grow and eventually intrusion and extrusion will occur until the whole body is solidified. Alden H. Emery 5

Pegmatite dikes of the Bridger Mountains, Wyoming. Thad G. McLaughlin. *Am. Mineral.* **25**, 46–68(1940).—Pre-Cambrian black hornblende schist, probably of igneous origin, has been invaded by large masses of granite followed by 2 sep. intrusions of pre-Cambrian granite pegmatite dikes. The older dikes follow a joint set paralleling the schist foliation; they contain approx. 70% microcline and 30% quartz. The younger dikes follow a jointing across the foliation of the schist; hydrothermal solns. have partially replaced the original dike minerals, pptg. muscovite, lepidolite and petalite, then cleavelandite which replaced much petalite, followed by tourmaline, beryl, garnet, columbite and tantalite. Banding paralleling both strike and dip occurs in several dikes, apparently due to rhythmic pptn. C. H. Hale 6

Feldspar-free rocks connected with the sakenites. Alfred Lacroix. *Compt. rend.* **210**, 193–6(1940); cf. *C. A.* **34**, 621[1].—The sakenites are locally accompanied by rocks contg. no feldspar, but consisting of pyroxene or amphibole with one or more Al- and/or Mg-contg. minerals. These include the sapphirinites, composed almost entirely of sapphirine with sometimes a little spinel, and an alteration product thereof related thereto somewhat as antigorite is to peridotite in serpentinization; several varieties of spinellite, sometimes composed almost entirely of a bluish or more rarely deep-green spinel; and spinel- and sapphirine-pyroxenes and a sapphirine-amphibolite, which last consists mainly of a greenish-white amphibole rich in Al_2O_3, belonging to the edenites. Twelve complete analyses are given, showing compns. similar to those of magnesian marls rich in clay, with no trace of any external material, characterized by high Al_2O_3 and CaO content, low SiO_2 and very little Fe, indicating a special class of plagioclasites and pyroxenites. C. A. Silberrad 7 8

Petrography of Baveno granite. P. Gallitelli. *Atti soc. tosc. sci. nat. Pisa, Mem.* **46**(1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 496–9; cf. *C. A.* **33**, 91[6].—A connected and detailed account of the Baveno granite and its constituent minerals and rocks. C. A. Silberrad 9

Nushagak district, Alaska. J. B. Mertie, Jr. *U. S. Geol. Survey Bull.* **903**, 96 pp.(1938).—The geology of the district is described. Chem. analyses of 4 granites and 3 monzonites are recorded. No metal deposits of com. value have as yet been found, but the country is probably mineralized. Au occurs in small quantities at widely-sepd. localities. B. C. P. A.

Volcanic history and petrology of Montserrat with observations on Mt. Pelé in Martinique. A. G. MacGregor. *Trans. Roy. Soc.* (London) **B229**, 1–90(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 525.—After giving an account of the various volcanic phenomena, the eruptive rocks are described microscopically and chemically with 16 analyses, several new. These include analyses of labrador-dacites (of quartz-dioritic, belugitic, and peleitic types) and olivine-basalts (of belugitic and ossypitic types). C. A. Silberrad

Ejectamenta of the Laacher See area (Eifel). IV. Sanidinites. Georg Kalb and Maximiliane Bendig. *Decheniana* **98, A**, 1–11(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 470–2.—The sanidinites, the formation of which is to be ascribed to a phonolitic magma, are classified as (1) nosean-, (2) aegirine- and (3) scapolite-sanidinites, or (1) nephelite-syenite-pegmatite, (2) fenite and (3) huttenbergite. They are described in detail with complete analyses. Finally the subterranean processes (8 stages of pyrometamorphism) leading to their formation are briefly described. C. A. Silberrad

The labrador-andesites of Crni Vrh and Ješevac in Šumadija (Central Serbia). B. Dimitrijević and M. Ilić. *Bull. serv. géol. roy. Yougoslav.* **7**, 291–312(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 503–4.—The massif of Crni Vrh and Ješevac consists in its lower part of gray to reddish dacite and andesite with andesine phenocrysts; the upper and central portion of dark, rarely reddish andesite with labradorite. These labradorite-andesite rocks are classified in 3 types according as the phenocrysts are labradorite and hornblende; labradorite with a little hypersthene; or augite with a little biotite and hypersthene. They are described in detail, and their origin, probably from the dacite-andesite, discussed. C. A. Silberrad

A new rock in the Altvater hills (Sudeten Gebirge). J. Wilschowitz. *Firgenwald* **11**, 155–6(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 488–9.—The new rock resembles basalt; it is of lamellar structure with a yellowish gray weathered surface, a metallic ring, and when breathed on emits a clayey smell. It contains sporadic crystals of calcite 1 mm. across, with pyrite and magnetic pyrite. The microscope shows dark biotite and laths of plagioclase. The dark color is due to ore. There is a little diopside, usually transformed to chlorite. It appears to be an altered kersantite. C. A. Silberrad

Eruptives of the Raška region. (Mid-Serbia). M. Ilić. *Bull. serv. géol. roy. Yougoslav.* **7**, 217–90(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 504–5.—These rocks are the result of 4 magma movements; resulting in (1) Palæozoic peridotites, chromitite, picotite and gabbros; (2) post-Senonian diorites, syenites, albitites and granite; (3) Neogene outpourings of andesine-andesites and dacite and (4) probably still younger labrador- and bytownite-andesites. Microscopic detns. of the various constituents divide the rocks into 8 classes, the first of which includes rocks contg. no felspar; these form about half the whole and consist of olivine, enstatite, diopside with subordinate pigeonite and accessory spinel, magnetite, and in places chromite, which last also occurs in nests 1–3 m. across in serpentinized peridotite. Secondary minerals are serpentine, forming 37–95% of the rock. The other classes are characterized by the predominance, resp., of gabbros, diorite, albite-syenite, albitite, granite, andesine-andesite, and labrador- and bytownite-andesite, all of which are described in considerable detail. C. A. Silberrad 10

An inclusion in the basalt-lava of Daun (Eifel). H. Winter. *Decheniana* **97, A,** 47–50(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 472–3.—Complete analyses of the basalt-lava, d. 3.120, and of the inclusion, a felso-quartzite, d. 2.567, contg. 90.64% SiO_2 are given. C. A. Silberrad 1

Physiography, chemical composition and genesis of the gabbroid massif of Dren-Boula (S. Serbia). M. Tajder. *Rad jug. ak. znan. i umjet Mat. pr. r.* **268**, 1–54(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 501–3.—The various rocks found in this massif are described, with complete analyses and parameters of many (verlite, troctolite, several gabbros including olivine-, uralite- and amphibolite-gabbros, diorites and diabases). Their mutual relations are discussed, and their formation by differentiation from a common original magma illustrated by diagrams. C. A. Silberrad 2

Structural petrology of the schists of Eastern Otago, New Zealand. F. J. Turner. *Am. J. Sci.* **238**, 73–106 (1940).—Oriented sections have been cut and subjected to petrofabric analysis. Alden H. Emery 3

Metamorphism and igneous action. H. H. Read. *Advancement of Sci.* **1**, 223–51(1940).—An address. D. W. Pearce

Kibara formations, Katanga. G. Mortelmans. *Bull. soc. belge géol., paléontol. hydrol.* **49**, 163–70(1940). These consist of phyllites, quartzites, schists, etc., exhibiting epizonal and mesozonal metamorphism resulting from granitic intrusions which also caused in places stanniferous mineralization and the formation of pegmatites, aplites, tourmalinites, etc., which are described. C. A. S. 4

Geology and petrography of the Rottenmanner and Solker Tauern, (Styria). II. Wieseneder. *Mineralog.-petrog. Mitt.* **50**, 273–304(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 484–6.—Descriptions of many rocks are given, including an intermediate gneiss the original material of which was a biotite-rich gneiss, the biotite contg. many pleochroic halos around crystals of allanite; a group of garnetiferous mica schists in which occur amphibolites, mica schists and various biotite gneisses. The group has been variously metamorphosed with formation of garnet amphibolite, staurolite- and kyanite-contg. rocks and tremolite marble. There is also a serpentine stock which probably originated independently. C. A. Silberrad 5

Tourmaline-zoisite rock from Loh-Oeolo, Java. Cath. M. Koomans. *Leidsche Geol. Meded.* **10**, 104–9(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 522.—The rock consists of 16–19% colorless to pale-green tourmaline, 35–37% phlogopite, 39–44% zoisite and some muscovite. Its probable origin is discussed and thought to be connected with a neighboring diabase dike contg. lenses of Mg-rich limestone. C. A. Silberrad 6

The metamorphic rock of Siedlec near Krzeszowice (Poland). A. Bolewski. *Ann. soc. géol. Pologne* **14**, 1–44 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 492–3.—The rock is a much decompd. quartz-porphyry similar in compn. to a potash-rich porphyry west of Cracow. Compared to fresh rock, K_2O and SiO_2 are remarkably high and H_2O low. A sample placed in a 1% soln. of K_2CO_3 at 100° absorbed K_2O. Immersion in 5% K_2CO_3 followed by immersion in hot H_2SO_4 showed the stability of the newly formed constituent, which appears to be a feldspar. In the clayey by-product formed at the same time the ratio $SiO_2:Al_2O_3 = 4.41$; alkali $Al_2O_3 = 0.045$, total H_2O 9.54%; m. p. about 1700°. No kaolin was observed. There were 0.3–1.5% of zircon, rutile, tourmaline and apatite, and 7.1–10.1% of isotropic material. C. A. Silberrad 7

Geology of eastern Crna Gora (Kara Daga) (South Serbia). M. Luković. *Bull. serv. géol. roy. Yougoslav.* **7**, 1–27(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 506.—These mountains run north and south to the north of Skoplje (Uskub). The north and northeast portions consist of gneiss, mica schist and granite-gneiss with veins of aplite and pegmatite. The south and southwest portion is much more varied; phyllite, quartz, marble, magnetite-chlorite, diabase-chert, peridotite, gabbro, granite, syenite, andesite and dacite all occur. Various ores are worked in or near Lojane. Chromite and stibnite of pneumatolytic-hydrothermal origin occur, connected with the dacite-andesite. At the contact with the cryst. schists Ni and Mn ores, magnetite and veins bearing Fe and Cu, and impregnations thereof in quartzite and finally pyrite impregnations 10–20 m. in width occur in diabase-chert. C. A. Silberrad 8

Sedimentary siliceous rocks, hornstone and the flint problem. J. Kühnel. *Z. deut. geol. ges.* **91**, 207–31 (1939).—The possible origin of hornstone and flint is discussed. B. C. P. A. 9

Is a thermal hypothesis of flint formation possible? W. Wetzel and D. Wirtz. *Z. deut. geol. ges.* **91**, 231–6 (1939).—Kühnel's views (preceding abstr.) are criticized. B. C. P. A.

Tubular siliceous concretions in gravels at the base of the Upper Eocene. Marcel E. Denaeyer. *Bull. soc. belge géol., paléontol. hydrol.* **49**, 161–2(1940).—Certain specimens labelled as fulgurites, found in gravel at Saint Gilles (Brussels) consist of 3 generations of spherulites and fibers of chalcedony, the oldest outside. It is considered that they are not fulgurites but originated as tubes formed by Polychaetae, which acted as geodes favoring crystn. of the SiO_2, the chalcedony being of secondary origin. C. A. Silberrad

Koppite-carbonatite and koppite-marble from Schelingen-im-Kaiserstuhl. H. Metschke. *Ber. Naturforsch. Ges. Freiburg i. B.* **36**, 28–56(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 225–6.—Koppite occurs here much more extensively than at first thought, being present in approx. const. proportion in all the cryst. limestone of the neighborhood. It is now worked as a source of Cb. In these cryst. limestones there were formed by pneumatolytic addn., at the contact with essexite, koppite, apatite, magnesioferrite, etc. A somewhat similar product, termed koppite-carbonatite, has been similarly formed in a tephrite-breccia. C. A. Silberrad

Microstructure and composition of "cone-in-cone" of Lower Devonian metamorphics from Morhet (Belgian Ardennes). Marcel E. Denaeyer. *Bull. soc. belge géol., paléontol. hydrol.* **49**, 119–25(1940).—The microscopic examn. of the section of cone-in-cone previously macroscopically described (*Ibid.* **48**, 408(1938)) is now described. It consists of veinlets of phyllite more or less regularly arranged, and phenoblasts of biotite irregularly scattered in a fine groundmass of quartz and ilmenite. Analysis gives SiO_2 69.29, Al_2O_3 4.16, Fe_2O_3 1.12, FeO 5.57, MgO 2.29, CaO 1.58, Na_2O 0.95, K_2O 1.44, TiO_2 5.51, P_2O_5 0.19, $H_2O +$ 7.38, $H_2O -$ 1.11; or quartz 33.01, biotite and phyllites 33.64, ilmenite and magnetite 12.11, other 0.40, $H_2O -$ 1.11. No conclusion as to the origin of the structure is suggested. C. A. Silberrad

The nature and the age of the basement deposits of the Sarmatian found in a drill core at Horodnic-Bucovine (Rumania). M. G. Filipescu. *Bull. sect. sci. acad. roumaine* **21**, 30–4(1938–39) (in French).—Overlying the limestone is a bed of friable sandstone at depths 1114 to 1156 m., and a bed of anhydrite at depths 1054 to 1114 m. The mineralogy of the sandstone (quartz, feldspar, zircon, ilmenite, etc.) indicates volcanic activity or igneous extrusion in the region shortly after the limestones were laid down. Michael Fleischer

The cost of soil in rocks and time. W. H. Twenhofel. *Am. J. Sci.* **237**, 771–80(1939).—The amt. of rock and the time to form 1 ft. of soil from various types of rock under different conditions are discussed. Alden H. Emery

Physical and mineralogical description of loess from Tschak am Wardak (Afghanistan). R. Köhler and J. H. Hellmers. *Z. prakt. Geol.* **46**, 207(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 435–6.—The loess is a yellowish gray porous, friable material, contg. 22.3% $CaCO_3$, with a negligible amt. of org. matter, and (dried at 105°) 1.6% H_2O. Mech. and mineralogical analyses are given showing it to be rather a loess-loam. C. A. Silberrad

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Metallurgy in industry. Carl T. Hewitt. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 118-23(1940).—An address. Leopold Scheflan

Rare metals and minerals. Zay Jeffries. *Mining and Met.* **21**, 10-12(1940).—A review of 1939 developments in Be, Co, Li, Mo, Pt, Pd, Ru, Rh, Ra, Se, Te, Ta, W, U and V. Co is being used in armament. Mo is being recovered from Cu ore. Pt-alloy spinnerets are being used for producing glass fiber. Large Pt crucibles are being 4 used to produce large crystals for optical uses. Pt-clad Ni is now available. Pt-alloy electrodes in aircraft sparkplugs resist erosion and are free of fouling. Pd photographic printing papers have great permanence. Ru is twice as effective as Ir in hardening Pt. Se and Te are being added to Cu alloys to improve machinability. Alden H. Emery

Principles of flotation. IX. Influence of the anion on air-mineral contact in presence of collectors of xanthate type and its consequent influence on differential flotation. Ian W. Wark and Keith L. Sutherland. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1130**, 23 pp.(1939); cf. *C. A.* **33**, 9220⁸.— The influence of certain anions, viz., carbonate, chloride, nitrate, formate, acetate, propionate, tartrate, phosphate, silicate and ferricyanide, on flotation by K Et xanthate was studied. Except for carbonate, 6 phosphate, silicate and ferricyanide, all were added as Cu salts replacing the usual $CuSO_4$ addns. Apart from its influence on pH, Na_2CO_3 has no influence on contact in the absence of heavy metal salts. It has an effect in the presence of a cation (Cu) with which it forms a ppt. Even in the presence of a Cu salt, if xanthate concn. is sufficiently high and temp. is not excessively low, Na_2CO_3 has no specific effect. An amt. of xanthate slightly in excess of the stoichiometric equiv. of the Cu present maintains a 7 standard "contact curve" whatever the nature of the anions present and whatever the temp. If xanthate concn. is reduced and (or) the temp. is lowered, Na_2CO_3 induces departures from the standard type of curve. Formation of a second or "island" area of noncontact is favored by (1) low xanthate concn., (2) high concn. of Cu salts, (3) low temp. or (4) high concn. of Na_2CO_3. Either in the presence or absence of Cu salts, lime may be substituted for NaOH without altering the contact curves. Presence 8 of lime means almost complete absence of CO_2, consequently data on CO_2 free systems should be used at plants in which lime is used as the alkali. Differential flotation is often based upon the more-ready formation of islands of noncontact with some minerals than others and on the differentiation that persists as the islands expand into alk. regions. Pyrite is more susceptible to their formation than sphalerite which is more susceptible than chalcopyrite. Cleiophane is as susceptible to island formation as sphalerite but marmatite is not as susceptible. Pyrrhotite is not as susceptible as pyrite. Probably conditions suitable for the sphalerite-pyrite sepn. will serve for marmatite-pyrrhotite. Sphalerite is coated with a Cu-bearing activation film in the island region of noncontact. Galena carries a similar film, but it is responsible for depression. Arsenopyrite more closely resembles sphalerite than pyrite in island formation. Substitution of other Cu salts for sulfate leads to more-ready depression within the island region of noncontact. In order of increasing depressant action on sulfide minerals they are sulfate, nitrate, chloride, tartrate, propionate, acetate and formate. Island formation begins at pH 6-7; some cyanide also is required. As depressant conditions are intensified, the island increases in size and may fuse with the upper region of noncontact. It may expand until depression is possible in the absence of cyanide. The growth of the island is more regular at 35° than at 10°; this may be due to nonattainment of equil. at the lower temp. Island regions of noncontact are obtained with other collectors of the xanthate type—Aerofloat 25 and mercaptobenzothiazole Addn. of a relatively high concn. of NaCl has little influence on the size and position of the island when CuCl is used. The island region of noncontact is primarily due to xanthate deficiency arising from its more or less pptn. by the Cu salt. Thus a small concn. of cyanide ions may prevent adsorption of the xanthate and in certain instances there may be enough hydroxyl ions to prevent adsorption. The products of decompn. of Na_2CO_3 solns. induced by the growth of a mold are harmful in pyrite flotation. Alden H. Emery

Experiments in flotation of sulfide-hübernite ores. F. N. Belash and O. V. Pugina. *Tsvetnye Metal.* **1939**, No. 7, 72-5.—Ore contg. quartz, muscovite, fluorite, hubernite, calcite, galena, pyrite and chalcopyrite was subjected to flotation with oleic acid and sodium oleate as frothers and collectors and water glass and $K_2Cr_2O_7$ as depressors. With wet grinding to minus 100 mesh the results were unsatisfactory because of considerable flotability of quartz. With dry grinding better results were obtained, the loss of WO_3 in tails being 2 to 2.5%. Water glass was found to act as depressor of hübernite; $K_2Cr_2O_7$ gave better results. In further expts. $K_2Cr_2O_7$ was substituted by ammonium dichromate. Expts. in wet grinding were made using porcelain, steel and cast iron mills and balls in various combinations. Best results were obtained with porcelain mills and balls. Apparently Fe ions from steel mills and balls activate the quartz and float it. Cast iron was found to be still more harmful than Mn steel. The use of porcelain in industry is impracticable; therefore the authors tried chem. treatment of the pulp. Addn. of soda to grinding mills prevents transfer of Fe ions into the pulp and prevents activation and flotation of quartz. The method was also found helpful in the flotation of Mo concentrates. Best results are obtained with solid:liquid ratio of 1:4; ratio of 1:2 is acceptable. Recovery of W is 95% with coeff. of extn. of 25 and consumption of 700 g. sodium oleate per ton. Expts. also showed that for economy green soap can be substituted successfully for 9 Na oleate and oleic acid. B. N. Daniloff

Effect of the percentage of solids in pulp on the time of flotation and the efficiency of the apparatus. V. D. Benenson. *Tsvetnye Metal.* **14**, No. 3, 63-9(1939); *Chimie & industrie* **42**, 821.—Tests carried out on Cu-Zn ores, Zn-Pb ores and pyrites-quartz mixts. showed that the efficiency of the flotation app. is inversely proportional to $1 + \delta R$, where δ is the d. of the ore and R the ratio of liquid to solids in the pulp. The time of flotation depends

on the d. of the pulp; the relative speed of flotation is max. for a d. corresponding to $R = 2.5:1$. A. Papineau-Couture

Oxygen-free flotation. II. Further experiments with galena. S. F. Ravitz. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1147**, 7 pp.(1940); cf. *C. A.* **28**, 1309[1].—Products of oxidation are not necessary for flotation of galena. Galena cleaned with a soln. of NH_4Cl and HCl could be floated with no reagent, terpineol alone or Et xanthate alone, the rate increasing in the foregoing order. H_2O_2, $K_2Cr_2O_7$ and particularly starch were strong depressors for cleaned galena in the absence of a collector. At moderate concns. Na_2S, $Pb(NO_3)_2$, Na arsenate, Na_2HPO_4, acetone, EtOH, petr. ether and Et_2O had no effect on flotation of cleaned galena in the absence of a collector. Na arsenate and Na_2HPO_4 depressed aged galena in the presence of 0.05 lb. K Et xanthate per ton. No contact could be detected between an air bubble and cleaned galena in H_2O. Alden H. Emery

Experimental flotation of Washington magnesite ores. J. B. Clemmer, H. A. Doerner and F. D. DeVaney. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1148**, 10 pp (1940).—A selectively mined, high-grade ore analyzing MgO 42.76, CaO 2.0, R_2O_3 1.6, SiO_2 3.6 and insol. in HCl 4.8% was treated in a pilot plant. With cationic-type reagents (DLT 699, Emulsol 903-L and du Pont 243), 1 lb. per ton, SiO_2 was removed by flotation to give a product contg. less than 1% SiO and less than 2% CaO with 85% recovery of MgO. Caustic starch and tannic acid assisted in the flotation of siliceous minerals. Low-grade mine rejects analyzing MgO 34–40, CaO 5–9, R_2O_3 1.6–2.1, and insol. 6–9% were treated by a 2-stage process. Siliceous minerals and calcite were removed with cationic-type collectors, then magnesite was floated from dolomite by usual soap-flotation methods. A broad range of magnesite products, well within specifications for refractory magnesite, was obtained. Alden H. Emery

Ore concentration and milling. E. W. Engelmann. *Mining and Met.* **21**, 36–9(1940).—Improvements in grinding, gravity sepn., cyanidation, flotation and dust control in 1939 are reviewed. Use of rod mills between intermediate crushing and coarse grinding is increasing. They eliminate dusting and the closed-circuit operation of fine crushers and the product is suitable for secondary mills. Low-level mills increase grinding capacity. Several new float-and-sink processes are in operation; halogenated hydrocarbons are used in the du Pont process, a heavy suspension of $PbSO_4$ at Mascot, Tenn., and ferrosilicon suspensions on the Fe ranges; subsequent treatment is described. A new process provides simultaneous soln. and adsorption of Au. Peru Sb-Au ores are roasted at 600–700°F. and the calcine is washed with H_2O, then lime water to remove Sb prior to cyanidation. Atomization of cyanide pulp in a tank is superior to mech. or air agitation. Cleaning of mineral surfaces prior to flotation is beneficial. Alaska Juneau has improved grade of concentrate by intermittent conditioning with starch for C depressant. Use of jigs in grinding circuits is increasing. Dispersing table pulps enables effective handling of smaller material. Deep flotation cells are being installed. Procedures at 2 Cu mills for recovering Mo concentrates are sketched. Alden H. Emery

Ore-testing studies of the ore-dressing Section. A. L. Engel and S. M. Shelton. *U. S. Bur. Mines, Rept. Investigations* **3484**, 34 pp.(1940).—Results of lab. tests on 21 ores are presented. They include 9 Mn ores from Ala., Calif., Colo., Ida., Mo., Nev. and New Mex.; $PbCO_3$ ore from Nev.; Sb ore from Calif.; anorthosite feldspar from Minn.; crude white lead from Mo.; Calif. talc.; chromite ore from Calif.; Ohio SiO_2 sand; sphalerite-barite ore from Mo.; and Cu ores from Colo. Lab. tests of fluorspar-mill tailings were carried into pilot-plant stage. Alden H. Emery

Reduction of purple ore. Yutaka Huzii and Satou Taniguti. *Tetsu-to-Hagane* **26**, 1–13(1940).—The ore contains approx. Fe 60, SiO_2 10, S 1–2, P 0.02 and Cu 0.1–0.25%. An attempt was made to reduce this ore to a product that could be used in place of steel scrap in steel manuf. Sponge iron and iron lumps can be made in a rotary kiln, tunnel kiln, reverberatory furnace, Detroit elec. furnace, etc., by reduction with CO and solid carbon at very high temps. However, S is not eliminated; hence the product is used only in basic elec. furnaces. M. Ishida

Humidification of cyanide muds with aqueous solutions of wetting agents, as a means of overcoming their pulverulence. M. E. Lipets. *Tsvetnye Metal.* **13**, No. 12, 29–30(1938); *Chimie & industrie* **42**, 486.—Preliminary treatment of cyanide muds with aq. solns. of various wetting agents (sulfonic acids, soaps, naphthenic derivs.) of suitable concn. prevents pulverulence of the muds which produces considerable loss of Au. A. P.-C.

Precipitation and refining practice at Wright-Hargreaves mill. V. C. Lindsay. *Can. Mining Met. Bull.* No. **333**, 39–43(1940).—After clarification in Merrill sluicing clarifying presses, the pregnant soln. is deacrated under vacuum. Au is pptd. with Zn dust. Zn consumption is 0.50 oz. per ton of soln. A typical ppt. analysis (dry basis) is Au 43.20, Ag 6.38, Cu 12.26, Te 3.08, Zn 7.62, Pb 0.44 and insol. 15.00%. To this are added borax glass 28, niter 30, SiO_2 17, NaCl 10, lime 7, soda ash 5 and Fe_2O_3 7%. Refinery plant practice is described. Costs of clarification and pptn. are $0.063 per oz. of Au and of refining $0.030. Alden H. Emery

Low-grade ore at Young-Davidson mine. N. J. Southern. *Can. Mining Met. Bull.* No. **333**, 44–55 (1940).—This Au ore after crushing and grinding is classified and tabled. The coarse concentrate contains most of the free Au and sulfides. Au extn. is by cyanidation. The flow sheet is given. Alden H. Emery

Observations on the mineralogy and treatment of auriferous rocks of the Black Reef series from the New Machavie mine. J. J. Frankel. *J. Chem., Met. Mining Soc. S. Africa* **40**, 115–33(1939).—The ore contains carbonaceous material that interferes with Au extn. by cyanidation. Results of a careful study of the mineralogy of the ore are presented. Satisfactory extn. of Au should be obtained by grinding and removal of free Au and some pyrite on corduroy tables followed by flotation and fine grinding and cyanidation of the flotation concentrates. Alden H. Emery

Some recent uses of charcoal as a gold precipitant in conjunction with flotation. M. W. Von Bernewitz. *Eng. Mining J.* **141**, 43–7(Mar., 1940).—Instances are noted from operations and lab. work conducted in the U. S. A. and abroad. W. H. Boynton

Reduction of iron ores under pressure by carbon monoxide. Michael Tenenbaum and T. L. Joseph. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1134**, 18 pp.(1939).—The most rapid rate of reduction was obtained with H. Rate was increased 40% by doubling pressure. With pure CO, the rate was about 1/4 that with pure H. Doubling the pressure increased rate of reduction by 23%. Dilu. of CO with N to form bosh gas lowered reduction rate by 1/2. Doubling the pressure increased the rate about 20%. Substitution of 8.2% CO_2 for an amt. of CO in bosh gas reduced rate still further. Pressure is most effective when applied to strongly reducing gases, rather than to those approaching equil. compn. Theoretical considerations are discussed. Alden H. Emery

Effect of the nitrogen content of reduced gases on the reduction of oxides of iron. M. M. Lelbovich and I. P. Lampsakova. *Metallurg* **13**, No. 9, 61–6(1938); *Chimie & industrie* **42**, 276.—A study of reduction at progressively increasing temps. (400–900°) showed that increasing the proportion of reducing agent in the gas lowers the reduction temp. The effect of gas compn. is most marked at 600–700°. A. Papineau-Couture

Metallurgy of copper. P. D. I. Honeyman. *Mining and Met.* **21**, 16(1940).—A review of progress in 1939. The new smelter at Hurley, New Mex., is described briefly. Alden H. Emery

Metallurgy of lead. R. G. Bowman. *Mining and Met.* **21**, 13–14(1940).—A review of 1939 developments in Pb smelting, refining and use. Wider and longer sintering machines are being used. An ignition device for sintering

machines that saves 60% in oil consumption has been installed at Trail. Sn is being removed from Pb with gaseous Cl. Alden H. Emery

Platinum deposits of the Goodnews Bay District, Alaska. J. B. Mertie, Jr. *U. S. Geol. Survey, Bull.* **910-B**, 115–45(1939). E. H.

Platinum. H. W. Lohse. *Can. Mining J.* **61**, 161–2 (1940).—Canada leads the world in Pt production, where it is obtained from the treatment of Ni-Cu matte at Sudbury, Ont. Uses of Pt, and other metals of the 8th group in the periodic system, are named. W. H. Boynton

Deleading zinc concentrates at the Pend Oreille mill. C. A. R. Lambly and Frank R. Milliken. *Eng. Mining J.* **141**, 29–31(Mar., 1940).—Operations at the Pend Oreille Mines & Metals Co. plant near Metaline Falls, Wash., treat 750–850 tons of ore daily. Flotation of the Pb is accomplished in two 10-cell Union Iron Works flotation machines using Aerofloat 31 as a collector, and no reagents for depressing the Zn are needed. Pb tailings are conditioned with $CuSO_4$ then floated in two 12-cell Denver machines and three 10-ft. Southwestern cleaners. Pine oil and Et xanthate are used in the Zn circuit except when the feed is high in pyrite, in which case xanthate is replaced by Na-Aerofloat. Pb rougher concentrates are double-cleaned and the Zn rougher concentrates triple-cleaned. Tailings from the primary Zn cleaner are fed to an 8-ft. (2.44 m.) cone classifier. The classifier sands are reground in closed circuit with the classifier, the overflow being returned to the Zn conditioner. Final concentrates are filtered in disk-type filters. A recovery of 92.1% of the Pb in a 62.3% concentrate was obtained from heads assaying 1.65% Pb and 4.46% Zn. The cyanide used averaged over a 2-month period 4–5 lbs. per ton of concentrate treated, and the flotation feed was maintained below a crit. d. of 22% solids. The flotation is accomplished in a 6-cell Weinig 30-in. (76.4-cm.) flotation machine using the 1st cell as a single-stage cleaner. The flowsheet, aside from the deleading unit, follows standard practice for floating Zn-Pb. Flowsheets are shown, including one for the present deleading unit. W. H. B.

Metallurgy of zinc. H. R. Hanley. *Mining and Met.* **21**, 15–16(1940).—A review of 1939 developments in metallurgy of Zn. Production per retort in horizontal-retort distg. plants continued to increase. Ag-Pb alloy is now standard for anodes at most electrolytic Zn plants. Cast Pb anodes coated with electrolytically deposited Pb by the Betts process (cf. *C. A.* **4**, 2071) are giving satisfactory results in stabilizing these electrodes at 1 plant producing cathodes of high-grade Zn. A. H. E.

Roasting of Beattie concentrate. F. R. Archibald, F. J. Martin and A. T. Koenen. *Trans. Can. Inst. Mining Met.* **42**(in *Can. Mining Met. Bull.* No. **332**), 608–31 (1939).—Arsenic in flotation concentrates resulted in poor cyanide extn. More consistent and higher extn. is obtained if As and S are eliminated under certain controlled conditions of time, temp. and gas concn. (*a*) SO_2 and H_2O vapor concn. are regulated through early stages of treatment in the roasters, wherein the charge is brought to a temp. within the range 750–850°F. The concn. of gas should be such that slow surface oxidation is prevented. (*b*) Inlet of air is regulated and such a condition is maintained that the roast proceeds steadily and without local surface cooling below roasting temp. At this stage, the SO_2 concn. is maintained by the roasting charge. (*c*) Toward the end of active roasting, temp. is raised and may reach 1200°. During this and subsequent cooling, free access of air is desirable. (*d*) If roasting is unduly prolonged by excess SO_2 concn. and if the temp. becomes excessively high, magnetite and other ferrites will form and extn. will not be good. Slimes also may be contributory. An extensive lab. investigation of the effect of different variables on roasting is presented. A. H. E.

Roasting of sulfides with air enriched with oxygen. IV. Oxidation of copper concentrate. N. P. Diev, Yu. V. Karyakin and A. G. Loshkarev. *J. Applied Chem.* (U. S. S. R.) **12**, 655–61(1939); cf. *C. A.* **33**, 6204[8].—The oxidation of Cu concentrate (a sulfide complex) proceeded at 500° according to a mechanism related to the oxidation of individual sulfides. At the same temp. desulfurization proceeded with a considerable velocity and reached 81–81.5% in 52–78 min. A relative acceleration of the oxidation in the presence of various concns. of O (over that in the presence of air) was independent of temp. and on av. equal to 59 for 10% O, 123 for 30% O, 136 for 40% O, 144 for 50% O and 149% for 66% O, with an exception for 50 and 66% O at 500° where relative accelerations were 185 and 194%, resp. V. **Oxidation of zinc concentrate.** *Ibid.* 661–8.—All S can be removed from the Zn concentrate at 1100° in 36–44 min. The velocity of oxidation increased by 11–93% with an increase of O concn. to 60%, depending on temp. The final step of desulfurization at 500° was independent of the O concn. VI. **Oxidation of sulfide ore.** *Ibid.* 668 73(in French, 673 4).—The oxidation of sulfide ore proceeded in the same way as that for individual sulfides. At 700–1100° an increase of desulfurization was observed at 40% O concn.; above this concn. the desulfurization increased but slightly. At 500° the effect of O concn. on desulfurization was greatest. The size of ore grains (within 1-3 mm.) had no effect on oxidation velocity. 23 references. A. A. Podgorny

An apparatus for determining thermomagnetic behavior of slags, and some preliminary results obtained with it. B. A. Rogers and K. O. Stamm. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1133**, 11 pp.(1939).—A convenient app. for detg. thermomagnetic behavior of slags and metal oxides is described. It is based on the principle that if a ferromagnetic substance such as a slag is placed in a nonuniform magnetic field it experiences a force that tends to move it into the region of max. field strength. A Frantz magnet with an isodynamic field was employed for supplying the nonuniform magnetic field. Detns. of force on the sample with a magnetic balance were rapid, convenient and as accurate as desired. The use of the app. is illustrated with measurements on Fe oxides. Alden H. Emery

Structure of the slags in the basic open-hearth process. W. Bischof. *Arch. Eisenhüttenw.* **13**, 325–32(1940).—Expts. are described and discussed which were undertaken to clear up the relations between the changes in the slag (chem. and phys.) during the melting process and its appearance. Four different groups of slags could be distinguished: (1) slags with a creased, wrinkled surface, (2) with smooth surface, (3) with a mesh-like surface, showing fine cracks, and (4) slags with irregular surface. These groups differ by their CaO and SiO_2 content: group 1 is observed only at high SiO_2 and low CaO contents, group 2 comprises slags of about 42% CaO and 20% SiO_2, group 3 is found around 45% CaO and 18% SiO_2, and group 4 are ladle slags. MnO, FeO and Fe_2O_3 occur mainly in the more acid slags, an effect on surface quality could not be established. P_2O_5 is said to favor formation of group 3 but this is not at all certain. Appearance and structure bear a certain relation with the fluidity as found by Herty, *et al.* (*C. A.* **29**, 3275[8]). The Mn reaction between slag and steel melt and the Mn utilization was found to increase with increasing CaO content up to a ratio of $CaO/SiO_2 = 2$, when a slight decrease begins. Seventeen references. M. Hartenheim

Reverberatory melting of slags. V. S. Sokolov. *Tsvetnye Metal.* **1939**, No. 7, 88–92.—Exptl. melting of slags with the purpose of recovering metals therefrom was tried at the Molotov Copper Smelter. The slags contained about 1.4% Cu, 0.8–1.4% Pb, 8.5% Zn and 25–9% FeO. By the addn. of 10–15% of coal and 10–15% of FeS to the charge a recovery of 90–1% of Cu, 83–7% Zn and 94% Pb is claimed; however, troublesome formation of large solid skulls on the furnace hearth was encountered. The skulls consisted mostly of Fe and Cu. In order to prevent the reduction of Fe and the formation of skulls it was necessary to add S to convert the Fe to FeS or to dissolve it in FeS. Exptl. lab. melts with varying amts. of coal and pyrite added showed that the reduction of the metals is directly related to the amt. of coal; Fe is reduced along with these. Tests made at the smelter with addn. of 12% coal and 17% pyrite produced very good results with only

a negligible amt. of reduced Fe in the skull. The loss of S amounted to 23%, the remainder going into mat as FeS. B. N. Daniloff

Melting difficultly fusible charges in reverberatory furnaces. D. M. Yukhtanov. *Tsvetnye Metal.* **13**, No. 12, 47–51(1938); *Chimie & industrie* **42**, 659–60.—The use of difficultly fusible charges lowers the efficiency of metallurgical furnaces and increases the fuel consumption. These disadvantages can be overcome by incorporating with the charge a small proportion of a powerful fluxing agent: fluorspar, Na and K salts, etc., which lower the m. p. of the slag. A. Papineau-Couture

Thermal work in reverberatory furnaces. I. D. Semikin and M. D. Shabli. *Tsvetnye Metal.* **14**, No. 3, 71–85 (1939); *Chimie & industrie* **42**, 821.—The chief reason for the low efficiency of existing reverberatory furnaces lies in their insufficient thermal power. The optimum thermal power of these furnaces is 50–60 million cal. per hr., or about 300,000 cal. per hr. per sq. m. of hearth area, corresponding, for a 180-sq.-m. furnace, to a production of 1400 tons of Cu per 23 hr. with a heat consumption of 800,000 cal. per ton. It is necessary to modify the heat balance of the furnaces so as to obtain complete and intense combustion of the fuel over as short a distance as possible. A. Papineau-Couture

Furnace for melting Al—description of its construction and operation. T. A. Booth. *Metal Ind.* (London) **56**, 168–70(1940).—The immersion heating is carried out with internally-(gas) fired radiant tubes of a new nonferrous alloy (compn. not stated). The alloy tubes are very resistant to molten Al. Two cu. ft. of town gas is consumed per lb. of Al. Sizes from 100 lb. to 5 tons are obtainable. F. W. Fink

Method for the manufacture of low-cost aluminum. Paul Drossbach. *Chem.-Ztg.* **63**, 606–8(1939).—A modified blast furnace with combined elec. and coke heating (operating temp. 2200°) is charged with Al-, Fe- and Si-bearing ores; e. g., phyllite and iron ore. The Fe-Al-Si alloy is refined in a special furnace at 1400° resulting in pure Al and 20% Fe-Si. The latter alloy can be sold, or further refined into steel. Economic and thermodynamic considerations indicate that the new method is advantageous. No details of furnaces and operation are given. F. W. Fink

Material, energy and plant requirements in direct extraction [of iron]. Hugo Bansen. *Stahl u. Eisen* **59**, 785–90(1939).—A discussion of costs, with especial reference to salzgitter ores, and in comparison with normal procedures. B. C. P. A.

The manufacture of pig iron in America. Wm. A. Haven. *J. Iron Steel Inst.* (London) Advance copy May, 1940, 43 pp.—Discussion of economics, construction and operation of furnaces for 6 districts each with its own materials: Nova Scotia, Eastern New York State, Youngstown, Chicago, Birmingham, Utah. Numerous illustrations and tables of data are included. F. G. N.

Crystal orientation in silicon-iron sheet. J. T. Burwell. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1178**, 4 pp.(1940).—The component crystals are oriented with a (110) plane in the rolling plane and a (001) axis in the rolling direction. Alden H. Emery

Iron and steel. M. J. R. Morris. *Mining and Met.* **21**, 54–6(1940).—Use of plain C steel has increased as its quality has improved owing to better control at various stages. Lower-alloyed steels are being used in automobiles. Use of steels in aircraft is increasing. Wt. per h. p. has been reduced. Use of stainless and high-tensile low-alloy steels in railroad and other construction has increased. Such steels are demanding better welding practice and more attention to structural design. Even more attention than previously is being given to stainless steels. Use of complex steels is increasing, but as they increase in complexity, addnl. Mn is needed to maintain workability. Use of Cu in deep-hardening steels is increasing. Use of the elec. furnace for steel-making and of induction heating has increased. Alden H. Emery

Dust concentrations in foundries. T. Hatch, C. E. Williams and B. G. Dolin. *N. Y. State Dept. Labor, Ind. Bull.* **18**, 89–95(Feb., 1939); *U. S. Pub. Health Eng. Abstracts* **20**, IHS, 5(Feb., 1940).—From a survey of 12 foundries it is concluded that dust concns. should be kept below 30,000,000 particles per cu. ft., and can be reduced to ½ this figure with ordinary care. C. R. F.

Relation of ingot surface as reflected by mold wall surface to billet or bloom surface. T. J. Woods. *Iron Age* **145**, No. 8, 37–9(1940).—The relation of mold condition to the surface of direct rolled billets and blooms was studied on 61 heats of hot-topped medium-carbon and alloy steel deoxidized to give fine grain. Tarring improves the surface of the product in a new mold. When the mold becomes fire checked (which happens between 65 and 100 pours) the tar collects in the crevasses of the mold and reacts with the metal to form blow holes. It is then easier for the original ingot surface to be scaled off in the soaking pits with resulting poor surface of the product. F. G. N.

Effect of elevated temperatures on steels and mixtures. A report on progress of research. H. L. York. *Foundry Trade J.* **62**, 59–62(1940).—Several siliceous sands with bentonite and fireclay bonds, and a natural molding sand were investigated to det. their behavior at high temps. The following conclusions were reached: (1) Neither the bentonite nor the fireclay-bonded sands as a group are unaffected by heat shock. (2) Some sand mixts. were sensitive to heat shock and cracked at comparatively low temps. Other mixts. were unaffected by heat shock and developed the same strength under shock test conditions as when treated slowly. (3) The strength of the sand mixts. tested increased with temp. up to the point at which the bond began to fuse. At higher temps. the strength decreased rapidly and approached zero at the temp. of complete fusion of the bond. (4) The fireclay-bonded sands in every case reached their max. strength on slow heating at a higher temp. than the corresponding bentonite-bonded sands; the difference averaged 75°. (5) (*a*) The bentonite-bonded sands disintegrated on cooling from any temp. between 900 and 1200°. (*b*) The fireclay-bonded sands became very fragile but did not disintegrate on cooling from any test temp. (*c*) Sands bonded with either bentonite or fireclay developed a high strength on being cooled from the temp. at which the bond became completely fused. (6) The total deformation of the specimens at the max. load did not increase appreciably with temp. until the bond began to fuse. (7) The hot strength at a given temp. in the plastic zone was always higher for the fireclay-bonded sands than for those bonded with bentonite. I. Hartmann

Antipiping compounds and their influence on major segregation in steel ingots. E. Gregory. *J. Iron Steel Inst.* (London) Advance copy, May, 1940, 10 pp. Analysis of drillings and S prints from blooms are shown from ingots with (I) ordinary feeder head, (II) feeder head covered with antipiping compd. or asbestos, and (III) same as II and then after poured. The height of the center of segregation and the extent of segregation increased from I to III. S segregation is most pronounced. The extreme is 0.228% S from a ladle analysis of 0.030% S. The basic cause of major segregation may be the formation of a partially miscible liquid complex. The rate of demulsification depends on casting conditions, but complete sepn. of the 2 liquids cannot take place in practice. Delayed freezing favors coalescence and sepn. of the particles of the conjugate liquid solns. Differential freezing is a cause, but not the complete explanation of segregation in steel ingots. Only with delayed freezing in the head did the position of the major segregate approach the base of the primary pipe. F. G. N.

High-strength cast steels. Georges Delbart. *Trans. Am. Foundrymen's Assoc.* **47**, 179–94(1939).—See *C. A.* **34**, 1601⁶. J. E. D.

Metals in drilling. XI. Rotary drilling bits. W. L. Nelson. *Oil Gas J.* **38**, No. 36, 45, 52(1940); cf. *C. A.* **34**, 1954⁶.—The metallurgy of bits, reamers, cutters, etc. **XII. Hard facing materials.** *Ibid.* No. 39, 50.—The metallurgy of facing materials, inserts and rods. W. Andrew Wright

Elements of the petrographic study of bonding clays and of the clay substance of molding sands. Ralph E. Grim. *Trans. Am. Foundrymen's Assoc.* **47**, 895–908 (1940). E. H.

Metals as engineering materials. C. H. Desch. *Foundry Trade J.* **62**, 149–51(1940).—Three lectures dealing with (1) historical development of metals; (2) metals as engineering components; mech. properties; (3) structures of metals; transformation of austenite; alloy steels; development of powder metallurgy. I. Hartmann

Metallurgical researches with the electrostatic ultramicroscope. H. Mahl. *Z. tech. Physik* **21**, 17–18(1940).—Microphotographs are shown for *Fe oxide* and *ZnO smoke*, *rust* from electrolytic Fe and a rail, and *oxide films from Al and electrolytic Fe*. The film from the Fe shows about 10^8 pores per sq. mm., while that from the Al shows substantially no pores. J. B. Austin

Measuring metallic luster. Richard Springer. *Z. Elektrochem.* **46**, 3–13(1940).—Based on American research, especially on work of B. Egeberg and N. E. Promisel, S. defines the measurement of luster: to arrange a given series of specimens of different lusters in the same order as one would do visually and with approx. the same spacing between samples. It shall be used to standardize metal surfaces, to study metal-plating baths, as a specification for metal orders, to define the polishing of the parent metal in metal plating, to study surface changes due to corrosion in air and to study different pickling and polishing compds. A Pulfrich photometer (binocular) is used perpendicular to the surface to be measured while the light is hitting the surface at 45°. One eye is focused on the surface the other on a standard $MgCO_3$ plate. Standard filters define the readings, 0–2% being the highest degree of brightness. All measurements are taken for max. and min. and by 3 individuals. 74 surfaces were studied mostly Cu and brass, pure, with surface treatment, with nickel plating, Ni-Cr plating, Cr-, Ag-, Cd-, Zn- and Sn-plating. Different methods and degrees of polishing for parent metal and plating were compared. The classification checks surprisingly well with the visual judgement which is given. J. M. Noy

The melting point of metals. V. N. Svechnikov. *Metallurg* **14**, No. 3, 28–36(1939).—The m. p. of metals is related to the av. coeff. of thermal expansion by the equation $(V_f - V_0)/V_0 = 0.08$, where V_f is the vol. at the m. p. and V_0 is the vol. at 0°K. Coeff. of expansion curves for Cu, Al, Ag, Au and Pt exhibit a sharp break at 70–190°K. and correspond very closely to the at. heat capacity curves for the same elements. H. W. R.

Some notes on liquid shrinkage and contraction. E. Longden. *Foundry Trade J.* **62**, 81–2, *84(1940).—A lecture discussing soundness of castings and the factors influencing it, as the constitution of the metals, gases, etc.; densifiers and chills; contraction and distortion of alloys. I. Hartmann

Gating and pouring temperatures in nonferrous foundry practice. J. Laing. *Foundry Trade J.* **62**, 99–101(1940).—L. discusses the correct gating methods and pouring temps. in manuf. of castings of gun metals, P bronze, yellow brass, Al bronze, Al alloys and Ni Cu alloys. I. Hartmann

The balanced-blast cupola and fluidity. Wm. Y. Buchanan. *Foundry Trade J.* **62**, 113–14, 133–4, 141 (1940).—The balanced-blast cupola gives higher fluidity than the ordinary type. The Saeger and Krynitsky fluidity test (cf. *C. A.* **26**, 2149) is very useful in foundry work and in research when reasonable precautions are taken in its use; it can be of considerable service in maintaining good fluidity as a precaution against gas-hole defects in castings. Fluidity can be improved by ladle addns., in particular addn. of graphite. Si has an adverse effect on fluidity. The effect of S in the presence of normal Mn is not so serious as is generally supposed, and it might be usefully employed as addn. to cast iron when Cr is used. I. Hartmann

Elements promoting graphitization and those retarding graphitization according to their position in the periodic system of Mendeleev. Yu. A. Tomin. *Liteĭnoe Delo* **9**, No. 6, 29–32(1938); *Chem. Zentr.* **1938, II**, 3361.—The elements that retard graphitization are divided into 2 groups: the Fe group (Cr, Mn, V, Mo and W) and the C group (O, S, B, Sn and Sb). The Fe group forms a characteristic cross in the periodic table with Cr as the element in the middle having the greatest retarding action on graphitization. The C group is less characteristic and the regularity in the periodic system not so pronounced at first glance. The elements that promote graphitization can also be divided into a C group (P, Si, Al, Mg) and an Fe group (Ti, Ni and Cu). M. G. Moore

Absorption of graphite in hardening and tempering cast iron. J. E. Hurst. *Metallurgia* **21**, 91–4(1940).—Data are given to prove that cast Fe contg. no combined C can be hardened by quenching. Properties of some quenched and tempered irons are given. J. L. Gregg

Autogenous hardening of cast iron and malleable cast iron. Gottfried Kritzler and Franz Roll. *Z. Ver. deut. Ing.* **84**, 148–50(1940).—See *C. A.* **33**, 2085³. J. E. D.

Precipitation hardening of copper-silicon-beryllium and copper-manganese-beryllium alloys. M. I. Zakharova. *Metallurg* **14**, No. 2, 80–6(1939).—Cu alloys contg. Be 0.5 and Si 2.75–4.00% or Be 0.5–1.0 and Mn 2.76–10.4% after quenching from 800° can be aged at 300–350° to a Brinell hardness of 330. The hardening process is accelerated by cold working after quenching. H. W. R.

Precipitation hardening of supercooled austenite in high-speed steel. I. I. Bornatskiĭ. *Metallurg* **14**, No. 3, 56–64(1939).—Steel contg. C 0.75, W 17.4, Cr 4.2 and V 0.62% was heated to 900–1350° and cooled in air. Dilatometric measurements showed that the temp. of the austenite-martensite transformation was lowered if the steel was heated to higher temp. owing to the increased C content of the austenite. Similarly, specimens were heated to 1300°, cooled in air to 600–700°, held at that temp. for 10 min. to 7 hrs. to permit pptn. of carbides and cooled in air. The transformation temp. was higher in those specimens held at 600–700° for a long time as more carbides were pptd. H. W. Rathmann

Time quenching. John L. Burns and Victor Brown. *Trans. Am. Soc. Metals* **28**, 209–29(1940).—A qual. hardness study of effects produced when the cooling rates of fine-grained S. A. E. 1040 and 1060 steels were interrupted during quenching revealed concentric rings which differ structurally in a typical condition produced. The behaviors of the steels are explained on the basis of transformation shown by the "S" curve. W. A. Mudge

X-ray investigation of the tempering of carbon steel. K. I. Alekseeva and A. P. Komar. *J. Tech. Phys.* (U. S. S. R.) **9**, 1643–8(1939).—Steel (C 0.8%) was quenched from 750° to 15° and then tempered at rising temps. for 30–40 min. at each temp. The intensity of the X-ray lines produced by the faces (110) and (112) increased with the temp. of tempering to a limit reached at 500–600°. The increase is slow between 250° and 300° and near 320°, presumably because of a formation of carbides. J. J. Bikerman

Aging of elastically deformed metal. A. A. Zolotarev. *Metallurg* **14**, No. 4–5, 76–82(1939).—After normalizing at 830° Bessemer rail steel was stressed within the elastic limit over a period of 224 days and changes in impact strength, hardness and elec. cond. were detd. Aging occurred, decreasing the impact strength 25% and increasing the hardness and elec. cond. H. W. Rathmann

Deformation of steel during nitriding. G. F. Kosolapov. *Metallurg* **1938**, No. 11, 88–93; *Khim. Referat. Zhur.* **2**, No. 5, 80(1939).—Steel plates 10 × 3 × 200 mm. were nitrided (*a*) at 520° for 24 hrs. or (*b*) at 500° for 10 hrs., at 600° for 10 hrs. and at 500° for 4 hrs. The increase of the vol. of the nitrided layer was found to be the main cause of deformation. With increase of the temp. of nitriding the elasticity decreased and the plastic deformation increased. Addn. of 1% of Cr increased the hardness after nitriding to 500–600° Brinell, Al acts similarly and addn. of 1% Cr + 1% Al increases the hardness to 1000–2000°. The deformation is greater in steels which show the greatest increase of hardness; C steels with Cr

addns. were much less deformed than were Cr and Al steels. The deformation and the hardness after nitriding are detd. mainly by the nature of the solid soln. of N and steel, i. e., the α phase. W. R. Henn

Gaseous nitrocementation. V. I. Prosvirin. *Metallurg* 1938, No. 11, 84–7; *Khim. Referat. Zhur.* 2, No. 5, 79 (1939).—N accelerates the diffusion of C into iron. Steel or Fe is heated to 800–25° in an elec. furnace and treated alternately with NH_3 (for 1 min.) and CH_4 (for slightly more than 1 min.). The samples are then cooled in water. The microstructures produced resemble the structures of steels obtained by cyaniding. In the nitrocementation process satn. of the solid solns. with C and N must be avoided, because from the moment of satn. the N begins to sep. from the solid soln. in the form of Fe nitrides; this causes brittleness of the nitrocemented layer. N and C in the nitrocemented layer are contained in the solid soln. of the α and γ phases. W. R. H.

Furnaces used in the working of aluminum and its alloys. I. Physical and chemical characteristics of aluminum and its alloys in the hot and problems relative to the construction and use of the furnaces employed. II. Furnaces for fusion. III. Furnaces for reheating, annealing and thermal treatment. A. de Biran. *Rev. aluminium* 15, 1000–1010, 1196–1214(1938); 16, 1546–67 (1939).—A review. C. L. B.

Rapid annealing of steel strip to obtain granular pearlite. N. T. Gudtsov, N. F. Vyaznikov and M. I. Peisikhis. *Metallurg* 14, No. 4–5, 63–75(1939).—Steel contg. C 1.04, Mn 0.25, Si 0.37, S 0.017 and P 0.010% was hot-rolled to 2 × 55 mm. and then cold-rolled to 1.5 × 55 mm. Specimens were then annealed by various methods to a granular pearlitic structure to det. the most rapid method of annealing for subsequent cold rolling. The best procedure was to heat at 780° for 5 min., transfer to Pb bath at 500° for 20 sec. and spheroidize at 700° for 60 min. This gave a tensile strength of 65 kg. per sq. mm. and an elongation of 20%. Steel contg. C 0.67, Mn 0.65, Si 1.45, S 0.016, P 0.007 and Cr 0.37% was best annealed by heating at 870° for 15 min., transferring to a Pb bath at 500° for 2 min. and spheroidizing at 710° for 60 min. This gave a tensile strength of 77 kg. per sq. mm. and an elongation of 17%. H. W. Rathmann

The structural changes in copper effected by cold rolling and annealing. Maurice Cook and T. Ll. Richards. *J. Inst. Metals* 66, No. 859, 1–15(1940).—Pieces of Cu (99.95%) were given 10–97% cold reduction and examd. by x-ray (transmission and glancing) and microscopic methods. Each individual crystal distorted on its own slip planes up to 50% reduction. Material reduced over 50% showed two sets of crystals having preferred orientations. On annealing, no preferred orientation was observed in material given less than 50% reduction. On reductions greater than 50% some of the material recrystd. into two sets of crystals with orientations corresponding to the two textures, while the rest recrystd. into a single preferred orientation. The greater the amt. of reduction, the greater the part of the recrystn. that is of the single preferred orientation type. James W. Poynter

Hot-working of crude iron under pressure. V. Tikhovskiĭ and I. Karlinskaya. *Stal* 7, No. 10, 28–32(1937); *Chem. Zentr.* 1938, II, 3448.—Gray iron contg. C 3.71, graphite 3.27, Si 2.1, Mn 1.3, P 0.145 and S 0.064% could not be pressed but could only be stamped by the use of light hammer blows. Probably gray iron having a lower C content can be more easily hot-worked. In order to prevent the formation of cracks the temp. should be in the neighborhood of the m. p. (1050–60°). Certain changes in structure were observed after hot-working. From this it can be assumed that the mech. properties are also changed. M. G. Moore

Solution potential of cemented iron in acidulated water. Stéfan Procopiu. *Compt. rend.* 210, 219–21(1940).—The soln. potential, V, was detd. by means of 2 cells: Hg|Hg_2Cl_2|KCl.aq, satd.|acid, aq.|Fe(cem.) (giving E volts) and Fe(cem.)|acid aq.|Fe (pure) (giving e volts). Changes with time of cementation, t, and of soln., T, until V becomes that of pure Fe, indicate that a surface-oxidized layer is first removed and then the cemented layer, the thickness (δ) of which, as shown by the loss in wt. of the electrode in time T, is represented by Kt, K depending on the temp. of cementation, C, and increasing therewith, as well as on the time during which it continues; thus for t = 10 min., and C = 900°, δ = 125 μ and for C = 950°, δ = 139 μ, corresponding figures for t = 20 are 164 and 259 μ. The thickness of the oxidized layer is similarly detd. as of the order of 1 μ.

C. A. Silberrad

Antifriction and abrasion-resisting qualities of cast iron. IV. Masahiro Tasaki. *Imono* 12, 25–40(1940); cf. *C. A.* 34, 1287⁶.—The coeff. of friction and the amount of abrasion are parallel to some extent. Abrasion-resistance is best between 2 samples of the same pearlitic cast iron. Cast iron contg. C 3.0, Si 1.3, Mn 0.7, Cr 0.8, P 0.2, S 0.1%, of Brinell hardness 240–60 is recommended.

M. Ishida

The rate of solution of graphite in liquid cast iron. I. N. Bogachev and L. D. Lobacheva. *Metallurg* 13, No. 7–8, 55–8(1938); *Chimie & industrie* 42, 279.—Soln. of the graphite is very rapid at first; then, when there remains in the Fe but a small amt. of graphite (which is a function of the chem. compn. of the Fe and of its original graphite content), the rate of soln. slows down. It can be supposed that Fe_3C is present in the liquid phase; the endothermic reaction of the formation of cementite being reversible, its dissocn. takes place simultaneously; under definite conditions a mobile equil. is reached.

A. Papineau-Couture

The accelerating effect of certain metallic elements on graphitization. H. A. Schwartz, Vincent Fiordalis, John L. Fisher, James F. Shumar and M. J. Trinter. *Trans Am. Soc. Metals* 28, 143–52(1940); cf. *C. A.* 31, 5731⁸.—The graphitization-accelerating effects of Cu and Ni on white cast Fe were detd. to study the mechanism by which metallic alloys alter graphitizing rates. Wt. for wt. the effectiveness of Cu and Ni at 900°F. is closely alike. One % of either metal approx. doubles the rate of an Fe already contg. approx. 0.90% Si; neither element, in amts. up to 1%, greatly affects the soly. of graphite in γ-Fe, Cu has little effect on nodule no. at 1650°F.; Ni has little effect on the nodule no. but increases the no. of very small nodules, and either element increases the migratory rate of C in γ-Fe. The data at 1290°F. are less conclusive. Both elements produce approx. similar acceleration but Cu seems to be effective mainly by decreasing nodule no.

W. A. Mudge

Examination of a wrought-iron cannon of the fifteenth century. A. Pomp and F. Spies. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 22, 1–8(1940).—This museum piece (from Vienna) is built up of longitudinal bars kept together by transverse rings not welded together; between the bars and rings an intermediate layer was found of nonmetallic nature, mostly oxide. The chem. compn. of the outer rings was 0.026% C, 0.06 Si, 0.0 Mn, 0.043 P, 0.008 S, 0.01 Cu; that of the bars 0.01–0.06% C, traces to 0.05 Si, 0.0 Mn, 0.049–0.092 P, 0.006–0.010 S, 0.04 Cu; and that of the intermediate layer 69–7% Fe_2O_3, 2.15 FeO, $Fe_{met.}$ 0.78, 0.72 SiO_2, 0.0 Al_2O_3, 0.048 P, 2.0 S, 0.49 CaO, trace MgO, 0.0 MnO, loss by annealing 14.6%. It seems that the intermediary layer was a cement to fill the interstices between ring and bars, this would account for the high S of the entirely corroded layer. Macro- and microscopic etchings showing the irregular structure are added. M. Hartenheim

Presence of oxygen in cast iron. N. P. Kalashnikov. *Metallurg* 13, No. 2, 104–7(1938); *Chimie & industrie* 40, 896.—O can be present in cast iron in the form of FeO, SiO_2, Mn oxides and their compds., CO and CO_2. To det the total quantity, only the hot extn. method must be used. For gray iron the content varies from 0.002 to 0.015%; for malleable iron, from 0.002 to 0.02%.

A. Papineau-Couture

Chromium-silicon cast iron. A. L. Norbury and E. Morgan. *Foundry Trade J.* 62, 137–41(1940).—A survey of the microstructures, tendency to chill, and air- and oil-hardening capacities of cast irons having Cr con-

tents between 0 and 15% and Si contents between 1 and 11%. The following conclusions are drawn: (1) One % of 69% ferrochromium added to crucible melts increased the Cr content of the resulting cast an av. of 0.6% Cr. (2) Increasing the Cr content stabilized the pearlite and secondary cementite and caused white iron eutectic to replace graphite, but did not cause self-hardening or the replacement of pearlite by martensite. (3) In cast irons of normal total C content, the chill-producing action of 1% Cr neutralized the chill-reducing action of about 1% Si. (4) Cr increased the Brinell hardness and reduced the machineability. In most compns. it increased the mech. strength and reduced the deflection. (5) As the Cr content increased, the white iron eutectic assumed the form of carbide crystals in a ferrite matrix, instead of austenite globules in a carbide matrix. (6) Cr raises the f. p. of the white iron eutectic. I. Hartmann

The α,γ-transformation of iron at high pressures, and the problem of the earth's magnetism. Francis Birch. *Am. J. Sci.* **238**, 192–211(1940).—The change with pressure of the temp. of the α,γ-transformation in very pure Fe was detd. by a dilatometric method to more than 4000 kg./sq. cm. in N and A. The mean value for several different irons for the rate of change above 1000 kg./sq. cm. is $-8.5°/1000$ kg./sq. cm.; at lower pressures, some curvature is found with A as the pressure medium, probably due to small N content of A. The latent heat found from this rate and the change of vol. is about 4 cal./g. α-Fe can be of only limited importance in the earth's magnetism, since its existence is restricted to a thin shell near the surface. Alden H. Emery

Isothermal transformation of austenite in die steels. M. P. Braun and L. D. Khabinskaya. *Metallurg* **14**, No. 3, 71–80(1939).—Steel contg. C 0.60, Si 0.48, Mn 1.60, Cr 0.81, Ni 0.53 and Mo 0.26% was quenched from 800° in a salt bath at 550°, held for 25 min., quenched in oil and drawn for 1 hr. at 550°. With this treatment it was a satisfactory substitute in dies for steel contg. C 0.46, Si 0.33, Mn 0.64, Cr 0.77, Ni 1.59 and Mo. 0.20%. H. W. Rathmann

Steels of special quality for use in the gas industry. P. Thomas. *J. usines gaz* **56**, 430–42(1939).—A review on special steels. They are subdivided into the α and γ types and their structures are discussed. The mechanism of mech. and of chem. destruction is reviewed as well as the effect of high temps. Typical compns. and their useful ranges are given. B. J. C. van der Hoeven

Twenty years of alloy steel. I. James H. Critchett. *Chem. Industries* **46**, 285–90(1940). E. H.

Solubility of nitrogen in steel. Lennart Eklund. *Jernkontorets Ann.* **123**, 545–55(1939).—The soly. of O-free N_2 in molten steel was detd. by passing it into the melt through a Pythagoras tube. The compn. of the steel was: 0.03–0.04% C, 0.07% Mn, 0.01% P, 0.014% S, with traces of Si. The crucible was alumina, and heated in a high-frequency furnace. Samples were taken by dipping steel tubes (0.15% C) into the melt and chilling, or by ladling. A stream of N_2 was maintained through the furnace during sampling to avoid contamination with air. Borings or turnings from the chilled sample were taken for analysis for C and N. Nitrides were detd. by dissolving in dil. HCl followed by distn. of NH_3 with NaOH. Insol. nitrides were filtered off and dissolved in concd. H_2SO_4 and Na pyrosulfate. The N content was 0.042% at 1550°; 0.043% at 1650°; and 0.044% at 1700°. At 1550° the effect of C on the soly. was studied. Up to 0.05% C, the N content was 0.042%, dropping to 0.034% with 1% C, 0.022% with 2% C and 0.011% with 4% C. Al has relatively slight influence on the N content, the increase being 0.002% for an increase of Al from 1% to 3%. The rate of satn. was found to be 100 min. at 1400°, 60 min. at 1550°, 50 min. at 1650° and 25 min. at 1700°. Temps. were measured by a Holborn-Kurlbaum pyrometer through a total reflecting prism. H. C. D.

X-ray diffraction study of grain boundary inclusions in steel. Raymond Morgan, Sylvia Steckler and E. B. Schwartz. *J. Franklin Inst.* **229**, 191–9(1940).—Samples were cold-worked, annealed, the surface was removed by filing, and the then-cleaned samples were dissolved in NH_4 persulfate. No α FeOOH (goethite) was found in the grain boundaries of either transformer steel or low-C steel. The x-rays showed that the impurities segregated at the grain boundaries occur principly in cryst. form and only to a small extent as amorphous material. 9 references. J. N. Lynn

The fatigue resistance of steels as affected by acid pickling. G. L. Kehl and C. M. Offenhauer. *Trans. Am. Soc. Metals* **28**, 238–54(1940).—A 0.54% plain C steel was used. Pickling under standard conditions (12 min. in 10% H_2SO_4 at 149°F.) reduced fatigue resistance 2%; increase of pickling time further decreased fatigue resistance most pronouncedly from times of 5 to 22 min., and to a const. level after 105 min. Di-*o*-tolythiourea and Acitrol-100 inhibitors minimized the formation of deleterious surface notches and prevented decrease in fatigue properties. After 22 min. the results were practically the same as those from an uninhibited bath. The fatigue life of the material is independent of the acid concns. investigated (5 to 20%), other conditions of time and temp. remaining const. Increase in temp. of the pickling bath between 131° and 167°F. resulted in a pronounced decrease in fatigue properties. Photomicrographs of av. surface conditions are included. W. A. Mudge

Some problems on quenched steels. I. Cracks of quenched steels. Kaizo Monma. *Science Repts. Tohoku Imp. Univ., First Ser.*, **28**, 128–34(1939).—Quenching cracks are due to shrinkage of a thin layer of martensite on the surface of the sample, obeying the reaction $\alpha \rightarrow \beta$ (martensite) accompanied by a vol. change. Tempering at 150° allows the entire specimen to transform to β martensite; this prevents cracking. **II. Temper cracks of quenched high-speed steel.** *Ibid.* 134–42.—After quenching high-speed steel from 1300° no cracks were observed. However, tempering between 500° and 650° only caused temper cracks. In this case, the temper cracks were due to tensional stresses in a decarburized zone by martensitization of the retained austenite of the inner portion. Freedom from decarburization prevents this type of crack. J. N. Lynn

Carbide heterogeneity of ball-bearing steel and means of eliminating it. V. P. Remin. *Metallurg* **14**, No. 4–5, 57–63(1939).—Carbide segregation in ingots of 52100 steel is caused by a heterogeneous melt and can be avoided by adding the ferro-Cr in the early part of the heat. Even rapidly cooled samples from heterogeneous melts had carbide segregation. Before rolling, steel should be soaked at 850–1100° to permit diffusion of carbides and avoid carbide stringers in the rolled product. H. W. Rathmann

Heat capacity of carbon steel. Ya. A. Turovskiĭ. *J. Tech. Phys.* (U. S. S. R.) **9**, 1613–25(1939).—From Gruneisen's equation (*C. A.* **7**, 722) of state an expression is deduced giving c_p as a function of density, thermal expansion, Young modulus, and shearing modulus. The c_p of a carbon steel (C 0.5%) calcd. from this expression rises from 0.14 at 500° to 0.43 at 720° and falls to 0.18 at 800°. For the calcn. unpublished values of Young modulus and modulus of shear between 600° and 1000° were used, e. g., at 900° 970,000 kg./sq. cm. for the first and 370,000 kg./sq. cm. for the second one. J. J. B.

Hardness characteristics of some medium-carbon S. A. E. steels. P. Klain and C. H. Lorig. *Trans. Am. Soc. Metals* **28**, 83–121(1940).—The hardening characteristics of 16 S. A. E. plain C and alloyed medium-C steels, as revealed by a definite testing procedure, were examd. on quenched and on quenched and tempered specimens ½ in., 1 in., 2 in. and 3 in. in diam. by 7 in. in length. Transverse hardnesses were detd. from duplicate specimens after suitable machining. The results are summarized in many tables and curves, the latter plotted to show changes in hardness for different tempering temps. at the surface, at half radius and at the center of the specimens of different diams., and to show the change in hardness across the section for each tempering temp. W. A. M.

The effect of hardness and of temperature on the strength, ductility and toughness of a heat-treated carbon steel. S. W. Lyon. *Trans. Am. Soc. Metals* **28**, 128–40

(1940).—Tension, impact-tension and impact-bending tests were made on unnotched specimens of a 0.73% C steel, heat-treated to produce a range of hardness of Rockwell C-22 to C-65, at temps. from plus 70° to minus 70°F. The steel lost strength quite markedly in the range of Rockwell C-47 to C-52. The toughness was not greatly affected. A useful curve is given to det. the energy correlation between full-size and fractional-width unnotched impact specimens. W. A. Mudge 1

The effect of speed of loading upon the ductility of structural steel. Gordon L. Jeppesen. *Bull. Assoc. State Eng. Soc.* **14**, 96–100, 102–4(Apr., 1939).—Tests were made of plates and of joints. Conclusions: (1) A brittle-appearing fracture in a member is not proof that the member has had no appreciable elongation before failure. (2) The ductility of structural steels tends to increase rather than decrease with an increase in speed of loading. (3) To the naked eye, the fracture under static and the high-speed loadings used in these tests is the same in appearance. (4) A wide thin plate is as strong as a narrow thick plate. (5) For specimens tested, a welded member is more effective in resisting energy loads than is a plate with a hole in it, of the same net area. W. H. Boynton 2 3

Hardenability variations in the alloy steels. Some investigations with the end-quench test. Gordon T. Williams. *Trans. Am. Soc. Metals* **28**, 157–81(1940).—S. A. E. Steels 1035, X-1020, 3140, 3150, 4150 and 4340, and 2 special alloy steels contg. C 0.63, Mn 0.66, Cr 0.58 and Ni 1.15%, and C 0.55, Mn 1.19 and Cr 0.57, resp., were studied. The Jominy-Boegehold end-quenched hardenability test is not crit. with respect to length or diam. of specimen, nor as to quenching-water temp., and gives excellent reproducibility of results. Steels closely similar in chem. analysis for principal elements may require widely different times at heat to develop max. hardenability below grain-growth temp. Homogeneous austenite before quenching is required for max. hardenability; degree of banding is a possible indication of the ease or difficulty with which this will be attained. Deoxidation with Al, V and Ti gives fine grain size coupled with intense hardenability. Curves give exptl. results. W. A. Mudge 4 5

An analysis of machinability data from cold-finished and heat-treated S. A. E. 1045 Steel. O. W. Boston and W. W. Gilbert. *Trans. Am. Soc. Metals* **28**, 186–205 (1940).—The results of a series of tests to det. the relation between mech. properties and microstructure to machinability for several logs of a 3-in.-diam S. A. E. 1045 steel show (1) if the cutting speed for a given tool life of the oil-quenched log = 100, then quenched and drawn at 600° = 111, quenched and drawn at 1000° = 124, cold-finished = 168 and annealed = 180; and (2) values of tool life in min., for a cutting speed of 130 ft. per min., are 0.3, 0.8, 20, 37 and 64, resp. Typical photomicrographs are given. W. A. Mudge 6

Choice of the quality of the steel and the heat treatment of heavy-duty springs. T. V. Sergievskaya. *Kachestvennaya Stal* **6**, No. 2, 29–33(1938); *Chem. Zentr.* **1938, II**, 3451.—Investigations are reported on 3 spring steels: (1) a Cr-Si steel contg. C 0.6, Cr 1.54 and Si 1.15%; (2) also a Cr-Si steel contg. C 0.47, Cr 1.66 and Si 1.15%; and (3) a Ni-Si steel contg. C 0.6, Si 1.37 and Ni 1.4%. The most satisfactory treatment for the first was hardening in oil at 830° and annealing in Pb at 400–420° with subsequent cooling in air. For the 2nd steel hardening at 925° and Pb annealing at 400–430° are recommended and for the 3rd steel hardening at 870° followed by annealing at 380–420°. After tempering, this last steel possesses a tensile strength of 130 kg./sq. mm. with a reduction of area of 40%. M. G. Moore 7 8 9

Transformation of residual austenite in alloy steels at temperatures below 0°. A. P. Gulyaev. *Metallurg* **14**, No. 3, 64–71(1939); cf. *C. A.* **33**, 7254⁸.—Specimens of steel contg. (1) C 0.74, W 18.2, Cr 4.01 and V 0.58%; (2) C 1.85 and Cr 10.38%; and (3) C 0.44, Cr 11.0 and Si 3.85% were quenched in oil from 900–1300° and immediately further cooled to −183°. Magnetic measurements showed that the austenite-martensite transformation occurred between definite temp. limits and that these limits were below 0° if the steel was quenched from 1200° or 1300°. If the steel was quenched from a lower temp. the transformation took place above 0°. The amt. of residual austenite was greater if the steel was quenched from a high temp. If the specimen was held at room temp. after quenching the austenite became stabilized and did not transform so readily nor completely on subsequent cooling below 0°. H. W. Rathmann 10

Effect of manganese concentration on the rate of combustion of carbon and on the quality of steel. L. Katsen and Ofenhaenden. *Metallurg* **13**, No. 9, 37–40(1938); *Chimie & industrie* **42**, 276.—Addn. of ferro-Mn during the fusion of steel is undesirable because it considerably reduces the rate of combustion of C and thereby affects the quality of the steel. The optimum Mn content of the steel is not always the same: if the Mn comes from reduction of the slag, the optimum is 0.35–0.45%; if it comes from the addn. of ferro-Mn it should not exceed 0.32%. A. Papineau-Couture 11

Steel with 1.5% chromium for permanent magnets. V. A. Erakhtin. *Kachestvennaya Stal* **6**, No. 2, 26–8 (1938); *Chem. Zentr.* **1938, II**, 3451.—Studies are reported on 2 steels contg. about 1% C and 1.5% Cr in order to det. the most satisfactory heat-treatment to give high permanent magnetic properties. The following twofold treatment is recommended: (a) hardening at 1050–1100° with a retention period of 5 min. and cooling in air and (b) hardening to martensite at 830–50° with a 10-min. retention period and cooling in oil. In special cases hardening to martensite can be done from temps. of 780–800° in warm or cold water (with the addn. of salt). Such a treatment assures a coercive force of ≥58 oersted and a remanence of ≥9000 gausses. M. G. Moore 12

Changes of the carbide phase in stainless steel with a high content of carbon, chromium and molybdenum during its thermal treatment. I. G. Oreliovich. *Metallurg* **1938**, No. 12, 61–7; *Khim. Referat. Zhur.* **2**, No. 5, 78 (1939).—The phase changes on hardening and annealing of stainless steels contg. C 0.67, Cr 16.2, Mo 2.06, Si 0.37, Mn 0.27, S 0.006, and P 0.004% were investigated. The basic crit. points and the temps. of hardening and annealing were investigated by dilatometric analysis, by study of the microstructures and by analysis of the carbides. The optimum temp. for hardening in oil was found to be 1050–75°; that for annealing, 750–800°. W. R. Henn 13

The effect of heat-treatment on the stress-strain diagram of chrome-nickel steel. Keiiti Ota. *J. Iron Steel Inst., Japan* **23**, 1198–1207(1937); *Chem. Zentr.* **1938, II**, 3450.—Studies are reported on the effect of various types of heat-treatment of Cr-Ni steel contg. C 0.3, Ni 3.3 and Cr 0.8% on the stress-strain diagrams, especially the yield point and the yield ratio (ratio of tensile strength to yield point). When annealing is done after quenching at a temp. of 40° above Ac_1, the carbides begin to agglomerate in crystallographic planes. For this reason the diagram changes, the yield point becomes lower and the yield ratio suddenly increases. When the annealing temp. is held in the neighborhood of Ac_1 the agglomerated carbides form a beautiful striated structure, which is designated as laminar sorbite. The yield point gradually falls while the yield ratio rises considerably. By reducing the velocity of cooling during the quenching process the yield point is likewise lowered while the yield ratio increases. Changing the velocity of cooling during annealing is without effect. By the use of a double quenching (the 2nd quenching following the 1st and preceding annealing) it is possible to obtain 2 completely different sets of properties in the steel depending on the temp. of the 2nd quenching. When the 2nd quenching is from 680–730° a laminar sorbite structure is obtained with a low yield point and a comparatively high yield ratio. When this temp. is 740–70° granular pearlite forms and the yield point is relatively high while the yield ratio is unusually low. M. G. Moore 14

Impact properties of some low-alloy nickel steels at

temperatures down to −200°F. T. N. Armstrong and A. P. Gagnebin. *Trans. Am. Soc. Metals* **28**, 1–19 (1940).—Keyhole-notch and vee-notch impact tests with exptl. cast steels contg. C 0.03–0.18, Ni 0–4.95 and Mo 0–0.45%, and with exptl. wrought steels contg. C 0.09–0.17, Ni 0–3.61 and Mo 0–0.31%, together with tests on specimens of com. steels, were made at temps. down to −200°F. Good impact values were obtained with (1) properly deoxidized, normalized and drawn cast steels contg. C max. 0.15 and Ni 3.50–4.00%, and with the same C, Ni 2.75 and Mo approx. 0.30%; (2) normalized and drawn wrought steels contg. C max. 0.17 and Ni min. 2.75%; (3) normalized and drawn wrought steels contg. low C and substantial quantities of Ni and Mo, that have been deoxidized with Al; (4) any of these wrought steels after liquid quenching and drawing; and, (5) higher-C, fine-grained Ni, Ni-Mo and other Ni alloy steels that have been quenched and drawn. Providing the soundness of welds can be assured by non-destructive methods, welds made with heavily coated, low-C, 2.50% Ni, 0.20% Mo steel electrodes will meet most impact-resistance requirements down to −150°F. and possess a better combination of tensile and low-temp. impact properties than many other steels. W. A. Mudge

Effect of carbon and molybdenum on the isothermal transformation of austenite. F. V. Vdovin and E. P Akimova. *Teoriya i Praktika Metallurgii* **1938**, No. 10, 53–9; *Khim. Referat. Zhur.* **2**, No. 5, 78–9(1939).—For detn. of the transformation of austenite the magnetometric method gave the same results as did the study of the microstructures of tempered alloys. In steels contg. 0.5–1.1% of C and 1.0–8% Mo the temp. region of the max. stability of austenite is lower than that of plain C steels. Increase of the content of Mo from 1.0 to 8.0% increases the stability of austenite only at temps. of tempering so high that all its components pass into the solid soln. Increase of the C content from 0.5 to 1.1% with a given content of Mo increases the stability of austenite in the same manner as in Mo-free steels. W. R. H.

New ways for the production of hard metals. R. Mitsche. *Berg- u. hüttenmann. Monatsh. montan. Hochschule Leoben* **87**, 185–6(1939).—The com. sintered hard metals have either Ti or W carbide as bases. The Ti-contg. carbides are especially suitable for steel, while those on a pure W basis are particularly well suited for working cast metals or others giving short chips. The heat cond. of sintered W carbide is improved by addn. of about 6% Co as binder, to 0.185 cal./sec./°C./cm., which is about 3 times as high as for the ordinary high-speed steels (0.061). A new process for producing Ta carbides consists in dissolving Ta and C in molten Al and heating the melt in a graphite crucible to about 2000°; after cooling, the solidified melt is treated with acids so that Al and the Al carbide also formed are dissolved and Ta carbide remains as golden-colored crystals. This Ta carbide differs considerably in its phys. properties (d. 14.85 and C content 6.22%, which corresponds exactly to TaC) from that obtained by carburization of Ta (d. 14.05 and C 5.75%). Tools made of this material with binders of W and Ni had a higher mech. strength and resistance to abrasion, heat cond. being about the same as that of the high-speed steels. $WTiC_2$ is made in a similar manner but in a Ni bath in which W, Ti and graphite are dissolved in a graphite crucible and heated to more than 2000°; the $WTiC_2$ formed is sepd. from the solidified melt by dissolving in aqua regia. Tools and cutters are made by grinding the crystals so formed with Co and W as binders, compressing the powders in hydraulic presses and sintering in a vacuum furnace. This so-called "Kenna" metal is made in 3 grades of 75.7–78 Rockwell hardness by changing the Co content; heat cond. for the hardest grade is 0.07, for the softest 0.12 cal/sec./°C./cm. M. Hartenheim

A survey of the more recently developed cutting materials. H. W. Pinder. *Heat Treating Forging* **25**, 387–90(1939); **26**, 73, 76–7(1940).—The properties, prepn., treatment, and application of cutting tools are considered under the following headings: high-speed steels, cast and cemented cutting alloys, and dispersion-hardening alloys. I. Hartmann

Influence of interfacial tension on the size of the solidification grain of metallic alloys. Paul Bastien. *Compt. rend.* **210**, 248–50(1940).—The grain size on solidification of pure Al (99.998%) is sharply reduced by small addns. of Mg, Fe or Si. This reduction is not explicable by any peritectic reaction (Nishimura, *et al.*, *C. A.* **31**, 1337[1]) or change in velocity of crystn. (Czochralski, *et al.*, *C. A.* **32**, 5743[2]). But the surface tension of such alloys, detd. in a bath of molten cryolite by the drop method (*C. A.* **30**, 3759[3]) shows that change in grain size is accompanied by decrease in surface tension; thus the values for the pure Al and the Al with addn. of Mg 2.07, Mg 6.98, Fe 0.1, Fe 0.5, Si 0.1 and Si 0.5%, are, resp. 168, 40, 36, 77, 70.5, 83 and 77 dynes/cm. C. A. Silberrad

The influence of continuous heating on the mechanical-technological properties of purest aluminum as dependent on cold-deformation. H. Wolf and H. Tuxhorn. *Aluminium* **22**, 14–20(1940).—When purest Al is used in industrial applications it is important that it is not subjected to continuous heating or that this is considered in the design, e. g., Al bus bars or cables exposed to sunshine, in chem. app., etc. Very extensive tests are described in which a material contg. Al 99.9968, Si 0.0020, Fe 0.0006 and Cu 0.0006% was heated at 20, 50, 70 and 100° in an oil bath and at 200, 300, 400 and 500° in air furnaces and in salt baths for 1, 10, 100 and 1000 hrs. and elastic limit, tensile strength, elongation, Brinnell hardness and Erichsen deepening were detd.; all the results in hard, semihard and soft state are given in tables and curves. For practical purposes it can be stated that when heated for a long time, purest Al loses its strength, independent of the degree of cold-deformation, at as low a temp. as 50° The deterioration in strength at 200° is so great that the soft annealed state is practically reached even in short-time heating. Up to 100°, the differences in mech. strength due to various degrees of cold-deformation remain unchanged. The greatest softness can be obtained by annealing the hard-rolled material at 200°. Continuous heating above 400° should be avoided as coarse-grain formation takes place in this range. In many practical applications it will, therefore, be correct to base the strength only on the figures of the soft-annealed state. M. Hartenheim

The behavior of the various structural constituents precipitated in pure aluminum in chipless deformation. H. Röhrig and J. Roch. *Aluminium* **22**, 21–4(1940).—If a plastic material is deformed, enclosed brittle foreign particles are gradually crushed; the splinters arrange themselves in lines and can have an extremely serious effect on the mech. properties of the material. The com. pure Al (99.5%) usually has enclosures of brittle Al_4FeSi_2 crystals; their behavior was followed step by step metallographically during the transformation from soft-annealed sheets of the Al to (preserving) cans. The hard crystals were clearly comminuted but the plastic base material fills the formed interstices completely. The eutectic Al-Al_4FeSi_2 pptd. in spherical form in the Al is practically not at all deformed or even crushed. In the production of cold-extruded cans, which must have a high corrosion resistance, it is more advantageous to use a material with less than 0.5% inclusion. M. Hartenheim

The recrystallization of aluminum. Ernst Kratz. *Aluminium-Arch.* **6**, 7–25(1937); *Chem. Zentr.* **1938**, II, 3452.—By means of measurements of hardness, x-ray investigations and microscopic studies, the influence of small amts. of the metals Mg, Si, Mn and Cu on the recrystn. temp. of very pure Al (99.9967% Al of the Compagnie de Produits Chimiques d'Alais, Froges et Camargues) was detd. The addn. of these metals up to the limits of soly. raised the recrystn. temp. A relation between the amt. of dissolved metal and the recrystn. temp. could be detected only with Mg. Pure Al with 90% deformation begins to recrystallize after heating 2 hrs. at 100°. At 150° the recrystn. is ended after 24 hrs.; at 220° after only 2 hrs. Al contg. 0.5% Mg (also 90% deformation) first begins to recrystallize at 200° and at

320° recrystn. is complete after 2 hrs. With increasing Mg content the temp. at which recrystn. begins rises; at 2% Mg, it is 240°. The addn. of up to 0.1% Si increases the temp. at which recrystn. begins to 210°. With the addn. of about the same amt. of Mn the recrystn. begins after heating 2 hrs. at 230° and at 350° is complete after 2 hrs. At a Cu content of 0.05–0.4% recrystn. begins after heating 2 hrs. at 180° and is complete after 7 hrs. at 300°. M. G. Moore

The solubility of iron in aluminum. Albert Roth. *Z. Metallkunde* **31**, 299–301(1940).—Elec.-cond. and tensile-strength measurements were carried out on alloys contg. 0.0019–0.310% Fe. The soly. of Fe in Al was detd. to be about 0.01% at 320° and 0.02% at 600°. The cond. of hard-drawn wires of Al contg. a small amt. of Fe and only traces of Si reaches a well-defined max. at 325° on annealing. This is ascribed to pptn. of Fe from the solid soln., the beginning of which is also marked by an increase in the tensile strength. E. A. Peretti

The production of aluminum cable covering. Walter Deisinger. *Z. Metallkunde* **31**, 305–10(1940).—Expts. performed in the Cable Works of the Siemen-Schuckert firm are described, and pictures of the app. used and products made are presented. The process used is similar to that used to cover cables with Pb. Working temps. for 99.5% Al metal have to be 4 times higher than those for Pb. Al having a purity of 99.99% can be handled satisfactorily at temps. 2.5 to 3 times higher than for Pb. The relationship of temp. and pressure was detd. for both Pb and Al. E. A. Peretti

Shrinkage of aluminum alloys at solidification. O. N. Podvoiskaya. *J. Tech. Phys.* (U. S. S. R.) **9**, 1626–42 (1939).—The vol. change Δv due to solidification of Al-Si alloys cannot be correctly detd. by measuring the apparent weight of a sample immersed in salt melt at temps. above and below the f. p. since the solidified metal contains bubbles and pores. Consequently the sp. gr. of liquid alloys near the f. p., the sp. gr. at 20° and the thermal expansion between 20° and a temp. approx. 50° below the f. p. were measured; for the measurement of expansion an optical dilatometer was used. From these values Δv was calcd.; it was 6.5% for Al, 6.7% for Al + Si, 1.8 and Fe 0.2%, 4.1% for Al + Si 10.6 and Fe 0.3, and 2.1% for Al + Si 16.8 and Fe 0.3%. Al has d_{20} 2.707, and Al + Si 15.1 and Fe 0.4% has d_{20} 2.633. The coeff. of expansion of Al between 20 and 600° is 29×10^{-6}. The porosity of Al ingots increases with its Si content. 34 references. J. J. Bikerman

Aluminum-magnesium alloys. Ernst Herrmann. *Aluminium-Arch.* **7**, 7–24(1937); *Chem. Zentr.* **1938, II**, 3453; cf. *C. A.* **32**, 1637[1], 4130[1], 6999[5]. —A review is given of the historical development of Al-Mg alloys contg. more than 5% Mg. The effects of various admixts. as well as of different heat-treatments are discussed with references to the literature. A list is given of German, Swiss, French, American, English and Italian patents with their dates of application and publication, priority, and brief reports of their contents. M. G. Moore

Development of texture in sheets of brass, aluminum and Dural at rolling. A. E. Bryukhanov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1754–62(1939); cf. *C. A.* **33**, 5175. The Young modulus E of a rolled sheet of brass (Zn 38%) has a max. normal to the direction of rolling and a min. in this direction or under an angle of 18–36° to it. Al and Dural usually have $E_{max.}$ normal to the direction of rolling and $E_{min.}$ at 36–54° to it. The *elastic anisotropy* $(E_{max.}-E_{min.})/E_{min.}$ of brass, Al and Dural is approx. in the ratio 21:6:5. These data and x-ray patterns indicate that after a short rolling of brass the face (135) is in the plane, and direction [21$\bar{1}$] in the direction of the rolling; after a strong rolling (110) is parallel, and [112] normal to this direction. In rolled Al (135) is in the plane, and [21$\bar{1}$] in the direction of rolling. J. J. Bikerman

Recovery and recrystallization of metals with cubic symmetry after cold-rolling. A. E. Bryukhanov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1745–53(1939); cf. preceding abstr.—Annealing at 225–250° increases the E of rolled brass sheet irrespective of direction, and annealing at 300–750° increases the E in, and strongly lowers it normally to, the direction of rolling. The elastic anisotropy has a min. at 300–400°. X-ray patterns show a recrystn. between 215 and 300°; the new texture is destroyed above 400°. The E of rolled Al at an angle of 36–54° rises with temp. of annealing; at the other angles it increases to 250° and then diminishes again. J. J. Bikerman

Properties of monel containing beryllium, silicon and cobalt. I. Ya. Berkovskiĭ and F. N. Stepanov. *Metallurg* **14**, No. 2, 86–91(1939).—Monel contg. 1% Be has better mech. properties than a Cu-Be alloy contg. 2.5% Be or a Ni-Be alloy contg. 2% Be. Si up to 2.26% improves the properties of monel contg. 1% Be by as much as 18%. Addn. of Co has no beneficial effect. Monel contg. over 0.87% Be is subject to pptn. hardening. H. W. Rathmann

Properties and aging of Y alloy. Hideo Nishimura. *Japan Nickel Rev.* **8**, 8–21(1940).—The Al-Cu-Mg, Al-Cu-Ni, Al-Mg-Ni and Al-Cu-Mg-Ni systems are discussed. The effects of various amts. of Ni, Mg and Si and of different soln. and aging treatments on the mech. properties of Y alloy are investigated. Dialometric changes were found at 80 and 280° in specimens quenched from 500°. Cast Y alloy has a tensile strength of 21.5 kg./sq. mm. at room temp., 21.2 at 200°, 18.4 at 300°, 8.2 at 400° and 2.0 at 500°. James W. Poynter

The effect of nitrogen on chromium-containing alloys. A. M. Samarin, M. L. Korolev and I. V. Paisov. *Metallurg* **1938**, No. 11, 80–3; *Khim. Referat. Zhur.* **2**, No. 5, 78(1939); cf. *C. A.* **33**, 1645[6]. —N increases the strength and lowers the malleability of high-Cr alloys. With an increase of N the structure becomes more fine-grained. The smaller the ferrite grains the greater the tensile strength, the limit of plastic flow and the notch-bar impact strength. W. R. Henn

Bronzes for resisting water pressure. Syuzô Yamato. *Imono.* **12**, 1–24(1940).—Studies were made on large bronze cylindrical castings for resisting water pressure. A zinc bronze contg. 0.5–1.0% Ni and 0.5% Pb is best; for a satisfactory casting a feed head or heads should be located on the cylindrical part and chill plates should only be used on the inner face of the cylinder. The pouring temperature is 1100–1150°. M. Ishida

Antifrictional properties of manganese bronze. N. N. Serafimov. *Metallurg* **13**, No. 1, 112–14(1938); *Chem. Zentr.* **1938, II**, 3451–2. —A bronze contg. Cu 54, Mn 2.6, Pb 1.10, Fe + Al 0.40%, and the rest Zn, which showed the structure of α/β brass, was found to possess antifrictional properties inferior to those of Cr-Ni steel. This was true of the bronze in the wrought or forged condition or when used as screw or worm gears. It can thus be used for a substitute for ordinary brass only when the economic advantage is particularly important. M. G. Moore

Analysis of the Gahlstorf gold ring, and its relation to other finds. Helmut Otto. *Jahresschr. Focke-Museum, Bremen* **1939**, 48–62; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 732.—Spectroscopic analysis of the Gahlstorf gold ring gives Au 75.49, Ag 19.52, Cu 4.86, Sn 0.05, with traces (i. e., less than 0.01%) of Pb, Si, As and Zn, and no Bi, Sb, Fe, Pt, Ti or Ni; d. 15.3. This compn. resembles that of 2 ancient rings found in Ireland, but differs from that of several samples of native Au. C. A. Silberrad

Transitions of the solid solution in iron-chromium alloys. V. N. Svechnikov. *Metallurg* **13**, No. 4, 45–9 (1938); *Chem. Zentr.* **1938, II**, 3372; cf. *C. A.* **31**, 4942[7].—A crit. review of the $\alpha \rightarrow \gamma$ transition in solid Fe-Cr solns. M. G. Moore

Some observations on the recrystallization of an iron-nickel alloy. Geo. Sachs and J. Spretnak. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1143**, 7 pp.(1940).—**The rolling and annealing structures of a relatively pure Fe-Ni (36%) alloy were investigated with x-rays. Pole**

figures for the rolling structure were similar to those of other face-centered cubic crystd. metals, owing to superimposition of (111) and (112) structures. A certain amt. of cubic structure was detected. The pole figures of the annealed and the annealed plus 10% reduced samples showed mainly cubic structure, with some remaining rolling structure. Alden H. Emery

The solubility of lead in tin. A. Stockburn. *J. inst. Metals* **66**, No. 861, 33-8(1940).—The m. ps. of Pb-Sn alloys contg. 1.0, 1.5 and 2.0% Pb were detd. by microscopic examn. and by an elec. resistance method. The solidus of the 1.0% Pb alloy is 208-212°, of the 1.5% Pb alloy 193-198°, and of the 2.0% Pb alloy 183-186°. James W. Poynter

Fusion of magnesium alloys in hydrogen, K. V. Peredel'skiĭ. *Tsvetnye Metal.* **1938**, No. 8, 102-5; *Khim. Referat. Zhur.* **2**, No. 5, 81 2(1939).—Ordinary electron metal, contg. 8-10% of Al, was melted in a crucible heated in an elec. resistance furnace in an atm. of pure dry H. The alloy was mixed and held for 5-10 min. at 700-10°, then cast. The operation must be completed in 20-40 min. to insure good quality in the cast alloy. A slower procedure produces a porous metal with imperfections and with considerably poorer mech. properties. The alloy properly fused under H has a breaking strength of 17.4 kg./sq. mm. with an elongation of 2.7%; its microstructure does not differ from that of electron metal obtained by ordinary fusion. W. R. Henn

Magnesium alloys for photoengraving. Robert T. Wood. *Metals & Alloys* **11**, 33-41(1940).—The Mg alloy found most suitable for photoengraving is one contg. 3% Al and 1% Zn. The prepn. of the plate for etching, the etching technique, the repair of damaged plates, and their life are discussed. The most suitable etching soln. for Mg consists of 1 part 40°Bé. HNO_3 to 15 or 20 parts water. The following advantages are listed for Mg etching plates: (1) Mg plates can be processed by all 3 commonly employed light-sensitive tops; (2) they are suitable for line cuts, coarse-screen or fine-screen work and thus capable of replacing both Cu and Zn, allowing the plant to standardize on one plate material and one processing method; (3) the plates can be processed more rapidly than either Cu or Zn plates; (4) they allow longer runs when used for direct printing; (5) the plates weigh less than one-quarter as much as Zn plates and less than one-fifth as much as Cu plates. I. Hartmann

Compressed alloys of magnesium containing intermetallic compounds. K. V. Peredel'skiĭ. *Aviapromyshlennost* **1939**, No. 1, 32-4; *Khim. Referat. Zhur.* **2**, No. 5, 82(1939); cf. *C. A.* **34**, 699[9], 700[1].—Alloys of Mg with a content of $ZnSb_2$ 5, Pb_4Sn_3 2, $MgZn$ 10, Al_3Mg_4 15 and Cu_6Sn 10% were subjected to compression after fusion and casting into molds to produce a rod 10 mm. in diam. The compressed samples of the alloys were subjected to thermal treatment at 380° for 30 hrs., quenched in water and aged at 170° for 24 hrs. The investigation of the mech. properties of the alloys after the thermal treatment showed (as compared with the results obtained before the thermal treatment) that the breaking strength increased in the Mg alloys with 10% of MgZn, but decreased slightly in the remaining alloys. The elongation of the alloys increased, except that of the alloys with 2% of $PbSn_3$. W. R. Henn

Some properties of calcium-bearing magnesium alloys. Walter Bulian. *Z. Metallkunde* **31**, 302-4(1940).—The elastic limit, yield point and tensile strength of extruded rods of Magnewin (2% Mn, 0.3% Al, rest Mg) are increased considerably by the addn. of 0.1-0.2% Ca. Ca also improves the elongation of rolled metal without deleteriously affecting the resistance to corrosion. Ca has little effect on the properties of 3 and 6% Al-Mg alloys. E. A. Peretti

Melting practice and furnaces for zinc alloys. H. Barbier. *Metallwirtschaft* **18**, 1020-3(1939).—Two types of Zn alloys are most widely used: I contg. Al 3.8-4.3, Cu 0.9-1.3, Mg 0.02-0.06% and II contg. Cu 3-5, Al 0.15-0.25%. I should not be heated beyond 500° or II beyond 600°; the casting temp. for I is 450-480° and for II 550-580°. It is important to stay within these temp. ranges. In general, crucible furnaces are to be preferred. Gas- and oil-fired furnaces are most popular. The temp. can be controlled well and held const.; this is important especially when small castings are to be produced and a ladle is used. The burner tip is flat and the flame strikes the crucible tangentially so that local overheating is avoided. Another type uses a burner which strikes the foot of the crucible. Furnace design for oil and gas heat is alike. In elec.-resistance furnaces care must be taken that the alloy does not come in contact with the windings. The heating-up time is relatively long. Otherwise this type is very well suited as far as furnace atm. and temp. control are concerned. Induction furnaces are used only for continuous operation. For large charges the furnaces should be pivotable. It is advantageous to withdraw the crucible from the furnace. For I, graphite or iron crucibles can be used. II requires graphite crucibles. Waste and turnings should not be used. Virgin metal is to be preferred and up to 50% waste from risers, lugs, etc., can be added. R. P. S.

Fine zinc-base bearing metals. E. Schmid and R. Weber. *Metallwirtschaft* **18**, 1005-10(1939).—Alloys with 4 and 10% Al, 0.5 and 1% Cu and 0.03% Mg for compensation of any traces of Pb and Cd were compared with ordinary bearing alloys. In static and fatigue strength the Zn alloys are superior and also the hardness is surpassed only by the Sn-bronzes. The elongation is low, however. The heat cond. of the Zn alloys exceeds that of the others tested. In order to test the running properties the bearing shells were chill-cast and then mounted in steel backings. The bearing surfaces were diamond finished, the shanks were unhardened, the surface ground. Temp. curves during the break-in period at max. speed and appearance of the surfaces afterward show that the Zn alloys act essentially like the red brass, some were similar to Sn bronze and in 2 instances the break-in characteristics were equiv. to those of babbit metal. Also in the service test with varying speed and loads the Zn alloys proved equiv. to the orthodox metals. A few emergency tests without lubrication gave an indication of superior characteristics of the Zn-base bearing alloys. There is not sufficient evidence to decide which of the tested Zn alloys is to be preferred. Tests with centrifugally cast shells are considered essential. Richard P. Seelig

Production and subsequent working of zinc-alloy tubing. H. Kästner. *Metallwirtschaft* **18**, 1010-15.—Cu-bearing Zn alloys are extruded between 200° and 240°; these low temps. require high pressures and high speed. Alloys with 4% Al and minor Cu contents are extruded between 240° and 270° and with 10% Al between 270° and 300°. The extrusion dies must have tapered entrance. The extrusion speed is considerably lower than for brass. The extrusion pressure is higher than for brass, about the same as for high-strength Al-Cu-Mg alloys. The initial pressure drops on continued extrusion. Since the mech. and technological properties of most Zn alloys are impaired by cold-working the tubing should be hot-extruded as close to the desired dimensions as possible. Cold-drawing is used mostly for finishing and the reciprocating rolling process is gaining in importance. In the latter process a much higher reduction per pass is possible; the deformation is more uniform. The effect of intermediate annealing depends largely on the alloy used; as a rule annealing does not improve drawing properties. The change of properties with deformation was studied by comparing the tensile properties of two Zn alloys with those of an Al alloy and a brass after each rolling or drawing pass, resp. In all cases a stress velocity of 15 mm./min. was maintained; for Zn alloys a wide variation of readings was found with changing rate of loading in the tensile test. The Zn alloys act very differently from the other materials. The tensile strength rises first, without any drop in elongation. With increased reduction in cross section by drawing, the tensile strength drops sharply and the elongation rises. The hardness of 63% brass increases uniformly with the degree of deformation. The Zn-Al (4%) alloy has practically const. hardness after it

is increased up to a certain value. The Brinell nos. for the Zn-Cu (4%) alloy rise first, pass a broad max. and drop later to the original value of the extruded tubing. A comparison of the same degree of reduction, one produced by rolling, the other by drawing of the Zn-Cu alloy, showed a slight increase in strength and marked increase in elongation by rolling, and a decrease in strength and unchanged elongation by drawing. The bending of Zn-alloy tubing can be done hot or cold; the tools and tubing are preferably preheated. In order to avoid cross-sectional changes during bending the tubing should be filled with fine absolutely dry sand. The use of low-melting materials such as Wood's metal or Pb is not recommended. All other working operations (spinning, twisting, etc.) are to be performed on hot material. 1 2

Richard P. Seelig

The practical value of the copper sulfate test in galvanizing. Carlos F. Hickethier. *Mecanica Metalurgica* No. 65, 5 pp.(1938); *Chem. Zentr.* 1938, II, 3455.—The $CuSO_4$ immersion test was found to be only poorly suited for the abs. estn. of the thickness of a Zn coating but it does offer a means of judging the uniformity of the coating. 3

M. G. Moore

The hot-dip zinc coatings of welded gas pipes. Yasuzo Ogino. *Tetsu-to-Hagane* 26, 20–42(1940).—O. utilized, in his expts., a zinc-bath, 7000 × 760 × 1200 mm. deep, so that his results would be easily comparable with the results obtained from the daily factory work. For the same reason ¾" butt-welded pipe was used. M. Ishida 4

Pinhole corrosion in galvanized watering tanks. W. M. Pierce and G. C. Bartells. *Metals & Alloys* 11, 42–4 (1940).—High Sn content (approx. 0.4% or more) is the primary factor leading to pinhole corrosion of galvanized steel sheets under conditions of total water immersion. The following explanation is offered for this: Sn is present in a Sn-Zn alloy as free Sn in the grain boundaries, and as such it is known that it electrolytically accelerates the corrosion of both Zn and iron; it may be expected to behave similarly with respect to the alloy layers whose potentials are between those of Zn and iron. 5

I. Hartmann

The change of the zinc potential toward a nobler value in hot tap water. G. Schikorr. *Metallwirtschaft* 18, 1036–8 (1939); cf. *C. A.* 33, 7671⁶.—In hot tap water Zn can become nobler than Fe. This is explained by the fact that above 60° the corrosion products of Zn are deposited in a very dense and adherent form. The app. used for measuring the potentials is described. The failure of pipes in certain spots is attributed not to material flaws but to a combination of unfavorable conditions; e. g., it is assumed that when air bubbles are present the Zn coating may be destroyed before a protective film can be formed and that later, when the air is swept away, corrosion can proceed unhampered. 6 7

Richard P. Seelig

Preventing rust and corrosion. Wilhelm Lambrecht. *Farben-Chem.* 10, 304–8(1939).—This is a review of methods known in the 19th century for preventing rusting of Fe, e. g., by formation of a protective coating of oxide or basic salt, by coating with another metal, such as Zn or Sn, by application of paints made from boiled linseed oil, asphalt, etc. 8

J. W. Perry

Researches on the stress-corrosion of aluminum-magnesium forging alloys. Annaliese Mühlenbruch and Hugo J. Seemann. *Z. Metallkunde* 31, 293–9(1940).—Alloys of Al with 8–9% of Mg, 0.3% Mn, 0.3% Fe and 0.1–0.2% Si were tested by the salt spray and alternate-immersion tests after various heat and mech. treatments. All the alloys were less resistant to corrosion in the aged state than in the cold-rolled, homogenized and slightly heterogenized states. Alloys heterogenized by slow cooling from the homogeneous state behaved somewhat better than did those quenched from the homogeneous range and heterogenized by reheating just below the solid-soln. line. Aging for 1 day at 100° gave more resistant metal than did aging at 75° for 14 days. Alloys made from Fe- and Si-free Al were less resistant than those made from com. metal. The addn. of 1% Zn to the alloys had no beneficial effect in any of the states tested. No relation could be established between grain size and the tendency to stress-corrosion. E. A. Peretti 9

Stress-corrosion cracking of the austenitic chromium-nickel steels and its industrial implications. James C. Hodge and John L. Miller. *Trans. Am. Soc. Metals* 28, 25–67(1940).—Service failures and exptl. results indicate that the austenitic Cr-Ni steels are susceptible to stress-corrosion cracking which may occur independently of its condition with respect to susceptibility to intergranular corrosion. Intercryst. corrosion favors stress corrosion cracking which is intercryst. or transcryst. dependent upon the corrosive medium, the stress magnitude and the degree of susceptibility. Aq. solns. of C_2H_5Cl, $FeCl_3$ and of $HgCl_2$ gave accelerated results. The tendency to stress-corrosion cracking increases with increasing stresses such as result from cold bending, welding or rapid cooling from elevated temps., and also by the use of composite structures such as a welded attachment between austenitic and ferritic steels having different thermal expansions. Removal of fabricating stress by thermal treatments utilizing slow cooling, which require the use of stabilized alloys contg. Cb or Ti to avoid intergranular corrosion, will eliminate stress-corrosion cracking. The mechanism of stress-corrosion failure is believed to be similar to that of corrosion-fatigue cracking. Excellent photomicrographs are given.

W. A. Mudge

Factors influencing external corrosion of tin containers. K. G. Dykstra. *Canner* 90, No. 12, Pt. 2, 68–71(1940) – General.

C. R. Fellers

Control of external corrosion of cans. C. L. Smith. *Canner* 90, No. 12, Pt. 2, 65–8(1940).—Conditions responsible for surface corrosion and discoloration are discussed. Some of these factors are sweating, corrosive cooling waters, Fe retort crates, hygroscopic residual salts, and poor cleaning.

C. R. Fellers

Electrolytic corrosion of metal objects in the soil using constant direct-current potential in Zurich and Neuhausen. H. Bourquin. *Schweiz. Ver. Gas- u. Wasserfach., Monats-Bull.* 19, 262–6(in French, 266–70)(1939).—In a set of expts. on soil corrosion at Neuhausen 200 × 50 × 2 mm. plates provided with elec. connection of the same metal were buried in a wooden box of 160 × 60 × 25 cm. filled with soil. The sidewalls of this box were provided with C electrodes. The boxes were set in the ground. In one box the metals were cathodes, in another one anodes, a const. voltage of 10 v. being applied to all. Fifteen metals were tested: bare steel, steel with Al bronze coating, Pb, Pb with asphalt coating, Cu, 99.99% Al, pickled 99.7% Al, pickled 99.7% Al treated by MBV process, 99.7% Al oxidized in H_2SO_4, 99.7% Al oxidized in CrO_3, Anticorodal Ho, pickled soft Al, pickled Peraluman 7, pickled Peraluman 2, pickled and cast Anticorodal of 2.5% Si. The expts. were conducted for 1 yr. and the test pieces weighed. The Fe anodes show more wt. loss than calcd., Pb anode losses are between those calcd. for bi- and quadrivalent Pb, Cu anode losses between those calcd. for uni- and bivalent Cu. The Al anodes all showed higher loss than calcd. Fe, Pb or Cu cathodes showed very little loss (a few %), Al or Al alloy cathodes showed appreciable loss, almost double the theoretical figure. Hence const. potential does not protect the light metal. Similar tests were conducted at Zurich using pipes made of the different materials and amp. hr. *vs.* time curves are given, a 6.3-v. potential used. Details of these expts. are given. The sp. resistance of the soil medium used was 20,000 Ohm. cm. With cathodic Al an addnl. resistance due to oxide crust is found. Conclusions: The basic difference between Fe, Pb, Cu on the one hand and Al alloys on the other is that the former are corroded only anodically, the latter both ways. Wt. losses for heavy-metal anodes as well as light-metal ones can roughly be calcd. by Faraday's law, light-metal cathodes suffer higher losses owing to a secondary reaction caused by alky. of the medium near the cathode. The use of Al or its alloys in the soil such as for cable covering is not advisable. It is too sensitive to stray currents. 10 11

B. J. C. van der Hoeven

Corrosion resistance of monel to beer. H. Siegfried. *Schweiz. Brau. Rundschau* 50, 197–98(1939).—Small

polished plates of monel immersed in fermenting wort lost a total of 37.2 mg. as compared to 50.3 mg. for unpolished plates after a total fermentation time of 129 days; in each case the beer stone was removed after each fermentation. When the stone was left, early fermentations gave a loss in wt., followed by a gain in wt. for later fermentations. After 94 days of fermentation only 6.3 and 7.1 mg. of Ni from the unpolished and polished plates, resp., passed into the beer; the difference must have passed into the yeast. Monel piping indicated negligible corrosion in the presence of flowing beer. Louis Laufer

Change of the composition of the electrode coating OMM-1. G. I. Bukreev and A. L. Polyakov. *Avtogennoe Delo* 8, No. 4, 20–2(1937); *Chem. Zentr.* **1938**, I, 4231.—In the welding of a steel contg. C 0.11, Si 0.11 and Mn 0.44% the use of a 4-mm.-thick electrode contg. C 0.24, Si traces and Mn 0.49% having a coating made up of Mn ore (26% Mn), 30, quartz 8.4, Fe oxide 4.4 and lamp-black 3 parts by wt. gave the most satisfactory results as regards strength of the weld seam. M. G. Moore

Theoretical principles involved in the production of electrode coatings in the welding of carbon steels. A. A. Erokhin. *Avtogennoe Delo* 8, No. 9, 30–4(1937); *Chem. Zentr.* **1938**, I, 4231; cf. *C. A.* **31**, 4255[1].—A brief review of the theoretical principles of slag formation in the welding of steel with the use of coated electrodes. M. G. Moore

Is the removal of forge scale from sheet iron for roll welding with a high-frequency arc expedient? V. A. Lapidus. *Avtogennoe Delo* 8, No. 8, 29–31(1937); *Chem. Zentr.* **1938**, I, 4230.—It is unwise to remove forge scale before welding for the following reasons: Removal of a forge scale layer 0.01–0.1 mm. in thickness from sheet iron 0.3–2 mm. thick before welding with a high-frequency arc is unprofitable. There is an unavoidable lack of uniformity in the thickness of the forge scale layer, and the strength of the sheet iron varies with the thickness of this layer. Cleaning the scale from the sheet metal is a slow process and impairs the quality of the material, especially in the case of thin sheets. M. G. Moore

Metallurgical processes in arc welding. I. D. Davydenko. *Avtogennoe Delo* 8, No. 3, 11–17; No. 4, 11–16 (1937); *Chem. Zentr.* **1938**, I, 4230.—Changes in the chem. compn. of the steel during arc welding and the effect of such changes on the mech. properties of the weld were studied. About 88% of the C content and about 50% of the Mn burn out, while the N content is greatly increased. Oxygen is present in the weld seam in the form of slag inclusions of various oxides, in the form of a solid soln. of Fe with FeO, and in the form of Fe droplets which are covered with a thin oxide coating. During welding, the oxidation of the fused steel is caused by direct contact with atm. O, by atm. O above the slag, by O in constituents of the electrode coatings, and the O of the slag oxides. These various oxidation processes are individually discussed. Other matters considered are the compn. of the weld slag and its importance in the area of the weld as well as deoxidation of the welded area under an acid or basic slag with Mn, Si, Al, Ni, Mo, Ca boride and ferrotitanium as deoxidizing agents. M. G. Moore

The nature of the spatter in arc welding. V. D. Taran. *Avtogennoe Delo* 8, No. 9, 17–19(1937); *Chem. Zentr.* **1938**, I, 4230–1.—The fine structure of the material spattered in the welding of hypereutectoid steel with electrodes of high C content shows cementite needles in an austenite field. The spatter produced in the welding of hypereutectoid steel with low-C (0.17%) electrodes shows the same structure as is obtained in the welding of hypoeutectoid steel (0.21% C) with electrodes of the same compn. From this it is concluded that the spatter is produced essentially from the material of the electrodes. M. G. Moore

The production of high-quality welds by automatic arc welding. P. P. Bustedt and V. I. Dyatlov. *Avtogennoe Delo* 8, No. 5–6, 3–8(1937); *Chem. Zentr.* **1938**, I, 4231.—Welding tests using thickly coated electrodes and an automatic welding device are reported. The electrode coating consisted of ilmenite 25.6, pyrolusite 12.8, fluorspar 25.6, ferromanganese 6.8, rye meal 17.2 and water glass 12%. The current used was 250–330 amp. M. G. Moore

Welding of heat-resistant austenite steels. K. G. Nikolaev. *Avtogennoe Delo* 8, No. 4, 37–9(1937); *Chem. Zentr.* **1938**, I, 4231.—Satisfactory arc welding of 2 such steels is reported. One steel contained C 0.26–0.42, Si 1.9–9.2, Cr 17–21, Ni 24–7, Mn 0.4–0.6% and the other C 0.15–0.22, Si 0.6–1.25, Cr 23–7, Ni 11–13 and Mn 0.33–0.5 %. The compn. of the electrodes used was C 0.15–0.6, Si 0.4–0.6, Mn 0.5–0.6, Ni 8–9, Cr 18–19 and Ti 0.5%. The electrode coatings were made up of a mixt. the dry portion of which consisted of fluorspar 48, marble 26, kaolin 6, ferrotitanium (12%) 12, ferrosilicon 3, and ferromanganese 5% and the liquid portion of water glass 75 and KOH (60% soln.) 25%. The electrodes were 4 mm. thick and the welding current 120–40 amps. The welded specimens possessed a tensile strength of 61–72 kg./sq. mm. with an elongation of 23–35% and a bending angle of 160–80°. M. G. Moore

The welding of stainless EJa-IT steel. I. L. Tukatsinskiĭ. *Avtogennoe Delo* 8, No. 8, 27–8(1937); *Chem. Zentr.* **1938**, I, 4231.—It is recommended that austenite stainless Cr-Ni steel (18% Cr, 8–9% Ni, and 0.4–0.6% Ti) be welded with the use of an electrode coating made up of 50 parts by wt. of marble, 50 parts fluorspar, and 15 parts ferromanganese to which has been added 78 cc. water glass and 70 cc. water per 500 g. of dry material. Data are given regarding the carrying out of the welding. M. G. Moore

Welding of high-manganese Hatfield steels. V. A. Batmanov, P. V. Sklyuev and S. G. Eiche. *Avtogennoe Delo* 8, No. 4, 17–19(1937); *Chem. Zentr.* **1938**, I, 4231.—The welding of hard Mn steel contg. C 0.9–1.3, Si 0.2–0.35, Mn 11.5–14.5 and Ni up to 0.25% is reported. After preliminary quenching in water from 1050–1100°, such steel can be satisfactorily welded with the use of the oxy-acetylene flame or with the arc if low-C electrodes contg. Mn 11–14 and Ni 3.5–4.5% are used. M. G. Moore

Electric welding of cast iron by the bath process. V. A. Lapidus. *Avtgennoe Delo* 8, No. 516, 28–30(1937); *Chem. Zentr.* **1938**, I, 4375.—Defective cast iron pieces can be repaired by elec. welding by the bath method of Slavyanov. The defective portion is first removed as far as possible by mech. means in such a manner that the depression remaining has smooth perpendicular side walls. Suitable forms are arranged to give the desired shape to the portion being rebuilt. The cast-iron specimen is then carefully heated and welded electrically with the use of a cast-iron electrode contg. C 4, Si 3.5, Mn 0.8, S up to 0.1, and P 0.5%, after which the specimen is carefully cooled. M. G. Moore

Welding of pure lead by pressure at various temperatures. Bruno Meyer and Heinrich Hanemann. *Z. Metallkunde* **30**, 422–4(1938).—Two pieces of Pb cannot be welded together by pressure in the air at any temp. below the m. p. Clean surfaces can be welded by pressure in absence of air, e.g., in the cable sheath extrusion press. It is therefore concluded that an oxide film forms immediately on exposing clean Pb surfaces to the air. B. C. P. A.

Solders for zinc alloys. G. Wassermann. *Metallwirtschaft*, **18**, 1018–20(1939).—By using a soldering fluid contg. Pb and small amts. of Sn a solder with very little Sn can be used. The relatively high m. p. of Pb is a disadvantage; flame-soldering is recommended. The method is not applicable to Al-contg. Zn alloys. This can be achieved by adding Zn to the solder in amts. of 1/4 to 1/2 of the Pb content. A small percentage of Bi lowers the m. p. and improves the bond. The joint should be absolutely clean and preferably coated with a little solder before joining the pieces. For Al-contg. alloys 40% NaOH soln. is used as soldering fluid. For all other alloys HCl can be used. The best and most universal solders for Zn alloys have Cd as their main constituent and some Zn and Pb. Pb can be substituted partly or completely by Sn. The same soldering fluids are used. Richard P. Seelig

Concentrating ores. Anderson W. Ralston, Wm. O. Pool and James Harwood (to Armour and Co.). U. S. 2,185,968, Jan. 2. Froth-flotation sepn. is effected in the presence of a mixt. of satd. and unsatd. aliphatic amines having 3–10 C atoms and satd. and unsatd. aliphatic straight-chain hydrocarbons.

Flotation of gold and other minerals. B. V. Nevskiĭ. Russ. 56,085, Nov. 30, 1939. Au is recovered and the flotation power of the froth is increased by adding to the pulp disintegrated wood chips after treatment with such reagents as tar, or heavy crude-oil bottoms, which moisten the gold or other minerals to be extd. but which do not moisten gang.

Flotation oils. L. M. Pesin, R. L. Globus, T. V. Sheremet'eva, T. L. Fabrikant and V. I. Lyubomilov. Russ. 52,225, Nov. 30, 1937. By-products of the manuf. of camphor from pinene are treated with HCl, the hydrochloride is heated with aq. alkali and the oil obtained is sepd. by rectification.

Depression of carbonaceous material in ore flotation. Robert B. Booth (to American Cyanamid Co.). Brit. 508,929, July 7, 1939. See U. S. 2,145,206 (*C. A.* **33**, 3319[8]).

Chlorinating chromium ores. Irving E. Muskat and Norman Howard (to Pittsburgh Plate Glass Co.). U. S. 2,185,218, Jan. 2. A Cr ore is chlorinated at a temp. (suitably about 850°) sufficient to volatilize Fe chloride, in the presence of sufficient gaseous O simultaneously to minimize the tendency of the ore toward sintering within the furnace. App. is described.

Chlorinating ores containing iron and titanium. Irving E. Muskat and Robert H. Taylor (to Pittsburgh Plate Glass Co.). U. S. 2,184,887, Dec. 26. A material such as ilmenite ore contg. Ti 20–50 and Fe 10–50% is treated by a continuous process with 15–35% of C and with Cl at such a rate that sufficient heat is evolved from the reaction to maintain the temp. at 600° or higher within at least a portion of the reaction zone, so that chlorides of Fe and Ti are formed and volatilized. App. is described.

Removing iron from titanium ores. Irving E. Muskat and Robert H. Taylor (to Pittsburgh Plate Glass Co.). U. S. 2,184,884, Dec. 26. A mixt. of C and a Ti ore contg. Fe is subjected to the action of controlled amts. of Cl and O at a temp. above 500° to effect formation and volatilization of Fe chloride. U. S. 2,184,885 relates to a generally similar process, except that O need not be used.

Roasting zinc concentrates. A. N. Vol'skiĭ and R. A. Agracheva. Russ. 52,217, Nov. 30, 1937. The formation of ferrite is inhibited in roasting zinc concentrates at low temps. by the addn. of sulfate-forming substances.

Apparatus suitable for melting metals such as lead for extrusion. Daniel V. McParlin (to Okonite-Callender Cable Co.). U. S. 2,185,376, Jan. 2. See Brit. 500,391 (*C. A.* **33**, 5352[3]).

Apparatus for producing filaments from materials such as molten lead. Adolph F. Krauss (to Richardson Co.). U. S. 2,185,442, Jan. 2. Various details of manuf. and operation.

Batch process for producing iron or steel. Fritz Eulenstein and Adolf Krus (to Sachtleben A.-G. für Bergbau und Chemische Industrie). U. S. 2,185,911, Jan. 2. A batch process for the production of iron in a rotary drum furnace comprises charging the furnace to its normal vol. capacity with a mixt. comprising more than a normal batch of ore, at least part of the reducing carbon required for the treatment of the ore, and less lime than is required for the treatment of the ore, heating the mixt. by direct flame, after the charged mixt. has contracted in vol. introducing sufficient lime to complete the treatment of the ore and agitating the contents of the furnace by rotary

movement of the furnace about a substantially horizontal axis.

Horizontal furnace for the continuous annealing of metal sheets, wire or the like. Emil Vits. U. S. 2,185,655, Jan. 2. Various structural, mech. and operative details.

Apparatus (with thermostatic control) heated by gas combustion and suitable for annealing metal plates, etc. John E. MacConville, Neel I. Cockley and James L. Whitten (to Brown Instrument Co.). U. S. 2,184,975, Dec. 26. Various structural, elec. and operative details.

Heat-treatment of magnesium-base alloys such as those for casting and heat treatment. Robert T. Wood (to Magnesium Development Corp.). U. S. 2,185,452, Jan. 2. A method of producing, in a casting of a Mg-base alloy contg. Mg together with Al 1–12, Zn 0.3–5, Mn 0.05–0.3 and Ca 0.03–0.3%, properties commensurate with those obtained by a 2-step soln. heat-treatment, involves subjecting the casting to a single step soln. heat-treatment at a temp. of about 380–415° for 5–30 hrs. and then rapidly cooling to below 205°. U. S. 2,185,453 relates to a similar heat-treatment of alloys of generally like compn. except that they do not contain Mn.

Deseaming blooms, bars, etc., of nickel and its alloys. Herman M. Brown (to International Nickel Co.). U. S. 2,185,496, Jan. 2. A process of deseaming blooms, billets, sheet bars and the like made of Ni or a Ni alloy involves striking an arc between the bloom, billet, sheet bar, etc., contg. a surface defect, and an electrode; moving the electrode along a surface defect to be removed while contolling the current in excess of about 300 amp. to cause metal about the defect to become molten and to be automatically removed as a result of elec. forces generated in the molten metal incident to the passage of current therethrough, thereby producing a groove adjacent to the surface defect in the bloom, billet, sheet bar, etc., and correlating the speed of the electrode along the defect with the current and the depth of the defect to produce a groove in the metal having a depth at least equal to the depth of the defect to be removed whereby a grooved bloom, billet, sheet bar, etc., free from surface defects is obtained which, when worked, provides an acceptable product having a surface free from seams, splits, cracks and other surface defects.

Multi-ply metal foil. Gustav Ruoff (to Calif. Fruit Growers Exchange). U. S. 2,185,649, Jan. 2. A material suitable for use with food products, etc., comprises 2 metal foils intimately united by an intervening layer of pectin.

Aluminum production and refining. Charles B. Willmore (to Aluminum Co. of America). U. S. 2,184,705, Dec. 26. A mixt. is formed contg. Al and a halide such as Na_3AlF_6 or MgF_2 and the mixt. is heated in an atm. "effectively inert" to Al, such as H, to vaporize the Al and the halide, resulting vapors are condensed, and the Al is sepd. from the condensate.

Prevention of porosity in aluminum castings. John H. Alden, Philip T. Stroup and Pasqual M. Budge (to Aluminum Co. of America). Can. 387,067, Feb. 27, 1940. Al or its alloys are melted, transferred to a holding chamber, a current of air contg. moisture not above 0.5 grain/cu. ft. is passed through the chamber, the alloy is degassed by bubbling Cl through it while it is protected by the air current, the vol. of current is decreased and the alloy heated to the desired pouring temp.

Magnesium. Hirosi Suzuki. Brit. 508,814, July 6, 1939. This corresponds to Fr. 838,761 (*C. A.* **33**, 6732[7]). The Mg compd. is preferably $Mg(OH)_2$.

Nickel. I. G. Farbenindustrie A.-G. Brit. 509,076, July 11, 1939. Ni poor in C is produced from crude Ni carbonyl (I) contg. Fe carbonyl by subjecting to thermal decompn. the I which has been purified previously to such an extent that it contains at most only 0.1% Fe, e. g., by dephlegmation or fractional distn.

Pretreating tantalum scrap for disintegration in the preparation of compact tantalum. N. P. Penkin. Russ. 55,886, Oct. 31, 1939. The scrap is made brittle by heating to incandescence in an atm. of H or N or a mixt. of these gases.

Regenerating spent pickle liquor or the like containing ferrous sulfate. Rowland P. Smith and John Belding (to Chemical Construction Corp.). U. S. 2,185,095, Dec. 26. A method of regenerating spent pickle liquor comprises (1) mixing with the spent pickle liquor an amt. of H_2SO_4 sufficient to restore it to its original free acid content and the quantity of $FeSO_4$ heptahydrate produced in step (5), (2) evapg. water from the resulting soln. and filtering off at temps. above 64° an amt. of $FeSO_4$ monohydrate chemically equiv. to the amt. of acid added, (3) recovering the S content of the $FeSO_4$ monohydrate as H_2SO_4 and returning the acid to step (1), (4) applying a vacuum to the filtrate and thereby cooling and concg. it to the point where the amt. of $FeSO_4$ heptahydrate will crystallize out that would be needed to maintain a satd. soln. in the filtration of step (2) if no other iron were present, (5) sepg. the $FeSO_4$ heptahydrate and returning it to step (1), and returning the resulting soln. to the pickling plant for reuse.

Cementation. P. A. Piterkin. Russ. 56,110, Nov. 30, 1939. Articles are cemented with coke breeze impregnated with liquid hydrocarbons (kerosene, fuel oil) and carbonates.

Cementation paste. G. L. Sorokin, B. A. Gutkin and P. K. Ivanov. Russ. 52,206, Nov. 30, 1937. The paste consists of the usual carburizers mixed into K oxalate or Na oxalate or in a 5% soln. of glue in water.

Carburizing metals such as steel. Wm. A. Darrah. U. S. 2,184,972, Dec. 26. App. is described, and a process of carburizing metals in a heated chamber by treating with a hot gaseous atm. contg. 2 different types of constituents, one constituent consisting of relatively inert gases and the second being active as a carburizing agent, the process including the step of introducing a hydrocarbon into the chamber and heating same by passing it into proximity to a source of heat so as to condition the hydrocarbon before it comes into contact with the metal to be carburized and then transferring the conditioned hydrocarbon into contact with the metal by thermal circulation.

Aluminothermic mixture for making permanent magnets. Hugh A. Howell (to Frank Raffles). U. S. 2,185,464, Jan. 2. A mixt. is used contg. Al, Ni, a compd. of Fe such as Fe_3O_4 and a compd. of Zr such as ZrO_2 in such amounts that after ignition and sepn. of the slag the remaining melt will contain Ni 5–40, Al 7–20, and Zr an effective amount up to 5%, the major part of the remainder being Fe, suitable for conversion into a permanent magnet upon solidification.

Cutting tools. Wm. P. Cottrell. U. S. 2,184,776, Dec. 26. In forming tools such as oil-well drilling tools, a piece of metal such as soft steel is coated with a ferro-W alloy, and other metal such as softer steel is cast to the coated piece of metal thus produced, and the article formed may be heat treated.

Preventing frothing in metal-cutting emulsions. P. I. Karasik and V. I. Dobashkin. Russ. 51,921, Nov. 30, 1937. The frothing of cooling emulsions used in metal cutting is hindered by addn. of $Fe_2(SO_4)_3$.

Malleable iron Axel G. E. Hultgren. U. S. 2,185,894, Jan. 2. A method of producing malleable iron from cast iron comprises making castings of white cast iron contg. Ni, Cr or Mn which increases the depth of hardening so that the castings will be hardened to sufficient depth to a largely martensitic-austenitic state by cooling from a temp. exceeding A_1 in a cooling medium not more efficacious than oil, and subjecting the castings to such a cooling and then to a malleabilizing anneal.

Detecting superficial flaws in materials such as cast iron or steel bars. Greer Ellis (to Magnaflux Corp.). U. S. 2,186,014, Jan. 9. A method of making superficial flaws in a rigid article of high-elastic limit capable of easy detection involves coating the article with a continuous adherent film such as a brittle lacquer having a rupture limit substantially lower than the elastic limit of the article and applying to the article a load of such magnitude and direction that the resulting stresses will exceed

the rupture limit of the film only above the flaws while remaining below the elastic limit of the rigid article.

Cleaning stainless steel and rustless iron surfaces. Charles J. Geng (to Wilson-Imperial Co.). U. S. 2,186,017, Jan. 9. H_3PO_4 is used (suitably in 10–20% aq. soln.) together with orthodichlorobenzene or methyl isobutyl ketone, etc.

Vessels such as steel dephlegmating towers formed of one metal and lined with different metal such as one more resistant to corrosion. Wayne A. Howard and Turner C. Smith (to Socony-Vacuum Oil Co.). U. S. 2,185,463, Jan. 2. A method of permanently placing an internally projecting supporting member such as a tray-supporting bracket within a metallic vessel having a liner of a metal different from that of the vessel involves abutting the supporting member directly against the internal face of the wall of the vessel; cutting away the liner to expose an annular area of the internal face around the periphery of the abutment; bringing the liner into contact with the internal face, and filling the annulus so formed with fused metal, whereby the supporting member and the liner are welded to the internal face of the vessel and to each other.

Transformer steel. V. S. Mes'kin and Yu. M. Margolin. Russ. 52,189, Nov. 30, 1937. The magnetic and technological properties of Si steel are improved by the introduction of Ti, V or Be together or individually in amts. less than 0.1%.

Cold-drawn steel tubing. Fred C. Raab and Edwin C. Wright (to National Tube Co.). U. S. 2,184,624, Dec. 26. A method for the manuf. of cold-drawn tubing of steel contg. Fe together with C 0.15–0.45, Mn 0.4–0.9, Ni 1–2, Cr 0.20–0.75 and Si 0.15–0.30%, a max. of 0.01% P and a max. of 0.05% S, to produce tubing of high machinability, involves heating the tubular blank to about 815–925°, holding the blank at such temp. for about an hr., pptg. the excess ferrite from the austenite in a uniformly dispersed condition and promoting the formation of carbide constituents in the form of coarse lamellar pearlite by slowly cooling the blank at a rate of about 11–28° per hr. to a temp. below 480°, and finally cold-drawing the blank to effect a reduction in area of 20–70% so as to form hard and soft layers which are freely machinable. Cf. *C. A.* **34**, 2317[9].

High-speed steels. Elmer B. Welch and Lewis G. Firth (to Firth-Sterling Steel Co.). U. S. 2,185,616, Jan. 2. Tool steels are formed contg. Mo 7.09–10, V 1.2–2.0, B 0.22–0.5, Cr 1.5 or less, Co 2.59–10 and C 0.5–1.0%. U. S. 2,185,617 relates to steels substantially free of Cr and contg. C 0.3–1.1, Si 0.05–1.0, Mn 0.1–1.0, V 0.25–2.5, Mo 5–12, B 0.05–0.5, and Co or Ni 0.5–20%. U. S. 2,185,618 relates to high-speed steels contg. Cr not in excess of 1.5% of the Fe content, together with C 0.28–1.04, V 0.24–2.8, Mo 4.72–9.61, Cu 0.09–4.01, B 0.05–0.8, and Fe 94.47–80.12%. U. S. 2,185,619 relates to generally similar high-speed steels contg. slightly less Fe and also contg. a small proportion of Ni.

High-speed tool steel. Elmer B. Welch and Lewis G. Firth (to Firth-Sterling Steel Co.). U. S. 2,185,006, Dec. 26. High-speed steels contain Fe 89.29–91.21, C 0.07–0.9, V 0.68–2.12, Mo 7.06–8.59, and B 0.09–0.81% (the B and C together not exceeding 1.13%, and the steel being free of Cr in excess of 1.5% of the Fe content).

High-tensile alloy steel. Wm. H. Hatfield (to Thos. Firth & John Brown Ltd.). U. S. 2,185,996, Jan. 9. A high-tensile alloy steel (various properties of which are given) contains Ni and Cr each 3–7%, Mo 2–5, and C 0.12% or less, and is air cooled from about 900° and subsequently tempered for an hr. and air cooled from the tempering temp.

High-manganese steel articles such as levers, brake shoe heads, etc. Frank T. Ward. U. S. 2,185,483, Jan. 2. App. is described, and a method of processing a mech. part composed of high manganese steel having a bore therein, which comprises forming the part of high manganese steel contg. about 11 to 14% Mn with an undersized bore therein and subjecting the part at the surface of the bore to pressure to size and harden it.

Making alloys of iron and steel. Casimer J. Head (to Metallurgical Development Co. Ltd.). U. S. 2,185,081, Dec. 26. A method is employed which includes prepg. a suitable bath of ferruginous molten metal, in any suitable type or kind of furnace supplying heat throughout the process, removing the oxidizing slag accumulated during the melting stage, and covering the metal bath with a fresh slag, composed of lime and fluorspar, to which a small quantity of ferrosilicon is added, introducing on to the surface of the metal bath relatively heavy molded blocks contg. one or more of the oxides of the alloying materials and a noncarbonaceous reducing agent, all in a comparatively fine state of division, being cemented together with the aid of slaked lime and water, and being of such d. as to penetrate the slag and come into direct contact with the surface of the molten metal of the bath, such molded blocks, after being air dried, being sprayed over with a milk of lime wash and allowed to dry, are then heated to above 900° for freeing them from any combined water formed by the chem. reaction upon air drying of the pugged mass of ore and lime.

Separating the component parts of alloys or of metal mixtures. Paul Kemp. Brit. 508,925, July 7, 1939. The constituents are sepd. by liquation, the mixt. of the constituent parts that are liquid and solid, resp., at the temp. at which liquation occurs being forced against a sepg. member pervious to the liquid constituents under a pressure of at least 500, and preferably at least 1000, atm., e. g., by means of compressed gas or mech. means.

Refractory hard alloy. V. I. Voloshin. Russ. 56,039, Nov. 30, 1939. Powd. Fe, Ni, Co and corundum are sintered together.

Antifriction alloy. V. E. Borisov. Russ. 51,989, Nov. 30, 1937. The alloy contains Zn 46–75, Pb 15–35, Al 6–20 and Cu 4–6%.

Aluminum alloys. I. G. Farbenindustrie A.-G. Brit. 508,975, July 10, 1939. Al alloys contain Zn 2–6, Mg up to 12, Cr 0.05–1 and, if desired, Mn up to 1%, the Mg exceeding by at least 3% that required for the formation of $MgZn_2$. Ca 0.05–1% may be added. Work pieces of the alloys may be heat-treated by homogenizing and subsequent aging at ordinary or elevated temps. below 150° to improve their mech. strength and resistance to intercrystn. and stretch corrosion. Cf. *C. A.* **33**, 7724[3].

Free-cutting aluminum alloys. Adolf Beck and Hans Bohner (to I. G. Farbenind. A.-G.). U. S. 2,184,692, Dec. 26. See Brit. 492,228 (*C. A.* **33**, 1653[9]). U. S. 2,184,693 relates to alloys of generally similar compn. except that they do not contain Si.

Aluminum alloys suitable for casting. Wm. E. Mansfield. U. S. 2,185,348, Jan. 2. Alloys of finer-grain structure, higher-tensile strength and better casting properties than otherwise similar alloys not contg. a W-group metal contain Al together with Sb 0.05–15% and W or V or a like metal up to 3%.

Copper alloys suitable for paper-pulp chests and other apparatus. Elmore S. Straug, Richard O. Farmer and Edward H. Koenig (to New Haven Copper Co.). U. S. 2,185,956, Jan. 2. A corrosion- and abrasion-resistant alloy is formed of Cu together with Si 1–5% and about 0.5% each of Ni, Fe and Mn. U. S. 2,185,957 (Elmore S. Strang and Richard O. Farmer, joint inventors) relates to an alloy suitable for like uses, which may contain Cu 95, Si 3.5, Ni 0.5 and Fe 1%, having a tensile strength of about 70,000–118,000 PSI, a yield-point range of about 30,000–65,000 PSI, a modulus of elasticity of about 16.6×10^6, and an elongation rage of from about 2 to 47% in 2 in. U. S. 2,185,958 (Elmore S. Strang and Edward H. Koenig, joint inventors) relates to an alloy contg. Si 3.5, Ni 1.0 and Cu 95.5%, having a tensile-strength range from about 65,000 to 118,000 PSI, a yield point range from about 18,000 to 78,000 PSI, a modulus of elasticity of 17.4×10^6, and an elongation range of from about 2 to 60% in 2 in.

Copper-aluminum alloys suitable for light reflectors. Willem Hermsen and Francis J. Delves. U. S. 2,184,716, Dec. 26. See Brit. 491,223 (*C. A.* **33**, 959[9]).

Copper-zinc-tin alloys containing manganese. Stephen F. Hackley (to Bridgeport Rolling Mills Co.). U. S.

2,185,809, Jan. 2. Cold-workable alloys of good toughness, ductility, spring quality, tensile strength and elec. cond. contain Cu 87–90, Zn 9–12, Sn 2–4 and Mn 2% or less, added as a flux.

Iron or iron alloys. I. G. Farbenindustrie A.-G. Brit. 509,024, July 10, 1939. These are manufd. from Fe-bearing residues obtained in the pressure hydrogenation of carbonaceous materials, particularly coals, with the use of masses contg. Fe as catalysts by removing oily matter from the residues by filtration, centrifuging or low-temp. carbonization, e. g., at 500°, in such manner that so much oily matter remains in the residue as is required for the reduction of the metal compds. contained therein and smelting the thus prepd. residues.

Cast iron alloys. Wm. A. Oubridge. Brit. 508,850, July 4, 1939. Cylinder liners of internal-combustion engines are made of cast Fe of austenitic structure contg. Ni 10–20 and Cr 2–4% and having a coeff. of expansion exceeding 0.000016 per 1°. Other elements, e. g., Al, Mo, Ti, V, W and (or) Zr up to a total of 6% may be added. Cu up to 9% may be substituted for an equiv. wt. of the Ni. Suitable alloys contain C 2.5–3.5, 2.8; Si 1–3, 2.0; S up to 0.14, 0.10; P 1.2, 0.8; Mn 0.4–2, 1.0; Ni 10–20, 14.0; Cr 2–4, 3; Cu 0, 6.0; Fe being the remainder in each case.

Magnetic alloys of zirconium suitable for permanent magnets. Peter P. Alexander (to Metal Hydrides, Inc.). U. S. 2,184,769, Dec. 26. A powd. alloy contg. Zr together with Ni, Fe or Co is heat treated at about 345–800° in order to give high magnetic permeability and retentivity.

Thermostatic element. Romaine G. Waltenberg (to H. A. Wilson Co.). Can. 387,019, Feb. 20, 1940. An iron alloy of high expansion coeff., contg. Ni + Co 17–20, Co 0.10 max., Cr 6–15, C 0.15 max., Mn 0.9–1, Si 0.15 max., S 0.02 max., P 0.02% max., is combined with an iron alloy of low expansion coeff., contg. Ni + Co 36–42, Co 0.4 max., Cr 5–9.5, C 0.15 max., Mn 0.50 max., Si 0.15 max., S 0.02 max., P 0.02% max. Cf. *C. A.* **33**, 3325[4].

Protective film on iron, steel and aluminum. E. I. Zabyvaev and I. I. Ershov. Russ. 56,037, Nov. 30, 1939. The metals are treated with a soln. of saltpeter, $CuCO_3$, Cr_2O_3 and H_2O at a temp. not over 115°.

Finishing the surfaces of metal articles such as zinc or brass castings, etc. Joseph Lupo, Jr. U. S. 2,185,262, Jan. 2. The articles are tumbled in a dry mass contg. vegetable-ivory chips, and abrasive material with lubricating and adhesive vehicles.

Apparatus for surfacing steel billets, etc., by the action of a blowpipe. James H. Bucknam (to Linde Air Products Co.). U. S. 2,186,096, Jan. 9. Various structural, mech. and operative details.

Use of phosphate coating solutions on ferrous metal surfaces. Gerald C. Romig (to American Chemical Paint Co.). U. S. 2,186,177, Jan. 9. A method of coating a ferrous metal surface by treating it with an aq. acid phosphate coating soln. where the surface is first cleaned with an alk. cleaning soln. includes the step of rinsing the surface after the cleaning operation with an aq. soln. having an acidity within the range pH 4.2 to 6 before treating it with the coating soln. Cf. *C. A.* **33**, 8166[7].

Use of molten metal (such as that for galvanizing) for coating pipes. Geo. T. Church (to Fretz-Moon Tube Co.). U. S. 2,184,610, Dec. 26. Various details of app. and operation.

Compositions for rustproof coating of metals such as iron. John C. Zimmer and Jack B. Crutchfield (to Standard Oil Development Co.). U. S. 2,184,952, Dec. 26. A hydrocarbon coating vehicle is used contg. at least 5% of an aldehyde-free unsatd. distn. residue of acids produced by the low-temp. liquid-phase catalytic oxidation of hydrocarbon wax at atm. pressure. An arrangement of app. is described.

Metal-blasting material. Gustave H. Kann (to Globe Steel Abrasive Co.). U. S. 2,184,926, Dec. 26. A material in the form of shot or grit, suitable for use in "sand blasting" machines, contains Fe together with C 2–4, Si 0.5–3, Mn 0.2–2, S 0.3 or less and P 0.05–2%, and is at least partially malleabilized from white iron and cooled at such a rate that its toughness is increased and its hardness is decreased to within a range from 125 to 500 on the Brinell scale.

Corrosion-resistant ferrous alloys suitable for casting. James A. Parsons, Jr. (to Durion Co.). U. S. 2,185,987, Jan. 2. Alloys contg. Ni 23–30, Cr 17–22, Si 0.5–2, Cu 3–5, Mo 2–4 and C up to 0.12%, the remainder being practically all Fe (the Mo always predominating over Si and both together not exceeding 5%) are resistant to corrosion, have good casting properties and good cold-bending properties as cast (a standard specimen as cast withstanding a cold bend of at least 90° without failure). Cf. *C. A.* **33**, 960[3].

Inhibiting rusting of ferrous metal surfaces such as those of plates, wires, etc. Wm. K. Griesinger (to Atlantic Refining Co.). U. S. 2,186,018, Jan. 9. There is applied to the surface a substantially nonsticky and nongummy film of viscous hydrocarbon oil substantially free from constituents tending to stain, corrode or react with the ferrous metal surface and contg. about 10% (more or less) of an alkyl stearate or naphthenate such as butyl stearate.

Filler material suitable for use in welding, etc. Arthur R Lytle (to Oxweld Acetylene Co.). U. S. 2,186,115, Jan. 9. Filler material contains Cu 62–47, Cd 1–6, Si 0.01–0.5%, the remainder being Zn. U. S. 2,186,116 relates to a filler material contg. Pb 8–18, Sn 5–12, Zn 8–15, Si 0.05–0.5%, the remainder being Cu. U. S. 2,186,117 relates to filler material contg. Cu 62–47, Cd 1–6, Ag 10% or less, Si 0.01–0.5%, the remainder being Zn.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Raw-material base for the organic chemical industry in the United States of America. I. G. Gershman. *Org. Chem. Ind.* (U. S. S. R.) **6**, 116–19(1939).—A review of the sources of raw materials and their methods of reworking based on the literature. Extensive bibliography.
Chas. Blanc

Synthetic organic chemicals; United States production and sales. Anon. U. S. Tariff Comm., Rept. No. **136**, 59 pp. (1938). G. G.

Physical properties of some purified aliphatic hydrocarbons. Donald B. Brooks, Frank L. Howard and Hugh C. Crafton, Jr. *J. Research Natl. Bur. Standards* **24**, 33–45(1940)(Research Paper No. 1271); cf. *C. A.* **34**, 1969[8]. —Four olefin and 7 paraffin hydrocarbons have been obtained in a high state of purity by careful fractionation. Eight of these were synthesized; two, heptane (I), and 2,2,4-trimethylpentane (II), were obtained from com. sources; and one, 2,3,4-trimethylpentane (III), was isolated from synthetic crude. Their consts. are given below in the order: compd., f. p., b_{760}, dt/dP (degrees/mm. Hg), n_D^{20}, n_D^{25}, dn/dt (20° to 25°) per degree, d_{20}, d_{25}, dd/dt (20° to 25°) (g./ml./degree). 3,3-Dimethyl-1-butene, −115.53°, 41.239°, 0.0397°, 1.37604, 1.37295, −0.000618, 0.65293, 0.64786, −0.001014; 2,3-dimethyl-1-butene, −140.1°, 55.615°, 0.0410°, 1.39022, 1.38724, −0.000596, 0.67801, 0.67322, −0.000958; 2,3-dimethyl-2-butene, −75.4°, 73.24°, 0.0414°, 1.4121, 1.4092, −0.00057, 0.7088, 0.7045, −0.00086; 2,3,3-trimethyl-1-butene, −111.40°, 77.874°, 0.0447°, 1.40292, 1.40004, −0.000576, 0.70501, 0.70054, −0.000890; 2,2-dimethylbutane, −100.06°, 49.731°, 0.0407°, 1.36864, 1.36592, −0.000543, 0.64902, 0.64432, −0.000940; 2,3-dimethyl-

butane, −129.79°, 57.999°, 0.0412°, 1.37490, 1.37212, −0.000556, 0.66150, 0.65699, −0.000921; 2,2,3-trimethylbutane, −25.059°, 80.879°, 0.0449°, 1.38947, 1.38683, −0.000528, 0.69000, 0.68576, −0.000848; 3-ethylpentane, −118.65°, 93.473°, 0.0446°, 1.39337, 1.39084, −0.000506, 0.69818, 0.69377, −0.000882; I, −90.60°, 98.424°, 0.0449°, 1.38764, 1.38511, −0.000506, 0.68368, 0.67943, −0.000849; II, −107.37°, 99.233°, 0.0465°, 1.39155, 1.38915, −0.000480, 0.69189, 0.68778, −0.000822; III, −109.97°, 113.391°, 0.0479°, 1.40431, 1.40193, −0.000476, 0.71903, 0.71507, −0.000791.

Amos G. Horney

Chemistry and mechanism of pyrolysis of ethylene. (Method for production of technically valuable butadiene.) M. Schultze and G. R. Schultze. *Oel Kohle Erdoel Teer* 15, 193–8, 215–20, 233–41; *Kautschuk* 15, 182–5, 195–201 (1939).—The pyrolysis of C_2H_4 has been studied in a statical system at 400–680°/300–1156 mm. and in a flow system (admixed with N_2) at 777–884°/1 atm. (reaction time 0.2–1.5 sec.). The reaction vessels were of SiO_2. The principal reactions were $2C_2H_4 = C_4H_8$ in the statical expts. and $2C_2H_4 = C_4H_6 + H_2$ in the flow expts. The first reaction was of the 2nd order; it was strongly catalyzed by traces of O. Analysis of the results on the basis of the Arrhenius equation showed the existence of a large steric factor. Among the other reaction products were C_2H_2, C_6H_6 and H. A scheme for the reaction mechanism is suggested, based on the above results and on supplementary expts. on the decompn. of various mixts. (e. g., $C_2H_4 + C_4H_6$ and $C_2H_2 + C_2H_4$) in the flow app. The thermal decompn. of C_2H_4 offers a means for the tech. production of butadiene. B. C P. A.

Influence of the substituents on the velocity of catalytic hydrogenation of certain trisubstituted ethylenes in the presence of platinum. B. A. Kazanskiĭ and G. T. Tatevosyan. *J. Gen. Chem.* (U. S. S. R.) 9, 1458–64(1939). 1-Methyl-2,2-diethyl- (I), 1,2-dimethyl-1-phenyl- (II), 1-methyl-2,2-diphenyl- (III) and triphenylethylene (IV) were prepd. by known methods. The individual ethylenes and equimol. mixts. of I with II, III and IV were hydrogenated in 96% alc. in the presence of Pt black at room temp. by the method described in an earlier paper (*C. A.* 33, 4204⁴). The graphic results show that the velocity of hydrogenation of trisubstituted ethylenes decreases with increasing no. of aryl substituents in the mol. The drop in velocity is particularly sharp with the introduction of a 2nd aryl substituent. The hydrogenation of mixed hydrocarbons proceeds simultaneously. However, because of the different character of substituents and the resulting difference in the hydrogenation velocity of the individual hydrocarbons and the distribution of H between the components of mixts., the reaction shows some selectivity, which becomes more pronounced with greater no. of Ph substituents in the 2nd component. Chas. Blanc

Determination of the specific gravity of vinylacetylene. K. Kuchinskaya and Anitina. *Shornik Trudov Otdynogo Zavoda im. S. V. Lebedeva* 1938, 26–7; *Khim. Referat. Zhur.* 2, No. 5, 65(1939).—The detn. of d. of pure vinylacetylene (b. 5°) was performed in a sealed dilatometer. The following data were obtained for d. −10°, 0.7187; −5°, 0.7128; 0°, 0.7067; 5°, 0.7010; 10°, 0.6954; 15°, 0.6895; 20°, 0.6835; 25°, 0.6780; 30°, 0.6679.

W. R. Henn

The theory of the structure and the questions of the dynamics of organic molecules. A. E. Favorskiĭ. *Uchenye Zapiski Leningrad. Gosudarst. Univ.* 3, No. 17, 171–80(1937).—A discussion of advances made in the field of structural rearrangements, isomerism, tautomerism, etc. A successful utilization on an industrial production scale of the synthesis of butadiene rubber starting with EtOH is described. A modified German method for the synthesis of isoprene rubber was developed in which the expensive $NaNH_2$ was replaced with KOH, and the yield of the alc. increased from 35 to 85% of the theoretical yield. By means of the electrolytic hydrogenation of $Me_2C(OH)C{:}CH$ the isoprene rubber is being produced on a semi-industrial scale with a yield of dimethylvinylcarbinol up to 95%, while by hydrogenation a higher-boiling fraction is obtained (1-isobutenylcarbinol). It was found that an equil. isomerism exists between these 2 substances (dimethylvinylcarbinol and 1-isobutenylcarbinol). A no. of investigations were devoted to the transformations of α-keto alcs. The process of alc. fermentation is explained as a no. of reactions of simultaneous oxidations and reductions. A scheme of successive transformations is given.

W. R. Henn

Hydrolysis of tertiary alkyl halides. Nicholas D. Cheronis. *Trans. Illinois State Acad. Sci.* 32, No. 2, 101–2(1939).—Measured amts. of *tert*-amyl halides were heated at 100° for 100 hrs. in sealed ampoules, and the resultant mixts. extd. by hexane. The org. layer was analyzed for unreacted halide by shaking with standard $AgNO_3$ soln. and for olefin by titrating with standard bromide-bromate soln. About 60% of the chloride and bromide was hydrolyzed, and about 50% of the iodide. Alkali increases the yield of olefin, but does not repress entirely the formation of carbinol. Equil. mixts. seem to be formed, since the resultant products are strongly affected by excess water. Further the resultant mixt. can be approached by heating together olefin, acid and water. Some of the results are unexpected, and it is concluded that no single generalization can be made about the hydrolysis of tertiary halides. J. H. Reedy

The iodine-sensitized decomposition of methyl alcohol. G. K. Rollefson and Warren Garrison. *J. Am. Chem. Soc.* 62, 588–90(1940).—The I-sensitized decompn. of MeOH has been studied at 325°. The net over-all reaction may be represented by the equation $3MeOH = 2CH_4 + CO + 2H_2O$. This is the resultant of 2 parallel reactions, one an oxidation of the alc. by I to CO, the other a reduction by HI to CH_4. These reactions are represented by the equations $MeOH + 2I_2 = CO + 4HI$ and $MeOH + 2HI = CH_4 + I_2 + H_2O$. Tables are given for the distribution of I and for the amts. of CH_4 and CO present during the reaction. A. B. Garrett

Preparation of higher alcohols by the Grignard method. Victor S. Webster and Arnold E. Schaefer. *Proc. S. Dakota Acad. Sci.* 19, 124–9(1939). Light-yellow waxy cetyl bromide (I), m. 10–17°, prepd. in 80% yield by refluxing 320 g. cetyl alc. with 1056 g. const.-boiling HBr for 4 hrs., was converted to the Grignard compd. and treated with gaseous HCHO (prepd. by heating paraformaldehyde on an oil bath at 260°) to form waxy heptadecyl alc. (II), m. 53°, in 53% yield (on basis of 160 g. I, 390 cc. anhyd. ether and 20 g. Mg powder with a trace of I). II (18 g.), refluxed with 54 g. const.-boiling HBr, gave the yellow waxy bromide (III), m. 28°, in 82% yield. III (17 g.) in 33 cc. Et_2O was added to 2.5 g. Mg powder in 35 cc. ether, and HCHO from 9 g. paraformaldehyde passed into the mixt., yielding waxy octadecyl alc. (IV), m. 58°, in 64% yield. IV (6 g.) refluxed with 27 g. const.-boiling HBr gave the yellow waxy bromide, m. 52°, in 79% yield. Forms, yields and m. ps. of the iodides prepd. by the method of Gascard (*C. A.* 16, 48) and acetates prepd. by the method of Meyer and Reid (*C. A.* 27, 2420) were resp.: cetyl, yellow wax, 76%, 23°, white wax, 42%, 21–2°; heptadecyl, yellow-orange wax, 78%, 33–34°, white wax, 48%, 24–5°; octadecyl, yellow-orange wax, 73%, 33°, white wax, 56%, 27°. Creams contg. 8 g. stearic acid, 2 g. borax, 16 cc. olive oil and 80 cc. water are stabilized with 1% of heptadecyl or octadecyl alc.

George Ayers

Preparation of higher tertiary alcohols. V. V. Korshak. *J. Gen. Chem.* (U. S. S. R.) 9, 1470–2(1939).—A mixt. of 20 g. cetyl bromide, 10 g. Et stearate and 1.6 g. Mg in 100 ml. ether was refluxed 20 hrs. and filtered hot. Fractional recrystn. of the filtrate ppt. from ether, petr. ether and alc. gave dotriacontane, m. 64–5°, *dihexadecylheptadecylmethanol*, $(C_{16}H_{33})_2C(OH)C_{17}H_{35}$, m. 45–6°, and a product, m. 39–40°, which was not investigated. Refluxing 1 hr. the Grignard reagent from 51 g. PhBr and 9 g. Mg in 100 ml. ether with 33 g. Et stearate in 50 ml. ether and decompg. the reaction mixt. with aq. NH_4Cl gave *diphenylheptadecylmethanol*, $Ph_2C(OH)C_{17}H_{35}$, m. 51–2°. When vacuum-distd. it cleaved H_2O and gave *1,1-diphenyl-2-hexadecylethylene*, $C_{16}H_{33}CH{:}CPh_2$, m. 6°, b_{10} 228–30°, d_4^{25}

0.9297, n^{25}_D 1.5295, M. R.$_D$ 134.2; *dibromide*, m. 34°. Condensation of 32 g. PhBr and 5 g. Mg with 25.3 g. stearone in 300 ml. (iso-Am)$_2$O gave *phenyldiheptadecylmethanol*, $PhC(OH)(C_{17}H_{35})_2$, m. 46–7°; *bromide*, m. 70–1°. Chas. Blanc

Chemistry of substituted acetylenes and their derivatives. XXXVII. Addition of hydroxy compounds to acetylenic alcohols. J. F. Froning and G. F. Hennion. *J. Am. Chem. Soc.* **62**, 653–5(1940); cf. *C. A.* **34**, 2321⁹.— $Me_2C(OH)C{:}CH$ (I) and MeOH with the HgO-BF_3 catalyst (4–5 g. red HgO, 5 ml. Et_2O-BF_3, 5 ml. MeOH and 1–3 g. Cl_3CCO_2H), heated 3 hrs. at 45–55°, give 80% of *3,3-dimethoxy-2-methyl-2-butanol* (II), b_{50} 81°, n^{25}_D 1.4248, d^{20} 0.974, and 4.4% of *2,5-dimethoxy-2,3,3,5,6,6-hexamethyl-1,4-dioxane* (III), $Me_2C.C(OMe)Me.O.CMe_2.C(OMe)Me.O$, m. 107°. Hydrolysis of II or III with dil. H_2SO_4 gives $Me_2C(OH)Ac$, b_{50} 65°, b_{760} 139°, n^{25}_D 1.4150, d^{20} 0.950. When boiled with MeOH contg. a trace of acid III gives II. I and AcOH with the above catalyst give 49% of 2-acetoxy-2-methyl-3-butanone (IV), b_{50} 93°, n^{25}_D 1.4180, d^{20} 1.008 (Scheibler and Fischer, *C. A.* **17**, 1419). $Me_2C(OH)C{:}CC(OH)Me_2$ and MeOH or AcOH with the HgO-BF_3 catalyst give 77–8% of 2,2,5,5-tetramethyltetrahydro-3-furanone, b_{50} 71°, n^{25}_D 1.4197, d^{20} 0.9255 (semicarbazone, m. 190° (Dupont, *C. A.* **8**, 1579); the triple bond is hydrated before the cyclization. Heating 351.5 g. II and 0.1 g. *p*-$MeC_6H_4SO_3H$ at 150–80° for 8 hrs. gives 110 g. distillate, b. 64° (MeOH); neutralization of the residue and distn. gives 115 g. of a mixt., b_{750} 123–65°, which yields MeOH, V and VI on further distn. A 2nd fraction (67 g.), b_{50} 78–82°, gives on redistn. *1,3,3,4,6,6-hexamethyl-2,5,7-trioxabicyclo[2.2.1]heptane* (V), $Me_2C{<}O{>}CMe_2$ (O bridges), b_{750} 165°, n^{25}_D 1.4199, d^{20} 0.972; this was also prepd. by S. and F. by the action of P_2O_5 upon IV but they gave it the formula $(O.CMe_2.CMe)_2O$; formula V is favored by the parachor measurements and by the fact that it is unchanged after prolonged boiling with MeOH contg. *p*-$MeC_6H_4SO_3H$. A 3rd fraction b_{50} 110–12°, n^{25}_D 1.4533, d^{20} 0.979, is the dioxane, $MeOCMe.CMe_2.O.C(:CH_2).CMe_2.O$ (VI). In the presence of acid VI adds MeOH to give III. When heated with a trace of acid III loses MeOH to give V and VI. C. J. West

Synthesis of isopropyl ether. VII. Dehydration of isopropyl alcohol into isopropyl ether in an atmosphere of propylene under pressure and some supplementary experiments. Masaharu Katuno. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 422–4(1939); cf. *C. A.* **33**, 6237¹.—A mixt. of H_2SO_4 and iso-PrOH was placed in an enameled beaker and inserted in an agitating autoclave. A definite amt. of C_3H_6 was liquefied on the surface of the mixt. The autoclave was heated for several hrs. and then allowed to cool. C_3H_6 formed was collected in a gas holder and measured. The highest yield of $(iso\text{-}Pr)_2O$, 62% of theory and 16% greater than without the addn. of C_3H_6, was obtained at 140° for 6 hrs. with a ratio of iso-PrOH:H_2SO_4 of 10:1 and a final pressure of 27 atm. The recovery of iso-PrOH was also increased from 18% to 20–21%. Decreasing the space in the autoclave by increasing the reaction mixt., without compressing in addnl. C_3H_6 also increased the yield of $(iso\text{-}Pr)_2O$ to 51–52% of theoretical. These results support the reaction mechanism previously postulated. Mark Plunguian

Synthesis of the sodium salt of tetradecamethylenedisulfonic acid. Gilbert C. H. Stone. *J. Am. Chem. Soc.* **62**, 571–2(1940); cf. *C. A.* **30**, 2918⁴.—The earlier work showed that the synthesis of the C_{10} disulfonate by the Strecker reaction required 168 hrs. for complete conversion; to avoid the long period of heating which would be necessary for the higher members, other methods were sought. The dixanthate was found to be a suitable intermediate. $(CH_2)_{14}(OH)_2$ and HBr give 65% of *tetradecamethylene dibromide* (I), b_{2-3} 172–5°. I (402 g.) in 2 l. hot EtOH was added slowly to 480 g. of K ethylxanthate in 2 l. EtOH and refluxed with stirring for 24 hrs. Removal of the EtOH and purification of the ether soln. give a yellow liquid which was dissolved in dioxane, H_2O added to turbidity and then in alternate small portions 2720 g. Br and 1000 ml. H_2O; after several hrs. the Br and HBr are removed on the steam bath and by repeated distn. under reduced pressure, $AgNO_3$ is added and the ppt. is extd. with hot H_2O to remove the Ag disulfonates; the Ag is removed as Ag_2S and the soln. neutralized with NaOH, giving 54% of *Na tetradecamethylenedisulfonate*, with a grayish cast and not very sol. in H_2O; the salt showed no tendency to hydrolyze. C. J. West

2-Aminobutane, di-*sec*-butylamine and butyl-*sec*-butylamine and their preparation in the optically active state. Andrée Fleury-Larsonneau. *Bull. soc. chim.* **6**, 1576–82 (1939).—The catalytic reduction of 80 g. MeCOEt in 200 g. of 10% NH_4OH in the presence of a divided Ni catalyst (or Raney Ni) contg. 10 g. of Ni, at a pressure of 25 kg. at 60–120° in a rocking stainless-steel lined autoclave gave 54 g. of 2-aminobutane (I), b. 66°, and 5.4 g. of di-*sec*-butylamine (II), b. 132–4°, in an over-all yield of about 80%. By a modification of the method of Thomé (*Ber.* **36**, 582 (1903)) I was resolved. I (48 g.) dild. with 50 cc. H_2O was treated with 30% *d*-tartaric acid until neutral to litmus and with an equal addnl. amt. to form the bitartrate. The mixt. was evapd. down to 265 g. and, on cooling, gave 125 g. of bitartrate. Two recrystns. from hot H_2O gave 52 g. of hard brilliant crystals of the *d*-bitartrate (III). Decompn. of III with boiling NaOH and distn. gave 15 g. of *d-2-aminobutane*, $[\alpha]_D$ 7.4°. The mother liquors from III were neutralized with racemic acid and the soln. was evapd. down to 300 g., yielding 100 g. of crystals. These crystals were recrystd. twice from hot H_2O, producing mother liquors (IV) and 54 g. of crystals, and, again, mother liquors (V) and 30 g. of crystals (VI). Concn. of IV and V gave 39 and 30 g. of crystals, which on recrystn. and seeding with VI, gave 25 g. of VI. VI gave an amine, $[\alpha]_D$ −5.0°, of which 12 g. on neutralization with 20% *l*-tartaric acid gave fine, hard brilliant crystals, yielding 8 g. of *l-2-aminobutane*, $[\alpha]_D$ −7.1°. A mixt. of 18 g. of 2-bromobutane and 10 g. I was heated for 15 hrs. in the presence of 15 g. abs. alc. After neutralization with H_2SO_4, the product was distd. free from unreacted bromobutane and alc. The sulfates were decompd. with NaOH and extd. with ether. Distn. of the residue from the ext. gave unreacted I and then 12 g. of colorless II; picrate, m. 65°. A similar prepn. from bromobutane and I by heating for 4 hrs. in alc. gave butyl-*sec*-butylamine (VII), b. 146–8°; picrate, m. 105°. From *d*-2-aminobutane the *d-forms* of II and VII, $[\alpha]_D$ 23.6° and 16.1°, resp., were also prepd. C. R. Addinall

Action of nitrous acid on formaldehyde. Henrietta Margaret Halliday and Thomas H. Reade. *J. Chem. Soc.* **1940**, 142–3.—In an attempt to repeat Vanino and Schinner's expts. (*C. A.* **7**, 1461) in which they reported that HNO_2 and HCHO give CO_2, H_2O and N_2, it was found that 94% of the gaseous products consist of NO and 6% of N; nitrate from 29 to 41% remained in soln. The total amt. of gas was approx. const. whether collected over Hg, H_2O, $Ca(OH)_2$ or 50% KOH and corresponded to about 66% of the HNO_2 used. The CO_2 formed was less than 1/50 of that demanded by V. and S.'s equation. Almost the whole of the HCHO is recovered unchanged, not more than 3.8% of it being decompd. or lost in any expt. The reaction therefore consists almost entirely in the thermal decompn. of HNO_2 into HNO_3, NO and H_2O. C. J. West

The chlorination of carbon chains. Max I. Bowman. *Proc. S. Dakota Acad. Sci.* **19**, 112–14(1939).—Chlorination of PrOH in the presence of catalysts such as $AlCl_3$, Mg turnings or chromyl chloride below 45–50° gave $MeCHCl\text{-}CHO$ (I) as the chief product, as well as an acetal, b_{23} 105–8°, of unknown constitution but possibly derived from $ClCH_2CH_2CHO$ (II). Sunlight had a varied effect on the reaction, II possibly being formed in one instance. Electrolytic chlorination of PrOH gave only a small yield of I

and no II. Chlorination of BuOH (1) in sunlight gave a chloro acetal of unknown compn. and (2) at low temp. gave, besides polymers, a monochlorobutyraldehyde (III), b. 105–6°. The di-Et acetal of III, b_{15} 102–5°, was less stable than the di-Et acetal of $MeCHClCH_2CHO$. Chlorination of the di-Et acetal of $MeCH_2CH_2CHO$ gave a fairly stable mono-Cl deriv., b_{15} 98–101°, b. 182–5°, in which the Cl possibly has the γ-position, as well as small amts. of other isomeric products. George Ayers

Physical properties and chemical constitution. V. Alkyl ketones. David M. Cowan, Geo. H. Jeffrey and Arthur I. Vogel. *J. Chem. Soc.* **1940**, 171–6; cf. *C. A.* **33**, 8180[8]; **34**, 1625[8].—Details are given of the elec. furnace used in the prepn. of the ketones and of the prepn. of the *MnO catalyst* by absorption of $MnCO_3$ on pumice and heating in a N stream at 400–50° for 8 hrs. One l. of acid is circulated over the catalyst in from 72 to 94 hrs. $EtCO_2H$ (I) gives 59% Et_2CO (II); $PrCO_2H$ (III) gives 50% of Pr_2CO (IV); 8 mols. AcOH (V) and 4 mols. III give 31% Me_2CO (VI), 35% AcPr (VII) and 16% IV; 4 mols. each of V and III, 32% VI, 34% VII and 19% IV; 2 mols. V and 6 mols. III, 15.5% VI, 42% VII and 31% IV; 6 mols. V and 2 mols. III, 43% VI and 44% VII; 2 mols. V and 4 mols. III, 21% VI, 44% VII and 27% IV; 8 mols. I and 4 mols. III, 59% II, 49% EtCOPr (VIII) and 15% IV; 4 mols. each of I and III, 57% II, 54% VIII and 29% IV; 2 mols. I and 4 mols. III, 21% II, 41% VIII and 25% IV; 2 mols. I and 6 mols. III, 31% II, 66% VIII and 30% IV; 6 mols. I and 2 mols. III, 62% II and 18% VIII. AcBu and AcAm could not be prepd. by this method because of the production of resinous compds. The fraction of the ketones b. over 1–2° was purified through the semicarbazone and the ketone liberated with $(CO_2H)_2$. *n* is given for C, D, F and G′ (in this order); values are given for R_L for C, D, F and G′ and for G′-C and F-C; d. and γ are given for 3 or 4 temps., from which *P* (parachor) is calcd.; the no. in parentheses after γ is the temp. coeff. In each case the m. p. of the semicarbazone is given. VI, b_{762} 56°, *n* 1.35827, 1.36023, 1.36190, 1.36818, d_4^{20} 0.7960, γ_{20} 23.90 (0.10) (other values for d. and γ at 20°), *P* 161.6. AcEt, $b_{762.5}$ 81°, *n* 1.37683, 1.37881, 1.38333, 1.38712, d. 0.8058, γ 24.50(0.10), *P* 199.5. II, b_{751} 102°, *n* 1.39012, 1.39220, 1.39702, 1.40064, d. 0.8138, γ 25.29(0.11), *P* 237.4. VII, b_{756} 102°, *n* 1.38815, 1.39018, 1.39511, 1.39846, d. 0.8089, γ 24.82(0.11), *P* 238.0. VIII, b_{760} 125°, 1.39844, 1.40072, 1.40563, 1.41064, d. 0.8118, γ 25.54(0.11), *P* 277.3. IV, b_{767} 145°, *n* 1.40465, 1.40692, 1.41185, 1.41568, d. 0.8145, γ 25.38(0.10), *P* 315.1; AcBu, b_{757} 127.5°, *n* 1.39861, 1.40072, 1.40585, 1.40943, d. 0.8095, γ 25.43(0.10), *P* 277.5; iso-BuAc, b_{766} 118.5°, *n* 1.39352, 1.39562, 1.40064, 1.40420, d. 0.7978, γ 23.64(0.09$_5$), *P* 276.5. AcAm, b_{766} 151°, *n* 1.40640, 1.40860, 1.41380, 1.41755, d. 0.8111, γ 26.60 (0.10), *P* 319.1. Me hexyl ketone b_{758} 175°, *n* 1.41309, 1.41536, 1.42058, 1.42409, d. 0.8179, γ 25.73(0.07$_5$), *P* 355.7. $(iso\text{-}Bu)_2CO$, $b_{760.5}$ 168°, *n* 1.40990, 1.41206, 1.41727, 1.42109, d. 0.8053, γ 24.09(0.08$_5$), *P* 391.6. The chief feature of these results is the steady increase in the *P* difference for CH_2 in passing from VI to AcAm (37.9 to 41.6); this may be due largely to the Thorpe-Ingold valency deflexion effect. C. J. West

The reduction of aliphatic acid amides under high pressure. I. Sei-iti Ueno and Sin-itiro Takase. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 409–10(1939)(in German).—Me laurate, b_{15} 140–4°, heated in an autoclave with 33% NH_4OH, gives the amide (I), m. 98° after recrystn. from alc. Myristoyl and palmitoyl chlorides, treated with ammonia, gave the corresponding amides (II and III), m. 102–3° and 103–4°. Reduction of I, II and III, resp., in dioxane by Adkins' method (*C. A.* **26**, 2828) in the presence of $CuO\text{-}Cr_2O_3\text{-}BaO$ catalyst under 96–100 atm. initial and 203–210 atm. max. H pressure at 240–310° gave products consisting mostly of the corresponding secondary amines (didodecylamine, m. 51–3°; ditetradecylamine, m. 56–8°; and dicetylamine, m. 64–5°), NH_3 and possibly very small amts. of the corresponding primary amines. The formation of secondary amine is explained by: $RCONH_2 + 4H \rightarrow RCH_2NH_2 + H_2O$; and $2RCH_2NH_2 \rightarrow (RCH_2)_2NH + NH_3$, the 2nd reaction being more rapid than the first. George Ayers

Synthesis of acetylene γ-glycols. A. Babayan, B. Akopyan and R. Gyuli-Kevkhyan. *J. Gen. Chem.* (U. S. S. R.) **9**, 1631–2(1939); cf. *C. A.* **34**, 1616[9].—Preliminary expts. showed that the method of Favorskiĭ (*J. Russ. Phys.-Chem. Soc.* **1902**, 242) of alk. condensation of C_2H_2 and ketones to alcs. can be used in the prepn. of acetylene γ-glycols in good yields. The synthesis is effected by treating 10 g. ketone and 30 g. KOH in 100 ml. ether at 9–10° with 14 l. C_2H_2 in 1–2.5 hrs. and hydrolyzing the reaction mixt. the next day with H_2O. The reaction mixt. is freed from the ether and fractionated. The reaction with Me_2CO gave 59.6% *2,5-dimethyl-3-hexyne-2,5-diol*, m. 94–5°, and some butynol. MeCOEt gave 43% *3,6-dimethyl-4-octyne-3,6-diol*, m. 54°, and pentynol. Cyclohexanone gave 38% *bis(hydroxycyclohexyl)acetylene*, m. 105–6°, and (hydroxycyclohexyl)acetylene. C. B.

The reaction between acetylenedimagnesium dibromide and carbonyl compounds. Yu. S. Zal'kind and S. M. Labuzov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1525–32(1939). —The influence of the structure of CO compds. on the condensation of aldehydes and ketones with $(BrMgC{:})_2$ (I) in the synthesis of acetylene γ-glycols by the Iotzich method is studied. To this end, I, prepd. from 2 g. Mg, 12 g. EtBr and 100 ml. ether, is treated at 0° with a definite quantity of an aldehyde and ketone for measured periods of time and the reaction mixt. is decompd. with H_2O contg. H_2SO_4. The vol. of liberated C_2H_2 gives the amt. of unaltered I and indirectly the C_2H_2 used in the reaction. The exact content of I in the reagent was detd. by expelling the ether and decompg. the residue with H_2O. It was 915 ± 10 ml. C_2H_2, corresponding to 98.06% I. This figure was used in calcg. the results of the condensation reactions. Furthermore, since some C_2H_2 is dissolved by ether in the I reagent, its mean content was detd. by decompg. the reagent with water without the preliminary removal of the ether and heating the mixt. on a water bath. A vol. of 1249 ml. C_2H_2 was collected or 334 ml. in excess of the amt. liberated in the decompn. of I reagent with the previous expulsion of the ether. This C_2H_2 amt. was deducted from the C_2H_2 formed in the decompn. of the condensation reaction mixt. In the condensation with Me_2CO, MeCOEt, MeCOPr, Et_2CO, MeCOPh and Ph_2CO the reaction proceeds rapidly in the first 15 min. with the decompn. of 56.63% I and reaches a max. of 57.8% in 1 hr. This limit is not exceeded by longer duration of the reaction (4 hrs.) or by the use of a large excess of ketones (10 times). In the presence of I excess the condensation proceeds nearly quantitatively. The results show that the reaction is not reversible, hence the incomplete condensation is not caused by a reaction equil. in conformity with the law of mass action. It is probable that the reaction stops because of the occlusion of I by the insol. Mg complex formed in the reaction. The reaction proceeds in 2 stages: $Me_2CO + I \rightarrow Me_2C(OMgBr)C{:}CMgBr$; $Me_2C(OMgBr)C{:}CMgBr + Me_2CO \rightarrow [Me_2C(OMgBr)C{:}]_2$. This is confirmed by the formation of a glycol (tetramethyl-2-butyne-1,4-diol) and alc. $(Me_2C(OH)C{:}CH)$. In general, the velocity of condensation decreases with increasing mol. wt. of ketones. Aldehydes (AcH, EtCHO, PrCHO and BzH) react with I more rapidly to a max. of 70.16% decompn. (AcH). Chas. Blanc

The interaction of sodamide with carbonyl compounds incapable of enolization. L. Kh. Freĭdlin, A. I. Lebedeva and N. A. Kuznetsova. *J. Gen. Chem.* (U. S. S. R.) **9**, 1589–97(1939); cf. *C. A.* **33**, 8566[6].—The investigation of the interaction between $NaNH_2$ and carboxylic acids and ketones in the absence of a solvent is continued with higher ketones of the aliphatic, aromatic and terpene series. Again the reaction resulted in the formation of $NaHCN_2$, corresponding hydrocarbons and H. The reaction with the compds. in which the CO group is linked with a metal ($Fe(CO)_5$ and $W(CO)_6$) and with N ($CO(NH_2)_2$ and $CO(HNPh)_2$) formed $NaHCN_2$ and metal, NH_3 and $PhNH_2$, resp. The mechanism of the reactions is explained according to the general equations given in earlier papers (*C. A.* **32**, 1651[7], 9040[8]). The solid ketones were fused with Na-

NH_3 and volatile ketones were passed over $NaNH_2$ in an elec. furnace. The exothermic reactions were regulated to prevent excessive decompn. $(Me_3C)_2CO$ at 220° gave 33% Me_3CH. β-Benzopinacolone at 200° gave 80.88% Ph_3CH and C_6H_6; if the solid reaction product is reworked with C_6H_6 instead of PhMe, it forms the complex compd. $Ph_3CH.C_6H_6$, m. 77–8°. Michler's ketone at 180° formed 85% $PhNMe_2$. The reaction with fenchone at 280° afforded 36% of 1-methyl-3-isopropylcyclopentane, b_{762} 137–8.5°, d_4^{20} 0.7771, n_D^{20} 1.4278 M.R.$_D$ 41.74. It is identical with the product obtained from dihydrocamphorone by Kazanskiĭ (cf. *C. A.* **24**, 75). The reaction with Ph_2CO at 120° failed to give the expected Ph_2CH_2. $(CO_2Et)_2$ does not react at 100°. At 215° it gave H and $NaHCN_2$. Evidently the McONa is formed and decompd. in the reaction. HCO_2Et acts analogously. Urea at 140° formed NH_3, and $(PhNH)_2CO$ at 235° gave 26.6% $PhNH_2$. $Fe(CO)_5$ is completely decompd. at 156°, giving Fe, 85.7% H and 14.3% CO. $W(CO)_6$ is decompd. at 215° with a greater proportion of CO in the gaseous reaction products as the result of a more drastic thermal decompn. Chas. Blanc

Possible existence of polyiodides in mixed alcoholic solutions of iodine and 1,3-bis(dimethylamino)-2-propanol dimethiodide. Mario Covello. *Ann. chim. applicata* **29**, 187–9(1939); cf. *C. A.* **31**, 2168[7].—Absorption spectra of solns. of $Me_3N(I)CH_2CH(OH)CH_2NMe_3I.I_4$, $C_9H_{24}ON_2I_2.I_6$, $C_9H_{24}ON_2I_2.I_8$ show more and more the absorption of I in soln., giving evidence of increasing dissocn. on dilu. A. W. Contieri

Synthesis of the choline ester of β-glycerophosphoric acid. Herbert Arnold. *Ber.* **73B**, 87–90(1940).—Contardi and Ercoli (*C. A.* **27**, 3488, 4258) found that the 2 fat acid residues of lecithin can be split off stepwise by lecithases, leaving choline glycerophosphate (I). This fat-free component of lecithin they were able to isolate only in impure form, however, and for the study of its physiol. properties its prepn. in pure form by synthesis was therefore desirable This was effected by treating di-Ag β-glycerophosphate with $BrCH_2CH_2NMe_3Br$ in hot alc. I seps. from abs. alc., after addn. of a little dry ether to turbidity, in the ice chest in needles, m. 104–5° after careful drying over P_2O_5 at the temp. of boiling CH_2Cl_2, readily absorbs moisture from the air and forms in water a soln. with pH 4.2; $CdCl_2$ in alc. splits off the choline group and gives a ppt. of a Cd glycerophosphate. Di-Ag α-glycerophosphate with $BrCH_2CH_2NH_3Br$ also gave a product which in its solubilities, hygroscopicity and m. p. (sinters 60°, m. 80–90°) was quite similar to the colamine glycerophosphate obtained by Feulgen and Bersin (*C. A.* **33**, 8635[7]), but it could not be crystd. and therefore did not give satisfactory analytical results (found, P 12.55, N 6.57%; calcd. for $C_5H_{14}O_6NP$ 14.42, 6.52; for $C_5H_{14}O_6N$-P.H_2O 13.32, 6.01). The activity of synthetic I on the frog heart and the cat blood pressure is about 1/1000th that of acetylcholine (II), i. e., equal to that of free choline. On the intestine and skeletal muscle it also acts qualitatively like II but quantitatively much less powerfully. On the leech a concn. of 10^{-5} of I has the same effect as a concn. of 10^{-8} of II; on heating 2 min. at 100° the activity increases 3- to 4-fold but decreases greatly on further heating for 15–30 min. The initial increase in activity may be due to a change from the endo-salt form $(HOCH_2)_2CHOPO.O.CH_2.CH_2.NMe_3.O$ to the hydrated form $(HOCH_2)_2CHOPO(OH)OCH_2CH_2NMe_3OH$. Toward alkalies, I is quite resistant as regards physiol. activity. C. A. R.

Chaulmoographosphatides. Herbert Arnold. *Ber.* **73B**, 90–4(1940).—The chaulmoogra oil prepns. used in the treatment of leprosy are for the most part water-insol. esters of the chaulmoogric and hydnocarpic acids present in the oil. It seemed desirable, in order to increase the resorption, to prep. derivs. similar in structure to substances normally present in the body. The Na salts of mono- and dichaulmoogroyl-β-glycerophosphoric acids have been found to have distinct chemotherapeutic effects (cf. Kudicke, *Med. Welt*, in press). It was hoped that the therapeutic action of these compds. might be still further increased by converting them into choline esters analogous to the natural lecithins. *Choline esters of hydnocarpoyl-* (I) and *chaulmoogroylhydnocarpoyl-β-glycerophosphic acids* (II) were prepd. from the corresponding Ag salts and $BrCH_2CH_2NMe_3Br$; in m. p. and solubilities they greatly resemble natural lecithins but the hope that they might show increased therapeutic activity in rat leprosy has not been fulfilled. I, viscous yellowish mass with a faint amine-like odor, m. 160–5°, dissolves clear in water; the soln. (pH 4) is unchanged by neutralization with 2 *N* Na_2CO_3 but *N* HCl produces a faint turbidity and on heating hydnocarpic acid seps. II, microcryst. spherical aggregates from dry acetone, softens 70°, m. 170–5°. C. A. R.

The amino derivatives of pentaerythritol. II. Tetraaminotetramethylmethane. F. Govaert and M. Beyaert. *Proc. Acad. Sci. Amsterdam* **42**, 637–40(1939); cf. *C. A.* **28**, 4038[1].—The tetra-HBr salt (I) of the amine (II) obtained as previously described was added in alc. to satd. aq. KOH. The filtered soln. was again treated with KOH and the ppt. filtered. On concn. and cooling, the soln. sepd. into 2 layers. The lower layer being solidified KOH, the supernatant alc. soln. was decanted and the alc. distd. off. Finally $C(CH_2NH_2)_4.H_2O$, white, $b_{0.7}$ 108°, m. 41–2°, was sepd. from the residual KOH by distn. I refluxed with NaOAc and Ac_2O for 6 hrs. gave $C(CH_2NHAc)_4$, b_3 72.5–3°, m. 60°. $C(CH_2NHCONH_2)_4$, m. 230° (decompn.), was prepd. by dissolving I in freshly prepd. aq. AgCNO. H_2CO_3 salt of II, $C(CH_2NH_2)_4.2H_2CO_3$, m. 125° with loss of CO_2. The addn. of $HgCl_2$ soln. to II gave a white ppt. insol. in alc., slightly sol. in H_2O, $C(CH_2NH_2)_4.2HgCl_2$. III. **Dihydroxydiaminotetramethylmethane.** *Ibid.* 641–8.—The prepn. of the diamine was attempted in 2 ways: (1) Treatment of dibromopentaerythritol with alc. NH_3 followed by acetylation gave *3,3-bis(acctaminomethyl)oxacyclobutane*, $CH_2.O.CH_2.C(CH_2NHAc)_2$, in a low yield. With liquid NH_3 is reacted readily when the temp. was raised to 100°, but no definite product could be sepd. from the mixt. (2) The dihydroxydiaminotetramethylmethane $(HOCH_2)_2C(CH_2NH_2)_2.H_2O$, $b_{0.002}$ 200°, was finally prepd. by the action of aq. NH_3 satd. at 0° on dioxaspiroheptane, $CH_2.O.CH_2.C.CH_2.O.CH_2$, at 100° for 12 hrs. Yield, 78%. The diamine was further characterized as the dioxalate, m. 168° (decompn.), dipicrate, m. 223° (decompn.), and monocarbonate, which reverts to the pure diamine at 164°. Mark Plunguian

Chemistry of naturally occurring monoanhydrohexitols. II. Synthetic tetramethylstyracitol. Werner Freudenberg and John T. Sheehan. *J. Am. Chem. Soc.* **62**, 558–60 (1940); cf. *C. A.* **31**, 7846[1].—Zervas (*C. A.* **24**, 5027) has synthesized styracitol (I) but his method did not permit a decision as to whether it was a sorbitol or mannitol deriv. Oxidation rates with $Pb(OAc)_4$ (part I) favored the mannitol structure for I and the sorbitol structure for polygalitol (II). The following synthesis shows that I has the configuration of 1,5-anhydro-*d*-sorbitol as announced by Z. I yields a *tetra-Me deriv.* (III), $b_{1.5}$ 110° (all b. ps. for bath temp.), $[\alpha]_D^{25}$ −36.5° (no solvent unless indicated), n^{25} 1.4520, d. 1.0849. Tetramethylglucose (30 g.) in 75 cc. H_2O and 15 cc. EtOH, reduced for 7 hrs. at 135° and 1300 lb. H pressure in the presence of Raney Ni, gives *tetramethylsorbitol* (IV), b_2 145°, $[\alpha]_D^{25}$ 10.3° (EtOH, *c* 6.3), 4.7° ($CHCl_3$, *c* 10.5), n^{20} 1.4612; heating 15 g. IV and 2 cc. of 13% H_2SO_4 *in vacuo* for 0.5 hrs. at 140° gives *tetramethyl-1,5-anhydrosorbitol*, identical with III. That VI is not formed in the reduction is shown by the further methylation of IV to *hexamethylsorbitol*, $b_{1.5}$ 100°, $[\alpha]_D^{25}$ 1.97°, n^{22} 1.4367, d. 1.0334, which was also prepd. by direct methylation of sorbitol. II yields a *tetra-Me deriv.* (V), b_3 80°, $[\alpha]_D^{25}$ 67.67°, n^{22} 1.4444, d. 1.0571. Reduction of tetramethylmannose as above gives *tetramethylmannitol* (VI), b_3 150°, $[\alpha]_D^{25}$ 20.7° (EtOH, *c* 10.15), 17.5° ($CHCl_3$, *c* 10.6), n^{24} 1.4605; dehydration with 13% H_2SO_4 gives *tetramethyl-1,5-anhydromannitol* (VII), b_3 95°, $[\alpha]_D^{25}$

30.6°, n^{25} 1.4479, d. 1.0435; thus, **VII** is not identical with V, and I and II are not epimeric. *Hexamethylmannitol*, b_2 95°, $[\alpha]_D^{25}$ 12.53°, n_D^{25} 1.4403, d. 1.0458, was prepd. from VI or from mannitol. C. J. West

Benzoylation of *d*-sorbitol and *meso*-erythritol. S. Hanai. *Bull. Inst. Phys. Chem. Research* (Tokyo) **17**, 1224–35(1938).—Examn. of the decompn. products of partly benzoylated *d*-sorbitol and *meso*-erythritol shows that primary OH is more easily substituted than secondary. B. C. P. A.

Composition of lactic acid. Production of a highly concentrated acid. Paul D. Watson. *Ind. Eng. Chem.* **32**, 399–401(1940).—Lactic acid solns. can be concd. by distn. with liquids that form low-boiling binary mixts. with water. The anhyd. acid forms an equil. mixt. of 25% of the free acid and 80% of lactyllactic acid (expressed as free acid). Amy LeVesconte

1,2-Disulfide dicarboxylic acids, the corresponding disulfones and their decomposition products. Jan A. Reuterskiold. *Uppsala (Appelborgs Boktryckeriaktiebolag)* **1939**, 272 pp. (Separate.)—*Ethylenebisthioglycolic acid* (I), m. 107–8° (from PhMe), was prepd. by refluxing 1 mol. $CH_2(SH)CO_2H$ (in 95 cc. alc. and 100 cc. H_2O and neutralized with 2.2 mols. NaOH in 150 cc. H_2O) on the water bath with 0.5 mol. $C_2H_4Br_2$, and acidifying. *Ethylenebisthiolactic acid* (II), prepd. in 80% yield either from inactive $MeCHBrCO_2H$ (10% excess) and $C_2H_4(SH)_2$ in alk. soln. or from inactive $MeCH(SH)CO_2H$ and $C_2H_4Br_2$ in alk. soln., is 3 parts *dl*-acid and 5 parts *meso*-acid but the product of the 2nd method is more easily purified. Resolution of *dl*-**II**, m. 88.5–90° (sepd. from the H_2O filtrate from meso-II by addn of HCl at 0° and recrystn. from CCl_4 or C_6H_6), by means of the brucine salt was extremely difficult. Small amts., $[\alpha]_D$ 131° and −135°, were obtained in one case, but $[\alpha]_D$ 115° was obtained in another. The difficulties are ascribed to mixed crystals. *meso*-**II**, m. 116–18° (from $CHCl_3$), is less sol. than *dl*-II and gives cryst. mono-K, guanidine and *d*-$MeCHPhNH_2$ salts. *Ethylenebis-α-mercaptoisobutyric acid* (III), m. 167–8°, could be prepd. only from α-mercaptoisobutyric acid and $C_2H_4Br_2$ (85% yield). It gives a Cu salt. The mixt. of *dl*- and *meso*-*ethylenebismercaptophenylacetic acid* (IV), prepd. from inactive $PhCHClCO_2H$ and $C_2H_4(SH)_2$ in alk. soln. at 0° can be sepd. by fractional pptn. from AcOH by H_2O. *dl*-**IV**, m. 125–8°, satd. H_2O soln. 0.001 *N* at room temp., gives cryst. brucine, strychnine, quinine and $MeCHPhNH_2$ salts but could be resolved only by using the brucine or strychnine salts, giving an acid, $[\alpha]_D$ 66°. *meso*-**IV**, m. 155–8°, satd. H_2O soln. 0.0006 *N* at room temp., forms a neutral *d*-$MeCHPhNH_2$ salt. *Propylenebisthioglycolic acid* (V), m. 32–5° (from $MeCH(SH)CH_2SH$ and $ClCH_2CO_2H$, purified through the Cu salt (*C. A.* **25**, 1487)), with SO_2Cl_2 gives the *chloride* which with $PhNH_2$ in $CHCl_3$ gives the *dianilide*, m. 155-7°. The K, Na, Ca, and Ba salts are amorphous, the Cu salt decomp. on long heating in H_2O; the Ag salt (pptd. from the neutral H_2O soln. with $AgNO_3$) dissolves in a H_2O soln. of V to form the silver acid. V can be partially resolved (highest $[\alpha]_D$ 15.5°) through the brucine, strychnine or $MeCHPhNH_2$ salts. *Hydroxyethylthioglycolic acid* (VI) was prepd. from 94 g. $CH_2(SH)CO_2H$ by neutralizing with 120 g. soda crystals in 80 cc. H_2O, treating with $BrCH_2CH_2OH$ and ⅓ of a NaOH soln. (40 g. in 65 cc. H_2O) with cooling. The reaction was followed by titrating the unused $CH_2(SH)CO_2H$ with I in Na_2CO_3 soln., more NaOH added and if necessary more $BrCH_2CH_2OH$ to use up the acid as completely as possible. **VI** is purified by pptg. the Cu salt, treating with H_2S and H_2SO_4, filtering, adding $MgSO_4$, evapg., extg. with ether and drying with $NaSO_4$. On drying in air or with $CaCl_2$, or leaving the H_2O soln. 24 hrs., VI forms the *lactone*, m. 45–50° (from AcOH), which is not sol. in hot NaOH or acid solns. possibly because it is polymerized. VI forms a dark blue Cu salt; warmed with Ag_2CO_3 it gives a bright yellow *Ag salt*, with AcOEt in the presence of HCl or AcOH it forms $AcOCH_2CH_2SCH_2CO_2Et$ (**VII**), b_8 134.5–6.0°, which gives the complex $PtCl_4.2VII$, m. 100–1°. Attempts to oxidize VI with BzO_2H, H_2O_2 and $KMnO_4$ were unsuccessful. The 1,2-disulfide dicarboxylic acids, neutralized by NaOH, were oxidized by 5% $KMnO_4$ at 0° in an atm. of CO_2 or in the presence of $MgSO_4$ or H_2PO_4 or AcOH to give the corresponding 1,2-disulfonyl dicarboxylic acids whose equiv. wts. were detd. by titration with alkali at 0° and the SO_2 and CO_2 split off detd. by heating in a special absorption app. (*C. A.* **25**, 277). *Ethylenebissulfonylacetic acid* (**VIII**), m. 228–30° (Tiberg, *C. A.* **11**, 949), was sepd. from the acid K salt by heating with HCl and was recrystd. from HCO_2H and H_2O. *Ethylenebissulfonyl-α-propionic acids* (**IX**): the *dl-acid* m. 151–4° (from AcOH by addn. of petr. ether); the *active acid*, $[\alpha]_D$ −15°, is 80% racemized in soln. in 24 hrs.; the *meso*-form (recrystd. from AcOH by addn. of petr. ether), m. 183–6° without decompn., solidifies and then m. const. 150–60°, probably because some *dl*-acid is formed. *meso*-II (2.9 g.) in 150 cc. $CHCl_3$, oxidized at 15° with 81.5 cc. 1.21 *N* BzO_2H in Et_2O, and allowed to stand 3 days, distd. *in vacuo*, and the residue recrystd. from AcOH and petr. ether gives 40% of pure *meso*-**IX** but the method has no advantage over the $KMnO_4$ method. *Ethylenebissulfonyl-α-isobutyric acid* (**X**), recrystd. from AcOH and H_2O, m. 234–6° (decompn.). *Ethylenebissulfonyl-α-phenylacetic acids* (**XI**): the *dl-acid* decomp., giving off CO_2 so readily on heating in soln. that it could not be obtained pure. The *meso*-form, m. 220° (decompn.), gives a Ba salt. On heating with excess alkali **XI** decomp., giving a ppt. of vinyl benzyl sulfone. After extg. the concd. filtrates with ether and acidifying, $PhCH_2CO_2H$, m. 76–8.5°, ppts. *Propylenebissulfonylacetic acid*, m. 185–6°, was prepd. by the oxidation of V with solid $KMnO_4$. The 1,2-disulfone dicarboxylic acids are decompd. by adding 3.2 equivs. alkali slowly, giving sulfinic carboxylic acids which are sepd. by removing SO_4, SO_3, and CO_3 ions as Ba salts, neutralizing the solns., adding 1 mol. $SrCl_2.6H_2O$, heating to 35–40° and pptg. the Sr salts by the gradual addn. of Me_2CO (yield 90%). The sulfinic acids decomp. by heating with H_2SO_4 into the corresponding fatty acids, SO_2 and a small amt. of CO_2. The reaction velocity of the decompn. of Sr sulfinoacetate (from VIII and XII) is proportional to the H-ion concn. *Sr sulfino-α-propionate* ($3H_2O$) (from **IX**) is oxidized by H_2O_2 to sulfo-α-propionic acid. **X** gives *Sr sulfino-α-isobutyrate*. *1-Hydroxyethylsulfonylacetic acid* formed by the oxidation of VIII is sepd. from the mother liquor after the pptn. of the sulfino acid as Sr salt, by pptn. as a Pb salt (*C. A.* **25**, 277). The free acid, m. 87–9°, is obtained after the pptn. of PbS. **XII**, decompd. with NaOH, the soln. freed from sulfinic acid, SO_3 and Sr and dried, gives *Na 2-propene-3-sulfonylacetate* (**XIII**) which is freed from NaCl by extn. with MeOH. Bromination of XIII gives $Br_3CSO_2CBr_3$, m. 131–2.5°, and AcOH. The dissocn. consts. of the sulfide and sulfonyl acids were detd. with a quinhydrone electrode, the sulfino acids with a glass electrode. The calcd. distances between the charges on the carboxyl groups of the sulfide and sulfonyl acids agree with those calcd. for a plane mol. model and the sequence of the dissocn. consts. conforms to Ingold's + *I* effect of the alkyl. Thermodynamic dissocn. consts. are calcd. from the titration curve of a dil. soln. The decompn. of the 1,2-disulfone dicarboxylic acids in alk. soln. was studied alkalimetrically and by a special potentiometric method for low OH-ion concn. The bimol. reaction const. increases with decreasing OH-ion concn. The reaction is bimol. for concns. between 10^{-3} and 10^{-5}. The methods (*C. A.* **27**, 5727[1]) and theory of the methods are described in detail. Deviations from the course of a bimol. reaction are ascribed to the presence of various configurations of the acids with limited rotation and, because of the potentials in the reaction centers, dissimilar reaction velocities. The 1,2-disulfone dicarboxylic acids decomp. in acid soln. at 100°, giving off CO_2 and a small amt. of SO_2. The velocity of this reaction decreases with increasing H-ion concn. The mechanism of the alk. decompn. is discussed. 231 references. Janet E. Austin

Glycidic acid amides with hypnotic properties. Study of the Claisen-Darzens reaction. Ernest Fourneau and J. R. Billeter. *Bull. soc. chim.* **6**, 1616–25(1939).—It is considered that, for want of a better explanation, the glycidic

esters are formed by the condensation of $ClCH_2CO_2Et$ with the enolates of ketones and aldehydes when enolization is possible and with an assocn. product when enolization cannot take place. Glycidic esters have been prepd. by using NaOEt, $NaNH_2$ and Na, the last being preferable since it avoids the prepn. of NaOEt. A mixt. of 50 g. of MeCO-C_6H_{13} (m. 128°) and 48 g. $ClCH_2CO_2Et$ in an equal vol. of ether was added dropwise to 9 g. Na in ether. The cooled reaction mixt. was kept overnight and boiled for 2–3 hrs The product was poured into H_2O and the dried ether layer was evapd. down and distd., yielding 41% of Et β-hexyl-β-methylglycidate, $b_{0.9}$ 118–22°. A mixt. of 10 g. of methylpropylglycidic esters (I) and 5 mol. of 20% $MeNH_2$ in aq. alc. was heated 4 days at 80°, 18 hrs. at 100° and 18 hrs. at 140°. The reaction mixt. was acidified with HCl, extd. with ether and made alk. with NaOH and dry Na_2CO_3. The thick mass was extd. with ether, yielding 4 g. of MePrC(OH)CH(NHMe)CONHMe, m. 119°; HCl salt, m. 198°. Similarly, heating a mixt. of 20 g. I, 60 g. of 33% $NHMe_2$ in benzene, 10 cc. MeOH and 2 cc. H_2O for 18 hrs. at 150° gave 1.2 g. of *EtCH:CMeCH₂NMe₂*, b_{30} 76°; *MeI deriv.*, m. above 300°. The passage of 4 g. of dry HBr through 3 g. of diethylglycidamide in 60 cc. of anhyd. ether gave 3.8 g. of a product quite different from the expected bromohydrin. The tetra-substituted amides have very distinct hypnotic properties. C. R. Addinall

Isolation of a crystalline derivative of pantothenic acid. D. W. Woolley. *Science* **91**, 245-6(1940).—The Na salt of concentrates of the lactone of the acid fragment of pantothenic acid was acetylated The Ac acid was converted into the acid chloride by means of $SOCl_2$ and the chloride was poured into concd. NH_4OH. The alc.-sol. fraction of the reaction product was slowly crystd. from a small vol. of alc. and Me_2CO as long needles. After hydrolysis by means of NaOH the crystals were active when tested by the use of hemolytic streptococcus. Recrystn. from an alc.-ether mixt. or an EtOAc-Me_2CO mixt. or sublimation in a high vacuum did not alter the activity. A few mg. of the crystals was hydrolyzed and the HO acid recombined with β-alanine. The resulting product was highly active in promoting growth of *Lactobacillus casei* or rats fed a synthetic ration. Felix Saunders

Structure of pantothenic acid. Roger J. Williams and Randolph T. Major. *Science* **91**, 246(1940).—From concentrates contg. 3–40% Ba pantothenate a cryst. lactone, $C_6H_{10}O_3$, m. 91–2°, was isolated after degradation of the pantothenate. The lactone was shown to be α-hydroxy-β,β-dimethyl-γ-butyrolactone (I). Synthetic I was condensed with β-alanine to give physiologically active pantothenic acid. Felix Saunders

Reduction over a Raney catalyst of the esters of α-amino acids to corresponding alkamines. G. Ovakimian, Martin Kuna and P. A. Levene. *J. Am. Chem. Soc.* **62**, 676–7(1940).—A note stating that reductions of the esters of leucine (*dl* and *l*) and phenylaminoacetic acid (*dl* and *l*) have been carried out with Raney Ni at 150 atm. pressure and temps. of 135°, 70°, 40° and 40°, resp. The yields vary from 40 to 60%. C. J. West

Multivalent amino acids and peptides. XI. Synthesis of diglycyl-*l*-cystine. J. P. Greenstein. *J. Biol. Chem.* **128**, 241–3(1939); cf. *C. A.* **32**, 7489⁴.—Treatment of carbobenzyloxyglycine with PCl_5 in ether, followed by *l*-cystine in aq. KOH, and reduction (Na in liquid NH_3) of the product yield cryst. diglycyl-*l*-cystine ($+1H_2O$) (Fischer and Suzuki, *Ber.* **37**, 4575(1904)), m. 232°, $[\alpha]_D^{25}$ −108° in *N* HCl, rapidly hydrolyzed by intestinal erepsin (the *l*-cystine produced being fully active), but not by carboxypeptidase. B. C. P. A.

Hydroxylysine. D. D. Van Slyke, Alma Hiller, Douglas A. MacFadyen, A. Baird Hastings and Friederich W. Klemperer. *J. Biol. Chem.* **133**, 287–8(1940); cf. *Proc. Soc. Expt. Biol. Med.* **38**, 548(1938).—Evidence is presented which indicates that the diamino acid crystd. from gelatin in all probability has one of the 2 following structures: $NH_2CH_2CH(OH)(CH_2)_2CH(NH_2)CO_2H$ or $CH_2(OH)CH(NH_2)(CH_2)_2CH(NH_2)CO_2H$. A. P. L.

Synthesis and determination of the lipotropic activity of the betaine hydrochlorides of *dl*-serine, *dl*-threonine and *dl*-allothreonine. Herbert E. Carter and Donald B. Melville. *J. Biol. Chem.* **133**, 109–16(1940).—Methylation of *dl*-serine, *dl*-threonine and *dl*-allothreonine was accomplished by use of Me_2SO_4 under carefully controlled conditions. The hydroxy betaine HCl salts do not prevent the development of a fatty liver in rats fed a high-fat, low-protein diet, thus differing from choline and betaine. The betaines of *dl*-threonine and *dl*-allothreonine undergo a retrograde aldol condensation in alk. soln., giving betaine and AcH. *dl-Serine betaine-HCl* m. 198–9°. *dl-Threonine betaine-HCl* m. 162–4°. *dl-Allothreonine betaine-HCl* m. 166–8°. A. P. Lothrop

Preparation of galacturonic and mucic acids from pectic substances. Hugh H. Mottern. *Research Studies, State College Washington* **7**, 153–4(1939); cf. *C. A.* **34**, 379⁶.—This is an abstract without data of a thesis at Wash. State College (Document 1291, Bibliofilm Service, U. S. Dept. Agr. Library, Wash., D. C.). The nomenclature of pectic substances is discussed. Two new addns. are suggested, namely *polygalacturonic acid* and *pectinic acid*. Pectin is essentially a linear, high-mol.-wt. polymer of galacturonic acid with the carboxyl groups more or less esterified with MeOH, and with the arabinose and galactose occurring in a side chain if attached to the polymer. Methods for the prepn. of polygalacturonic acid, a polymer consisting only of galacturonic acid units, and for its enzymic hydrolysis to α-*d*-galacturonic acid are described. The enzymic hydrolysis of com. available polygalacturonic acid by pectinase enzyme prepns. gave a simple, satisfactory method for prepg. galacturonic acid. Galacturonic acid yielded mucic acid on oxidation with HNO_3. C. R. Fellers

Isolation of keturonic acids. II. L. T. Crews, J. P. Hart and M. R. Everett. *J. Am. Chem. Soc.* **62**, 491–3(1940); cf. *C. A.* **33**, 6801¹.—Oxidation of 1% carbohydrate solns., prepn. of the mixed Ba salts and isolation of the cryst. brucine salts were conducted according to the methods of part I. Yields of mixed Ba salts from 4-g. quantities of the carbohydrates were: *l*-xylose 4.1 g.; *l*-arabinose 3 g., *d*-glucosamine-HCl 1.7 g. *Brucine l-xyloketuronate* (I), with 1 mol. H_2O, results in 2.5-g. yield from 3.75 g. Ba salts; recrystd. from H_2O, it m. 147–8° (decompn.), $[\alpha]_D^{25}$ −29.5° (1% aq. soln.). *Brucine l-araboketuronate*, with 2 mols. H_2O, m. 160–1°, $[\alpha]_D^{25}$ −13° (1% aq. soln.), results in 0.78-g. yield from 2.9 g. Ba salts; this closely resembles the *d*-isomer of I but complete identity has not been proven. *Brucine d-chuloketuronate*, with 1.5 mols. H_2O, m. 177–8°, $[\alpha]_D^{25}$ −50.5° (1% aq. soln.), results in 0.52-g. yield from 1.95 g. of the mixed Ba salts from *d*-glucosamine. During concn. of the Ba salt soln. prepd. from oxidized levoglucosan (II) there sepd. *ketolevoglucosan* (0.65 g. from 4 g. II), $C_6H_8O_5.0.5H_2O$, m. 181–2° (decompn.), $[\alpha]_D^{25}$ −62° (1% aq. soln.); a 1% soln. in H_2O is obtained only by warming; it reduces Sumner reagent at room temp.; hydrolysis with 6 *N* H_2SO_4 for 2.5 hrs. on a boiling water bath decreases the rotation from −62 to −34° and causes a 33% reduction in reducing power; there is probably a hydrolysis of the anhydride linkage; subsequent oxidation of the hydrolyzate with Br for 48 hrs. at 25° causes a 50% loss of reduction, which indicates the appearance of an aldose radical during hydrolysis. The original reducing substance was not affected by similar Br oxidation. This compd. is an anhydride of a dicarbonyl sugar. Suggestions are made for naming dicarbonyl sugars. The anhydro derivs. are probably unimol. C. J. West

Preparation of ethyl tetramethylenedicarboxylate by the Kizhner method. B. A. Kazanskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 1568(1939).—A polemic with Venus-Danilova, *C. A.* **32**, 7897⁵. Chas. Blanc

Ethyl hydrogen methyldiglycolates. Pierre Vièles and Mohammed Amir. *Compt. rend.* **209**, 457–9(1939).—V. and A. prepd. the *dl*-forms by 2 different methods: the action of EtOH on the anhydride of *dl*-methyldiglycolic acid (*C. A.* **1**, 2683) and half-sapon. of di-Et *dl*-methyldiglycolate. In both methods viscous liquids were obtained, sol. in H_2O (alkali and alk. earth salts as well), sol. in Et_2O, EtOH, and C_6H_6. The phys. consts. appear the

same because of exptl. errors: b_{30} 168–70°, d^{25}_4 1.148, n^{25}_D 1.4331, mol. refraction 38.8 (calcd. 39.4). Nevertheless these 2 products are not identical for it can be shown that the monoester prepd. by half-sapon. saponifies more rapidly than that obtained from the anhydride; thus at 75° with 10 times the theoretical quantity of *N*/80 alc. HCl, the velocity consts. are in the ratio of 1.6:1. In order to establish the structure of the active forms of the mono-Et methyldiglycolates, esterification with MeOH was employed. In the case of mixed active isomers the ratio is established from the observed rotatory power and the known rotatory power of pure active forms previously detd. (*C. A.* **30**, 4818[3]). W. A. Cook

Derivatives of calcium cyanamide. V. Formation of guanidine from dicyanodiamide. 1. Formation of guanidine from dicyanodiamide by electrolytic reduction. Kiitiro Sugiao. *J. Chem. Soc. Japan* **60**, 111–21(1939); cf. *C. A.* **34**, 2273[3]; *J. Electrochem. Assoc. Japan* **6**, 292 (1938). —The structures assigned to dicyanodiamide (I) by Bamberger (*Ber.* **26**, 1584–5(1893)) and by Bell (*C. A.* **21**, 2444) do not correspond to all the reactions of the compd. Cathodic reduction of 1% I in 1% H_2SO_4 with a Hg or Pb cathode and c. d. of 1 amp. per sq. dm. gave $C_2H_8N_4$ (II), stable in acid soln., but undergoing hydrolysis and reduction as the soln. becomes alk. by further electrolysis. II is hydrolyzed according to: $C_2H_8N_4 + H_2O = NH_2C(:NH)NH_2 + NH_3 + HCHO$. A small amt. of $MeNH_2$ found with NH_3 indicates also the reaction: $C_2H_8N_4 + 2H = NH_2C(:NH)NH_2 + MeNH_2$. That neither HCN nor guanylurea was detected in the product disproves Bell's theory. However, guanylurea is produced at the early stage when I is electrolytically reduced in 20% H_2SO_4. These results indicate the presence of both a guanidine group and an isonitrile group. The reactions at high temp. of I with amine salt and with phosphoric acid indicate the presence of —C:N; reactions in dil. aq. soln. indicate the presence of —N:C. These facts are explained by the structures in equil.: $NH_2C(:NH)NHCN \rightleftarrows NH_2C(:NH)NHNC$. For electrolytic reduction of I, metals having high overvoltage give the best yield e. g., at c. d. 1 amp. per sq. dm. with Hg 31%, with Pb 49%, with Zn 6%, with Zn amalgam 15% yields; Cu and Ni give no II. High c. d. gives better yield. I is not reduced in neutral or alk. soln. K. Shinohara

Some ninhydrylureas and alloxanylureas and their constitution. Michel Polonovski, Pierre Gonnard and Genevieve Glotz. *Bull. soc. chim.* **6**, 1557–76(1939).—The real state of urea (I) in soln. may be an equil. mixt. of the amphoteric $OC(NH_2)NH_2$ form and the tautomeric isourea, $HOC(NH_2):NH$, in different proportions according to the nature of the solvent, in particular with respect to its polarity. Chem. and spectrographic studies of compds. of I and several substituted ureas with xanthydrol (II), triketohydrindene hydrate (III) and alloxan (IV) show that in many cases, the 2 N functions of I do not react symmetrically and that, according to the polarity of the solvent, a different equil. of the 2 tautomeric forms is established. Tests were made with $MeNHCONH_2$ (V), Me_2NCONH_2 (VI), $CO(NHMe)_2$ (VII), $PhNHCONH_2$ (VIII) and $CO(NHPh)_2$ (X). II reacts symmetrically with I, monoxanthyl compds. are formed with V and VI, but no compd. is formed with VII. Although the activities of the 2 NH_2 groups may differ the affinity of each for II in acid media is sufficiently strong to prevent the detection of the monoxanthyl intermediate. II replaces I and its asym.-substituted compds. from the majority of their other combinations. Mixts. of 0.004 mol. III in 10 cc. of hot H_2O and 0.004 mol. of substituted urea in 1–2 cc. H_2O were heated for 30 min. at 100°, concd. and recrystd. from hot H_2O, yielding *ninhydrylmethylurea*, $C_{11}H_{10}N_2O_4$, m. 230°; *ninhydryl-asym-dimethylurea*, $C_{12}H_{12}N_2O_4$, m. 260° (decompn.), and *ninhydrylphenylurea*, $C_{16}H_{12}N_2O_4$, m. 105° (decompn.). No combination was possible with sym.-disubstituted ureas. Thus an NH_2 group must be free and it is probable that I reacts in the tautomeric form. Mixts. of aq. solns. of IV and of I, V and VII gave alloxanylureas. By the addn. of a trace of Br, IV was condensed with VI to give *alloxanyl-asym-dimethylurea*, $C_7H_{10}N_4O_5$, m. 180–1° (decompn.). A mixt. of 1 g. VIII in a min. of H_2O at 80° and 4 g. IV in a min. of hot H_2O was heated at 80–90° for 40 min. The cooled soln. gave *alloxanylphenylurea*, $C_{11}H_{10}N_4O_5$, m. 180–5° (decompn.). No oximes or semicarbazones could be prepd. and it seems that the ureas combine through 1 NH_2 group with the C atom in the 5-position of the alloxan. Since the chem. study failed to give any convincing evidence as to the existence of an imidazole ring in most of the compds. a spectrographic study was made of solns. at various pH values of urea compds. with III, IV and of the following barbiturates; nitrobarbituric acid, pseudouric acid, uramil, cyanacetylurea, aminodihydroxypyrimidine and aminouramil. The spectra obtained with III indicated a more or less ionized mol. in alc. soln. but gave no further information as to the intimate structure of the compds. Below pH 7, the compds. with IV showed an equivalence of the 2 NH_2 groups and the possibility of a cyclic structure whereas, in solns. above pH 7, the compds. seemed to be present in an equil. mixt. of the various possible forms. The absorption spectra of the barbiturates showed that all the compds. exist in equil. between the various tautomeric forms in proportions which are functions of the polarity of the solvent. Adsorption curves are presented in 10 plates and show several new spectra of the barbiturates. C. R. Addinall

Diliturates (5-nitrobarbiturates) of some physiologically important bases. C. E. Redemann and Carl Niemann. *J. Am. Chem. Soc.* **62**, 590–3(1940).—Dilituric acid (I) surpasses picric acid, styphnic acid, picrolonic acid, nitroanilic acid and 3-nitrodiketohydrindene as a reagent for the isolation of many naturally occurring bases. The soly. of I (in millimoles per l.) at 25° is: MeOH 99, 95% EtOH 85, H_2O 63, abs. EtOH 35, Me_2CO 25, Et_2O 0.9, C_6H_6 0.4. I behaves like a strong monobasic acid, the acid strength being between picric acid and HCl. I is a satisfactory reagent for the sepn. of K from binary mixts. contg. Na and is an excellent reagent for the isolation of Mg. Soly. of inorg. salts of I in H_2O at 25°: Mg 0.1, Ba 1.3, Sr 1.7, Cu 4.8, K 3.9, Ca 5.7, Ag 12, Na 38. Soly. of org. salts of I in H_2O at 25°: $C_2H_4(NH_2)_2$ 0.6, NH_3 7.3, $EtNH_2$ 13, Me_2NH 15, Ph(iso-Pr)NH 15, $BuNH_2$ 17, $AmNH_2$ 24, $PhNH_2$ 26, $MeNH_2$ 37, Bu_3N 51, quinoline 23, imidazole 36, C_5H_5N 54, d(+)-glucobenzimidazole 65, morpholine 80, *dl*-ephedrine 8.7, β-$HOC_6H_4CH_2CH_2NH_2$ 13, *l*-ephedrine 30, *d*-pseudoephedrine 32, *l*-adrenaline 37, $HOCH_2CH_2NH_2$ 53, *d*-glucosamine 85, $(HOCH_2CH_2)_3N$ 132, $H_2NCH_2CH(OH)Me$ 134, quinine 1.6, brucine 3.7, strychnine 3.9, cinchonine 9.0, nicotine 12.3, caffeine 68, *l*-diiodotyrosine 2.2, *dl*- and *l*-lysine 6.4 and 9.0, *l*-histidine 7.9, *l*-tyrosine 10.0, *l*-arginine 10.2, *l*-cystine 15, *dl*-phenylalanine 16, *dl*-α-aminoisobutyric acid 20, *l*-tryptophan 20, *dl*-aminophenylacetic acid 28, sarcosine 34, betaine 34, *dl*-α-aminobutyric acid 40, *l*- and *dl*-alanine 43 and 50, glycine 49, *dl*- and *l*-aspartic acid 61 and 94, *l*- and *dl*-glutamic acid 67 and 90, *dl*-γ-aminobutyric acid 77, *l*-cysteine 92, *dl*- and *l*-leucine 94 and 105, *l*-proline 100, *l*-asparagine 103, *dl*-valine 107, *dl*-isoleucine 107, *dl*-norleucine 109, *dl*-norvaline 110, *dl*-methionine 112, *dl*-serine 112, *l*-hydroxyproline 141, guanidine 7.0, tyramine 8.7, histamine 17, phenylethylamine 19, creatinine 23, urea 36. Regeneration of bases from their diliturates can be achieved in the majority of cases by simply replacing the base in question by either $C_2H_4(NH_2)_2$, Mg or NH_4; the glycine salt with NH_3 gives 89% of cryst. glycine. C. J. West

Hydrogenation of saccharides. II. K. Yosikawa and S. Hanai. *Bull. Inst. Phys. Chem. Research* (Tokyo) **17**, 1262–77(1938); cf. *C. A.* **29**, 5080[1].—Hydrogenation of glucose (70–120°) and of sucrose and starch (160–80°) at 80–300 atm. with Ni or Ni-Fe catalysts yields mixts. of hexitols. At 190–240°, propylene glycol and glycerol are formed in good yields, together with $(CH_2OH)_2$, EtOH, and MeOH. The mechanism of the hydrogenation is discussed. B. C. P. A.

Synthesis of 5,6-dimethylglucose. M. R. Salmon and Garfield Powell. *J. Am. Chem. Soc.* **61**, 3507–10(1939).—In the abstract in *C. A.* **34**, 992[4], the yield of 3-benzyloxymethylacetoneglucose (1.23 g.) is an error; the crude

yield is about 110% (private communication). In line 18 of this abstract delete the phrase: "this also results from II and PhNCO." The derivs. of dimethylglyceric acid mentioned in the last 2 lines are those of the *dl*-acid.
C. J. West

Oxidation of aldose by hypoiodite. VI. Glucosone (2-ketoglucose). Karl Myrbäck. *Svensk Kem. Tid.* 51, 225–9(1939); cf. *C. A.* 34, 9928.—Glucosone is less stable in alk. solns. than glucose but in sufficiently dild. NaOH and $NaHCO_3$ solns. the oxidation by hypoiodite is about the same. The conversion of HCOH to CO at the 2nd C atom has no effect on the oxidation velocity of the aldehyde group.
A. R. Rose

Nature of the carbohydrate residue in ovomucoid. I. The glucosamine constituent. M. Stacey and J. M. Woolley. *J. Chem. Soc.* 1940, 184–91.—Ovomucoid (I) is prepd. in 3% yield by tryptic digestion of com. egg albumen, $[\alpha]_D^{20}$ −44° (H_2O, *c* 1); Sevag's method (*C. A.* 29, 1122[5]) gives 4%, $[\alpha]_D^{20}$ −57° (H_2O, *c* 1); dried egg white gives 10% of a I with $[\alpha]_D^{20}$ −57° (H_2O, *c* 1); color reactions indicate the probable presence of tryptophan, tyrosine, arginine and histidine. The carbohydrate residue (II) is prepd. by a modification of the method of Fraenkel and Jellinek (*C. A.* 21, 3603) in 16% yield; it contains 5.5% N (Dumas) and 4.9% amino N and has 0° rotation; further hydrolysis with $Ba(OH)_2$ did not alter materially the N content of II. It was proved, in part at least, that H atoms of the NH_2 groups in the glucosamine residue in I are replaced by Ac groups and that in the prepn. of II the $Ba(OH)_2$ treatment causes considerable deacetylation; apart from this, the method of isolation did not materially alter the nature of the II. Hydrolysis of 4 g. II with 100 cc. 5 *N* H_2SO_4 at 100° for 36 hrs. gives glucosamine (isolated as the HCl salt), mannose (as the phenylhydrazone) and galactose (identified by mucic acid formation). II with Ac_2O and C_5H_5N, heated for a few min. at 70° and then vigorously shaken at 15° for 24 hrs., and the treatment repeated with the insol. portion until almost complete soln. is effected, gives the *Ac deriv.* as a light brown powder, $[\alpha]_D^{20}$ −20° (H_2O, *c* 2), 29% *O*-Ac; heating with 10% $Ba(OH)_2$ at 95° for 1 hr. gives the *N-Ac deriv.*, $[\alpha]_D$ 0° (H_2O, *c* 1.4), 11.5% *N*-Ac. Attempts to methylate I or II with Me_2SO_4 and NaOH result in almost complete destruction of the polysaccharide. MeI and Ag_2O or MeI in liquid NH_3 also fails to give satisfactory products. Me_2SO_4 and NaOH in CCl_4 give 10% of a Me deriv. with 23.8% of MeO. Finally a method was used (full details given) which avoids excess alky. in the initial stages of methylation; the acetate in H_2O and CCl_4 was treated with Me_2SO_4 and NaOH at 50° and the product of this reaction with MeI and Ag_2O, giving a *Me deriv.* (III) with 31.5% MeO, $[\alpha]_D^{20}$ 0° in H_2O or $CHCl_3$. Complete details are given of the hydrolysis of III with 2% MeOH-HCl for 48 hrs. and the sepn. of the components; the products include 10% of 2-acetamido-3,4,6-trimethyl-α-methylglucoside (IV) (Cutler, Haworth and Peat, *C. A.* 32, 1661[1]), 30% of a sirupy fraction of 3,4,6-trimethyl-α-methylglucosaminide (V), which yields IV on acetylation, 10% of a sirupy mixt. of partially methylated hexoses (methylation, hydrolysis and reaction with $PhNH_2$ gives a mixt. of tetramethylmannose and tetramethylgalactose anilides in the ratio of approx. 4:1) and 50% of a sirup which on methylation with Ag_2O and MeI gives a light brown powder which appears to be a compd. of AgI with glucosamine derivs. From the quantities of IV and V it is possible to state that at least 40% of III is built up of methylated glucosamine residues. The quantity of IV shows that at least 10% of these residues are "end-groups" joined by glucosidic links to the rest of the mol. and the yield of V indicates that at least a further 30% of the residues are joined by glucosidic links or through the NH_2 groups. Inasmuch as III has an Ac content of about 10% it appears likely that the major part of V is also linked glucosidically.
C. J. West

Polysaccharides. XXXIX. The constitution of certain levans formed by bacterial action. R. R. Lyne, S. Peat and M. Stacey. *J. Chem. Soc.* 1940, 237–41; cf. *C. A.* 34, 1624[4].—The polysaccharides produced from sucrose by *B. megaterium*, *Bact. pruni* and *Bact. prunicola* are polyfructoses of the levan type. From an examn. of the products of hydrolysis of the methylated levans it was demonstrated that each levan could be structurally represented by a terminated chain of 10–12 contiguous fructofuranose units mutually linked through positions 2 and 6 as in the levan formed by *B. subtilis;* thus, certain differences in properties between the levans were probably due to varying degrees of aggregation of the "repeating unit." Anomalies in the optical rotations of levan acetates have been shown to arise from incomplete acetylation of the levan. Details are given of the methylation and hydrolysis of the methylated product of each levan. The rotation of the acetates varied in a remarkable manner according to the proportion of H_2O present; within certain limits a decreased quantity of water present in the acetylation mixt. gives a product with an increased Ac content; the more highly acetylated products showed a higher pos. rotation than those which were incompletely acetylated; with 44.8% Ac $[\alpha]_D$ is 23° ($CHCl_3$); with 43.2% Ac, $[\alpha]_D$ is −13° ($CHCl_3$); each yielded the same levan on deacetylation.

Structure of γ-sugars. III. Preparation of 3,4,6-trimethylfructose. Frank Hartley and Wilfred H. Linnell. *Quart. J. Pharm. Pharmacol.* 12, 743–52(1939).—3,4,6-Trimethylfructose (I) has been prepd. by hydrolysis of methylated inulin and purified by conversion to the Me fructoside followed by hydrolysis. The position of the substituents in I has been established by the identity of its phenylosazone with that of 3,4,6-trimethylglucose. The synthesis of I has been effected by an unambiguous route. 24 references.
W. O. E.

Extraction of ethyl galactoside from yellow sweet lupines. F. E. Nottbohm and F. Mayer. *Vorratspflege u. Lebensmittelforsch.* 1, 243–7(1938); *Chem. Zentr.* 1938, II, 3402–3; cf. *C. A.* 31, 5719[8].—In the extn. of phosphatides from yellow sweet lupines it was found possible to isolate *α-Et galactoside*[2] (I). The lupines were ground and extd. with a 4:1 benzene-alc. mixt. in a Soxhlet app. for 3 hrs. After the liquid was evapd. to a sirup, I was obtained by crystn. from $CHCl_3$, then from alc. in fine platelets m. 143°, $[\alpha]_D$ 185° (water). Since I does not crystallize from the $CHCl_3$ soln., it can be obtained only after pptn. of the phosphatides with acetone from the evapd. mother liquor. It is thought that I occurs in the lupines as a lupine phosphatide-galactoside.

Labiose, a new trisaccharide of the trehalose type. S. M. Strepkov. *J. Gen. Chem.* (U. S. S. R.) 9, 1489–92 (1939).—A new trisaccharide (I), named *labiose*, was isolated from *Eremostachys labiosa*, fam. *labiata*, growing wild in the mountainous regions of Central Asia. I crystallizes with 3 mols. H_2O from the alc. ext. of the dry and crushed plant tubers, preliminarily washed with ether. It is a slightly sweet sugar, m. 126–8° to a glass-like mass and becomes brown at 205°. With anhyd. NaOAc and Ac_2O it gives a *hendecaacetate*, m. 88°, $[\alpha]_D^{20}$ 122.5° ($CHCl_3$). I has $[\alpha]_D^{20}$ 136.7°, does not reduce Fehling soln. and gives the Selivanov ketose reaction. It is completely hydrolyzed by invertase at 47–8° in 20 hrs. and by 1% HCl at 68–70° in 10–12 min. to 1 mol. of galactose and 2 mols. of fructose. Emulsin does not hydrolyze I. It follows that I is related to the α-series and, probably, has the galactose in the center position of the mol. Pressed yeast ferments I but little.

Enzymic degradation of polymeric carbohydrates. IV. Comparative enzymic degradation of some isolated wood constituents. Theodor Ploetz. *Ber.* 73B, 57–60(1940); cf. *C. A.* 34, 1169[8].—As reported in part III, native (linden) wood, contrary to the fraction obtained from $(CH_2NH_2)_2$-CuO soln., is very difficultly attacked by enzymes.[9] The work of Karrer, *et al.* (*C. A.* 20, 1416), on the snail enzyme, showing that native cellulose offers much greater resistance to enzymic attack than a cellulose which has undergone some repptn. process, raises the question whether or not this resistance of native cellulose may explain the difficulty with which wood is attacked. To test this point cellulose was isolated from woods by the Cl process and its behavior on enzymic degradation studied.

The skeletal substances obtained by the Schmidt ClO_2 process, which contain almost the whole of the carbohydrate complex of the wood, are of special interest in this connection, and samples of spruce- and beechwood skeletal substances furnished by S. were included in this investigation. The degree of degradation of the cellulose or skeletal substance by various purified snail enzyme prepns., measured by detg. the reducing sugar formed, was compared with the degradation, by the same prepn., of cuprophan (a reppd. cellulose), because the degradation of the woods themselves was too slow for comparison. The results showed that celluloses prepd. by the Cl process are degraded, depending on the activity of the enzyme, only very little more slowly than, or even as rapidly as, cuprophan. Beechwood skeletal substance is degraded about half as rapidly as the same wt. of cuprophan and spruce-wood skeletal substance is attacked even more rapidly. An interesting fact is that an enzyme prepn. free of cellulase but contg. an active lichenase did not attack beechwood skeletal substance in spite of the hemicellulose content of the latter. That the enzymic degradation of the complex polysaccharide mixt. which constitutes beechwood skeletal substance is selective was shown by the increase in C content of the undissolved residue as the degradation progressed. These expts. show that the increased resistance of the native cellulose or the total native carbohydrate complex which, with the lignin, makes up the wood substance does not suffice to explain the difficulty with which the wood is attacked by the snail ferment. If the behavior which these substances show when isolated conditioned the velocity of degradation the degradation of wood should be considerably more rapid. There remain 2 possible explanations of the behavior of wood: either the cellulose or the greater part of the carbohydrates is so protected, purely mechanically, by the lignin that the enzyme cannot gain access to it, or the polysaccharides are chemically combined with the lignin component and the enzyme cannot dissolve the union. **V. Enzymic degradation of some native lignin-containing materials.** *Ibid.* 61–73.— P. has for the first time been able to effect extensive degradation of native lignin-contg. materials with isolated enzymes. As shown in earlier papers, various samples of trunk wood, even when very finely ground, are very resistant toward the snail enzyme. The resistance is never absolute but the degradation comes to a stop when a few percent of the wood has gone into soln. Only when the wood has previously been subjected to chem. attack does this condition alter materially. It occured to P. to use, instead of the dead trunk wood, a lignified (i. e., lignin-contg.) but still living tissue. He chose as starting materials the pith of the elder tree and of the Australian *Araucaria excelsa*. The elder-tree pith was sepd. into the material obtained from the still green shoots of the current year's growth and that obtained from older parts of the tree. The difference in age was clearly manifested by the lignin content (the residue obtained by digestion with H_2SO_4 and subsequent treatment with dil. HCl according to the Klason method). Below are the values (%) found for 1 young and 3 old piths, resp.: ash 1.8, 0.8, 1.15, 2.97; pentoses 27.45, 33.9, 27.0, 22.6; lignin 14.07, 17.4, 18.5, 25.6; pure cellulose (crude cellulose corrected for pentose content) —, —, 35.61, 35.38. Compn. of original pith: C 48.21, 48.66, 49.14, 48.88; H 6.71, 6.43, 6.3, 6.15; MeO 4.82, 5.21, 5.03, 5.48. Compn. of lignin: C 65.18, 67.24, 66.17, 65.49; H 6.28, 6.46, 6.04, 5.74; MeO 18.80, 17.78, 19.66, 17.20. As shown by these values, only 54.9, 59.4, 72.3 and 80.3% of the total MeO of the 4 original piths, resp., are recovered as lignin, and since the original MeO contents differ but little it may be concluded that the increase in lignin formation with age is not accompanied by the formation of new MeO; the lignin would seem to be the result of a chem. transformation or merely condensation or polymerization of constituents of the young plant. The microscopic picture of the phloroglucinol-HCl reaction of sections of the elder-tree pith shows a uniform coloration, i. e., distribution of lignin through the tissue, whereas in the araucaria pith the tissue is practically lignin-free but permeated with strongly colored individual cells. In addn. to the pith, which offers the advantage that a quantitatively cleaner sepn. from the other parts of the wood can be effected, the extreme outside layer of the trunk, the cambial tissue and the bast also seem suitable for enzymic degradation expts. The following values were obtained for the pith, bast (extd. with benzene-alc.) and trunk wood (extd. with benzene-alc.), resp., of araucaria: pentoses 14.4, 14.0, 12.3; lignin 16.03, 17.25, 28.55; pure cellulose —, 37.8, 40.1. Compn. of original material: C 47.88, 52.73, —; H 6.29, 52.73, —; MeO 3.50, 3.97, —. Compn. of lignin: C 62.57, —, 68.32; H 5.15, —, 5.62; MeO 6.55, —, 15.32. As expected, araucaria pith and bast, unlike the resistant trunk wood, readily undergo enzymic degradation. The most important result of the expts. was that in the course of the degradation the C and MeO contents of the residue increase greatly, confirming the results with materials pretreated chemically (see part VI, below) and apparently proving that in wood substances of higher C content (lignins) are preformed. The real object of the work, the isolation of a pure lignin by enzymic means, was not attained because, even with these easily attacked materials, the degradation gives a product contg. both lignin and carbohydrate. Depending on the starting materials, there is more or less of a difference between the amts. of lignin (based on the Klason method of detn.) in the native tissue and in the residue of the degradation. A part of the substances in the original material which are detd. as lignin must therefore dissolve during the degradation. In fact, the degradation soln. contains MeO. But this is also the case where, as with young elder-tree pith, there is no disappearance of lignin during the degradation. The 2 solns. behave differently toward dil. H_2SO_4, however. Where lignin disappears during the degradation, the soln. on heating with 2% H_2SO_4 gives a slight brown flocculation which dissolves in dil. NaOH, while the degradation solns., also contg. MeO, of materials which show no loss of lignin form no such flocculations. Whether the MeO-contg. substances which, when they dissolve, produce a loss of lignin belong to the carbohydrate series or are true lignin units, perhaps rendered sol. only because of a smaller degree of polymerization when they are liberated, could not be established. Nevertheless, from the fact that in every case the extent of degradation as detd. from the loss in wt. agrees within the limits of exptl. error with that calcd. from the sugar detns., it is evident that the substances in question behave like carbohydrates under the conditions of the Willstätter-Schudel method. In addn. to the age and extent of lignification of the substrate, the nature of the enzyme also influences, in some as yet unexplained manner, the extent of the degradation. Thus, when samples of young and an old elder-tree pith were degraded with a not very active enzyme prepn., the young pith was much more readily attacked than the old pith and the latter even on subsequent treatment with a more active enzyme could not be degraded more than about 30%, but when it was treated from the very first with the stronger enzyme it was degraded to as great an extent as the young pith. With the weaker enzyme the degradation of the old pith (contg. 18.5% lignin) stopped at 26.8%. The residue contained 24.8% lignin whose MeO content was 14.77% as against 19.66% in that of the original pith. In the H_2SO_4 used for the lignin detn. was found 92% of the theoretical amt. of polysaccharides. The pentosan content of the residue was 18.4%, hence the residue was made up of 0.439 mol. polysaccharides (0.304 mol. hexosan and 0.135 mol. pentosan) and 0.135 mol. lignin. Starting with the strong enzyme from the beginning, the old pith was degraded 63%. The residue consisted of 0.303 mol. polysaccharides (0.237 mol. hexosan and 0.066 mol. pentosan) and 0.309 mol. lignin; the MeO content of the lignin was 12.13%. The young pith was 70.7% degraded; the residue consisted of 0.279 mol. polysaccharides (0.206 mol. hexosan and 0.073 mol. pentosan) and 0.259 mol. lignin, and the lignin contained 16.33% MeO as against 18.80% in that of the original pith. Hence, even in these easily degraded materials the enzymic degradation does not lead directly to lignin; rather, there seem to be 2 kinds

of degradation, giving definite residues in which the polysaccharides and lignin bear to each other mol. ratios which are whole nos. VI. **The state of combination of lignin in wood.** *Ibid.* 74–8.—It had been found (part III) that the residue (R), which remains undissolved when linden wood is treated with $(CH_2NH_2)_2$-CuO and forms the greater part of the material, was degraded only 18.6% by enzymes, and as it contained 60.5% cellulose and 20.55% lignin, it was suggested that the enzymic degradation affected only the hemicelluloses (18.5%). The residue should then consist of 3 parts by weight of carbohydrate to 1 of lignin. The fraction (F) pptd. from the $(CH_2NH_2)_2$-CuO soln. by acids was much more readily attacked by enzymes (51.4%). As it contained 26.14% lignin, the opinion was expressed that the rapid hydrolysis stops when the residue consists of equal parts of lignin and carbohydrate units. By continued action of the enzyme the degradation could be pushed somewhat further, to be sure, but only very slowly (an addnl. 13.4% in the same length of time required for the first 54.8%). Furthermore, after the ratio carbohydrate.lignin = 1·1 has been reached, the properties of the substrate change. The residue now remains practically unchanged in compn., behaving like a difficultly degraded, homogeneous substance. The residue from the degradation of R consisted of 0.434 mol. polysaccharides (0.389 mol. hexosan and 0.045 mol. pentosan) and 0.129 mol. lignin, the residue from F of 0.323 mol. polysaccharides (0.268 mol. hexosan and 0.055 mol. pentosan) and 0.300 mol. lignin. Unlike those of young plant material (see part V above) the lignins in the degradation residues were not poorer in MeO than the lignins in the original materials. Hence in fractions R and F there is no loss of lignin, irrespective of the extent of enzymic degradation. This was also found to be true of the elder-tree pith samples; only araucaria pith showed some loss of lignin. It is a striking fact that the enzymic degradation of these different materials yields resistant residues of analogous compn. as shown by the following values for hexosan, pentosan, polysaccharides, lignin (all in mol. %) ratio polysaccharide/lignin, and ratio lignin/pentosan, resp.: old elder-tree pith (sample I) 55.1, 21.8, 76.9, 23.1, 3.32, 1.06; old elder-tree pith (sample III, with weak enzyme) 52.9, 23.5, 76.4, 23.5, 3.25, 1.00; linden fraction R 69.2, 7.9, 77.1, 22.9, 3.36, 2.90; araucaria pith 38.3, 11.9, 50.2, 49.8, 1.01, 4.18; young elder-tree pith 38.3, 13.5, 51.8, 48.2, 1.07, 3.57; old elder-tree pith (sample III, with active enzyme) 38.7, 10.8, 49.5, 50.5, 0.98, 4.68; linden fraction F 43.0, 8.8, 51.8, 48.2, 1.07, 5.47. Since the degradation of these easily degraded materials comes to a stop when the residue consists of equal parts of carbohydrate and lignin, there must be an inner relationship between these components. What the nature of this complex is, the available data do not show. It might be a chem. combination, such as a glucosidic lignin-carbohydrate union. Furthermore, there may be structural units of a still higher order, such as that obtained from old elder-tree pith with a weak enzyme, contg. 3 parts carbohydrate to 1 of lignin and broken down by a stronger enzyme prepn. to a 1·1 complex. C. A. R.

Synthesis of α,α-dimethyltricarballylic and 1-carboxycyclopentane-1-α-succinic and 1-carboxy-3-methylcyclopentane-1-α-succinic acids. R. D. Desai and G. S. Sahariya. *J. Univ. Bombay* **8**, Pt. 3, 235–8(1939). —When in RR'C(CN)C(CN)CO_2Et, R and R' together are cyclopentane or methylcyclopentane rings, there are obtained with CH_2BrCO_2Et (I) excellent yields of tricarballylic acids which are characterized by their toluidide *N*-tolylimides. A mixt. of the Et sodiocyanoacetate (II) from 24 g. cyanoacetate and 21 g. cyclopentanone cyanohydrin is allowed to stand for 48 hrs. After addn. of 32 g. I the mixt. is kept at room temp. for 2 days and then refluxed until it is neutral. The EtOH is distd. off, the residue dild. with H_2O and the oil extd. with ether, dried and distd. into 3 fractions, b_4 90–120°, 120–65° and 185–7°. The 2nd fraction is retreated with I. *Et 1-cyanocyclopentane-1-α-cyanosuccinate* (III), b_4 185–7°, is obtained in 45% yield. **Hydrolysis of III with concd. H_2SO_4 gives 1-carboxycyclopentanesuccinic acid (IV), m. 165°** (cf. Chatterji, *C. A.* **31**, 7409[7], found 159°). Its anilide *N*-phenylimide, prepd. by heating IV with $PhNH_2$ at 170–5° for 3 hrs., m. 156°; *p-toluidide N-p-tolylimide* m. 189–90°. *Et 1-cyano-3-methylcyclopentane-1-α-cyanosuccinate* (V), prepd. as II, b_{12} 205°. Hydrolysis of V gives 1-carboxy-3-methylcyclopentanesuccinic acid, m. 144°; its *p-toluidide N-tolylimide* m. 167°. *Di-Et 2-methyl-3,3-dicyanobutane-3,4-dicarboxylate* (VI), prepd. from II, $Me_2C(OH)CN$ and I, in 45% yield, b_5 176–8°. Sapon. of VI with H_2SO_4 gives α,α-dimethyltricarballylic acid, m. 160° (C, found 156°). Its *anilide N-phenylimide* m. 140°; the *p-toluidide N-p-tolylimide* m. 170°. F. E. Brauns

Influence of groups on the formation of certain tricyclic compounds. Tejendra Nath Ghosh. *Science and Culture* **5**, 372–3(1939); cf. *C. A.* **30**, 2553[9].—It was previously shown that the formation of the tricyclic compd. (II) from the cyclobutane deriv. (I) is conditioned by the at. vol. of the group R, the greater the vol. the greater tendency of I to pass into II with the elimination of 2 mols. of alc. An attempt is now made to explain this influence of

the group R on the basis of the theory of valency deflection of Thorpe and Ingold (Beesley, I. and T., *C. A.* **9**, 3059). If R has a high at. vol. the angle (α) between the valency directions will be smaller (III); the interat. distances (d) between the C atoms will decrease and the groupings "A and C" and "B and D" will come closer and form II. Mark Plunguian

Thiocyano derivatives of hydnocarpic and chaulmoogric acids. Herbert Arnold. *Arch. Pharm.* **277**, 206–11 (1939).—Hydnocarpic acid and $(CNS)_2$ (prepared *in situ*) in AcOH give *2,3-dithiocyanodihydrohydnocarpic acid*. Impure *Et 2,3-dithiocyanodihydrochaulmoograte* is similarly prepd. *3-Thiocyanodihydrochaulmoogric acid* (*Et ester*, $b_{0.3}$ 200–30°) is obtained from the 3-bromo acid by NaCNS in AcOH. None of these products (all oils) cures leprosy in mice. B. C. P. A.

Epimeric alcohols of the cyclohexane series. III. Glucoside formation. D. T. C. Gillespie, A. Killen Macbeth and J. A. Mills. *J. Chem. Soc.* **1940**, 243–5; cf. *C. A.* **34**, 844. —Miescher and Fischer (*C. A.* **33**, 4994[8]) concluded that glucoside formation could be applied as a criterion of trans configuration, since borneol but not isoborneol reacted with bromotetraacetylglucose (I). *l*-Menthol (6 g.), 20 g. I and 10 g. Ag_2O in ether, shaken 60–70 hrs. at room temp., give 11 g. of *tetraacetyl-l-menthyl-d-glucoside*, m. 129.5°, $[\alpha]_D$ −90.3° (EtOH, *c* 2.02); *d-neomenthyl isomer*, m. 144.5°, $[\alpha]_D$ 3.3° (EtOH, *c* 2.073); *dl-isomenthyl isomer*, m. 103–5°; *dl-neoisomenthyl isomer*, m. 128–30°. *Tetraacetyl-cis-dihydrocryptylglucoside*, m. 102°, $[\alpha]_{5461}$ −32.8° (EtOH, *c* 1.93); *trans isomer*, m. 107.5°, $[\alpha]_{5461}$ −25.8° (EtOH, *c* 1.96). *Tetraacetyl-trans-l-3-methylcyclohexyl-d-glucoside*, m. 103°, $[\alpha]_{5461}$ −31.5° (EtOH, *c* 1.97); *cis isomer*, m. 105°, $[\alpha]_{5461}$ −38.9° (EtOH,

c 2). *Tetraacetyl-trans-4-methylcyclohexylcarbinylglucoside* (II), m. 113°, $[\alpha]_D^{25}$ −28.6° (EtOH, *c* 1.92); *cis isomer*, m. 72–3°, $[\alpha]_D^{25}$ −23.4° (EtOH, *c* 1.97). *trans-4-Isopropyl analog* of II, m. 112°, $[\alpha]_D^{25}$ −26.9° (EtOH, *c* 2.08); *cis isomer*, m. 103–4°, $[\alpha]_D^{25}$ −25.8° (EtOH, *c* 1.96). *Tetraacetyl-trans-l-cryptylglucoside*, m. 99–9.5°, $[\alpha]_D$ −80.6° (EtOH, *c* 2.27); *cis isomer*, m. 106.5°, $[\alpha]_D^{25}$ −90.7°. This work makes the conclusion of M. and F. untenable. C. J. West

Dehydration of some tertiary alcohols containing the cyclohexane ring. Wm. A. Mosher. *J. Am. Chem. Soc.* **62**, 552–4(1940).—In order to obtain data on the manner of dehydration of tertiary alcs. contg. the cyclohexane ring, as well as to gain some insight into the process as applied to the group as a whole, 1-Me, 1-Et, 1-iso-Pr and di-Me derivs. of cyclohexanol have been prepd. and dehydrated; dehydration was effected by heating with I under a column so that the olefin and H_2O distd. out of the mixt. as formed. The use of ozonolysis offers a simple and satisfactory approach to the problem as it makes phys. sepn. of the isomers unnecessary. The 1-Me deriv. gave no HCHO, indicating that no methylenecyclohexane was formed and that only 1-methylcyclohexene was formed by the dehydration. In the case of the 1-Et deriv. only a trace of AcH was found, indicating that less than 1% of ethylidenecyclohexane was formed; the other 99% was probably 1-ethylcyclohexene. An amt. of Me_2CO corresponding to approx. 5% of the theory was found in the products from the 1-iso-Pr deriv., indicating this percentage of isopropylidenecyclohexane in the olefin mixt. The di-Me deriv. gives approx. 50% each of Me_2CO and HCHO, indicating equal amts. of isopropylidenecyclohexane and isopropenylcyclohexane in the mixt. Dehydration apparently will take place in such a manner that the double bond occurs principally in the ring when this is possible; in other words, the H atoms attached to the ring are less firmly bound than those of a more aliphatic nature. It is noted that a proton is lost from the cyclohexane ring more readily than from a Me, Et or iso-Pr group. C. J. West

Methylation of ethyl methylcyclohexylidenecyanoacetates and reduction of ethyl 2-methylcyclohexylidenecyanoacetate. R. D. Desai and G. S. Sahariya. *J. Univ. Bombay* **8**, Pt. 3, 239–42(1939).—Et 4-methyl-, 3-methyl- and 2-methylcyclohexylidenecyanoacetates (I, II, III) are methylated in the presence of EtONa in order to study whether they are tautomerized to the β,γ-form similar to the Et cyclohexylidenecyanoacetate (cf. Kon and coworkers, *C. A.* **17**, 2870). I (16 g.) is added to 2 g. Na in 40 cc. EtOH and 20 g. MeI is added to the mixt. After standing for 4 hrs. at room temp. and heating for 1 hr. on a water bath, the mixt. is dild. with H_2O and extd. with ether. *Et α-cyano-α-4-methylcyclohexenylpropionate* (IV), b_{12} 152–4°. IV readily adds Br. When 7 g. IV is treated with 0.7 g. Na in 15 cc. MeOH at 35° for 5 hrs. and the pptd. oil is extd. with ether, dried and distd., *α-4-methylcyclohexylidenepropionitrile*, b_{12} 106°, is obtained, which on oxidation with $KMnO_4$ yields 4-methylcyclohexanone. In the same way II gives *Et α-cyano-α-3-methylcyclohexenylpropionate*, b_{12} 146–7°, and *α-3-methylcyclohexylidenepropionitrile*, b_{12} 107–8°. III gives *Et α-cyano-α-2-methylcyclohexenylpropionate*, b_{12} 144–5°, and *α-2-methylcyclohexylidenepropionitrile*, b_{12} 110°. Reduction of III with Al-Hg in moist ether gives *Et 2-methylcyclohexylcyanoacetate*, b_{12} 135–6°, which, when sapond. by refluxing it with alc. KOH, gives 2-methylcyclohexylmalonic acid, m. 154°. No bimol. product is obtained such as was found by Vogel and Oommen (*C. A.* **24**, 3225) on reduction of I and II with Al-Hg. F. E. Brauns

Identification of organic compounds. I. Chlorosulfonic acid as a reagent for the identification of aryl halides. Ernest H. Huntress and Frederick H. Carten. *J. Am. Chem. Soc.* **62**, 511–14(1940).—The object of this work was to find a set of conditions such that treatment of the sample with $ClSO_3H$ would yield readily the corresponding arylsulfonyl chloride which in turn could be converted to the sulfonamide. The process of introducing the $-SO_2Cl$ group is designated as *chlorosulfonylation*. Two standard procedures are used, the 1st of which uses $CHCl_3$ as a solvent; the 2nd uses no solvent. The yields of arylsulfonyl chloride thus obtained are generally 60–90%. Conversion to the amide is effected by treatment with concd. NH_4OH or with solid $(NH_4)_2CO_3$, the yields being nearly quant. In a few cases the reaction with $ClSO_3H$ is abnormal. PhF without solvent yields 71–4% of *4,4'-difluorodiphenyl sulfone*, m. 97–8°; heating at 40° for 1 hr. gives a 100% yield. PhI gives the *4,4'-di-I analog*, m. 201–2°. *o*-$C_6H_4Cl_2$ gives *3,4,3',4'-tetrachlorodiphenyl sulfone*, m. 175–6° (3–4% of 3,4-$Cl_2C_6H_3SO_2NH_2$ is also formed); *o*-$C_6H_4Br_2$ gives the *3,4,3',4'-tetraBr analog*, m. 176–7°. *p*-$C_6H_4I_2$, heated with 5 parts $ClSO_3H$ at 50° for 5 min., gives *2,3,5,6-tetrachloro-1,4-diiodobenzene*, m. 210–11°. 1,2,4,5-$C_6H_2Cl_4$ (5 g.) and 20 g. $ClSO_3H$, refluxed 1 hr., give 78% of C_6Cl_6. *p*-ClC_6H_4Br and 5 parts $ClSO_3H$, refluxed 1 hr. and the chloride reacted with NH_3, give 86% of 2,5-$BrClC_6H_3SO_2NH_2$, m. 189–90°. M. ps. are given for 28 sulfonamides (6 are new but are not indicated) and for 4 sulfones (2 new). Derivs. of C_6H_6 studied: Cl, Br, F, 1,2-, 1,3- and 1,4-di-Cl and -di-Br, 1,2,3-, 1,2,4- and 1,2,5-tri-Cl and 1,3,5-tri-Br; of PhMe: 2-, 3- and 4-Cl, -Br and -F and 2,4- and 2,6-di-Cl; of $C_{10}H_8$: 1- and 2-Cl and -Br. Since the 3 isomeric $C_6H_3Cl_3$ yield sulfonamides which are not well adapted for their pos. identification, the utility of nitration for this purpose was studied; soln. of 1 g. in 5 g. fuming HNO_3 gives a quant. yield of the mono-NO_2 deriv.; addn. of 5 g. concd. H_2SO_4 to the HNO_3 soln. and refluxing 1 hr. give a quant. yield of the di-NO_2 deriv. Heating 4,5,6,1,3-$Cl_3C_6H(NO_2)_2$ with $PhNH_2$ for 1 hr. on the water bath gives *4,6-dianilino-5-chloro-1,3-dinitrobenzene*, m. 136–8°; *2,6-dianilino isomer*, m. 182°. III. **Chlorosulfonic acid as a reagent for the characterization of aromatic ethers.** *Ibid.* 603–4.—The use of $ClSO_3H$ has been extended to 36 aromatic ethers. In the following the parent ether and the yield of the amide are given and m. ps. are recorded for the new derivs. of *benzenesulfonamide:* PhOMe 53 (*p-MeO*, m. 110–11°); PhOEt 78; PhOPr 68 (*p-propoxy*, m. 116–17°); PhOBu 35 (*p-butoxy*, m. 103–4°); *o-*, *m-* and *p*-MeC_6H_4OMe 84, 69, 86, resp.; *o-*, *m-* and *p*-MeC_6H_4OEt 71, 61, 77, resp. (*3-methyl-4-ethoxy*, m. 148–9°; *2,4-isomer*, m. 110–11°); *p*-MeC_6H_4OPr 54 (*2-propoxy-4-methyl*, m. 126–7°); *o*-MeC_6H_4OBu 44 (*4-butoxy-5-methyl*, m. 95–6°); *o*-$C_6H_4(OMe)_2$ 89; *m*-isomer 53; *p*-isomer 53 (*2,5-dimethoxy*, m. 148°); *o*-$C_6H_4(OEt)_2$ 81 (*3,4-di-EtO*, m. 162–3°); *m*-isomer 59 (*2,4-di-EtO*, m. 184–5°); *p*-isomer 47; 1,2,3-$C_6H_3(OMe)_3$ 29 (*2,3,4-tri-MeO*, m. 123–4°); *o-* and *p*-ClC_6H_4OMe 85, 82; *o-* and *p*-BrC_6H_4OMe 78, 81 (*3-bromo-4-methoxy*, m. 139–40°; *5,2-isomer*, m. 147–8°); *p*-FC_6H_4OMe 86 (*5-fluoro-2-methoxy*, m. 174–5°); *o-* and *p*-ClC_6H_4OEt 73, 71 (*3-chloro-4-ethoxy*, m. 132–3°; *5,2-isomer*, m. 134–4.5°); *o-* and *p*-BrC_6H_4OEt 76, 68 (*3-bromo-4-ethoxy*, m. 134–5°; *5,2-isomer*, m. 144–4.5°); *p*-BrC_6H_4OPh 67. *α-* and *β*-$C_{10}H_7OMe$ 55, 65 (*4-* and *7-methoxynaphthalenesulfonamides*, m. 156–7° and 150–1°); *α-* and *β*-$C_{10}H_7OEt$ 64, 58; Ph_2O 86; $(CH_2OPh)_2$ 74 (*α,β-diphenoxyethane-4,4'-disulfonamide*, m. 228–9°); $CH_2(CH_2OPh)_2$ 44 (*α,γ-diphenoxypropane-4,4'-disulfonamide*, m. 245–55°). Satisfactory monochlorosulfonylation could not be obtained with *o-* and *p*-$MeOC_6H_4Ph$, $PhCH_2OMe$, $PhCH_2OEt$, diphenylene oxide and $(4\text{-}BrC_6H_4)_2O$. The color usually observed during the reaction varies from pale yellow to brown. C. J. West

Iodoso compounds as oxidizing agents. Rudolf Criegee and Hans Beucker. *Ann.* **541**, 218–38(1939).—The reaction velocity of anethole with $RI(OAc)_2$ in AcOH at 20° falls in the order R = *p*-MeC_6H_4, *m*-4-xylyl (I), *m*-MeC_6H_4, *o*-MeC_6H_4, Ph (II), *p*-$PhO_2SC_6H_4$, *p*-$O_2NC_6H_4$ (III); the bimol. coeffs. gradually decrease with time in all cases and are all of the same order (as is that for $Pb(OAc)_4$ (IV)). Previous work with cyclopentadiene (V) and IV (*C. A.* **24**, 5286) showed that besides the normal addn. product ($1,2\text{-}C_5H_8(OAc)_2$) there was also obtained $1,2\text{-}C_5H_8(OAc)OCOCH_2OAc$ (VI). V reacts with I, II or III in AcOH at 30° within a short time to give 52–73% of a mixt. of diacetoxycyclopentenes (VII) but VI could not be detected. Hydrolysis of VII and hydrogenation give a mixt. of cyclopentanediols (VIII). Destruction of

the 1,2-isomers of VIII shows that 43–60% consists of these isomers; the remainder consists of the 1,3-isomers of VIII, b_1 85–93° (*bisphenylurethans*, m. 142° and 173°). The 1,2-isomers contain 41–59% of the cis and 59–41% of the trans compd. IV in AcOH gives 57% of the 1,2-isomer (76% cis form) and 43% of 1,3-isomer and in C_6H_6, 81% of the 1,2-diol (96% cis form) and 19% of the 1,3-diol. The production of the 1,3-diol shows preliminary 1,4-addn. of 2 AcO groups to the conjugated system. Fissions of α,β-glycols by II occur much more slowly than with IV; the reaction is bimol. and the velocity coeffs. at 20° are (values for IV given first for comparison): *cis*- and *trans*-diphenylacenaphthenediol 33,000, 115; 284, 1.21; isohydrobenzoin (IX) 2820, 0.28; *cis*- and *trans*-diphenyldihydrophenanthrenediol 286, 0.073; 24.7, 0.0084; *cis*-decalin-9,10-diol 15, 0.0084; *cis*- and *trans*-cyclohexanediol 5.04, 0.0008; 0.224, very small. It is probable that the reaction proceeds through the cyclic intermediate .C.O.IPh.O.C:. Data are given for k_{20} for IX and the half-period time for anethole and IX with 12 iodosoacetates; in general the results for IX are the reverse of those for anethole. There is no simple relationship between the reaction velocity and the strength of the acid in the oxidation of IX by derivs. of PhIO; k_{20} for the acetate, chloro-, dichloro- and trichloroacetates are 2, 9.4, 10.4 and 8.3, resp. Iodochlorides are not capable of splitting glycols and free PhIO does not lend itself because of its insoly. in all solvents. Oxidation of $(CO_2H)_2$ with I–III gives k_{20} values of 2.45, 7.33 and 15.2, resp. $PhCH(OH)CO_2H$ and PhIO in H_2O-C_6H_6 give 88% of BzH. *Iodosobenzene monochloroacetate*, $PhI(O_2CCH_2Cl)_2$, decomps. 116°, 65% yield upon rubbing 11.5 g. of PhIO and 10 g. $ClCH_2CO_2H$ in a mortar and crystg. from C_6H_6; *dichloroacetate*, $PhI(O_2CCHCl_2)_2$, decomps. 112°, by addn. of PhIO to a concd. soln. of Cl_2CHCO_2H in C_6H_6. C. J. West

Action of aromatic amines on 3-nitro-6-iodonitrostyrene. David E. Worrall and Frederick Benington. *J. Am. Chem. Soc.* **62**, 493–4(1940); cf. *C. A.* **33**, 1284⁹.—*o*-IC_6H_4CHO and $MeNO_2$ in Et_3N give 65–70% of *α-nitro-β-(2-iodophenyl)ethylene* (I), pale yellow, m. 113–14°; fuming HNO_3 gives *α-nitro-β-(6-iodo-3-nitrophenyl)ethylene* (II), pale yellow, m. 145–6°. I and Br give an oil on treatment with warm EtOH-AcOK; fuming HNO_3 gives a yellow *compd.*, $C_8H_4BrIN_2O_4$, m. 136–7°; it gives an addn. compd. with *p*-$MeC_6H_4NH_2$ but was not investigated further. The previous procedure was used for prepg. the *addn. compds.* of II, which were crystd. from EtOH; they are yellow or orange-yellow and are deeper in color than II; *β-derivs.* of α-nitro-β-(6-iodo-3-nitrophenyl)ethane: *anilino*, m. 115–16°; *o-*, *m-* and *p-toluidino*, m. 168–70°, 113–14° and 130–2°; *o-*, *m-* and *p-anisidino*, m. 146–8°, 140–2° and 123–4°; *phenylhydrazino*, m. 142–4°; *β-naphthylhydrazino*, m. 143–4°; *hydroxylamino*, m. 103–5°; *semicarbazido*, m. 187–8° (the last 2 are colorless) II in. C_6H_6, satd. with NH_3 and allowed to evap. spontaneously, gives *α,α'-di(6-iodo-3-nitrophenyl)-β,β'-dinitrodiethylamine*, m. 113–14°. II is the most active nitrostyrene thus far studied. C. J. West

Action of nitrous acid on *p*-nitrodimethylaniline in hydrochloric acid. Henrietta Margaret Halliday and Thomas H. Reade. *J. Chem. Soc.* **1940**, 138–41.—In the reaction of substituted $PhNMe_2$ with HCl and $NaNO_2$, the fate of the Me group and the mechanism of the reaction are studied. Quant. results were unreliable in the presence of air. The largest yield of *p*-$O_2NC_6H_4N(NO)Me$ (I) from *p*-$Me_2NC_6H_4NO_2$ (II) in 5 *N* HCl in a N atm. was obtained when 5.5 mols. of $NaNO_2$ were used for each mol. of II; for every mol. of II decompd., 1.5 mols. of gas were evolved, consisting of NO and N in the proportion 93.7:6.3; there was only a trace of CO_2 in the gas. A max. yield of HCHO was obtained with 2 mols. of $NaNO_2$, falling almost to 0 when large amts. of nitrite were used; 2.2 mols. of $NaNO_2$ were required to decomp. 1 mol. of HCHO in 5 *N* HCl; the evolved gases accounted for 95.5% of the N in the original nitrite as NO with 6% N; they were free of CO and CO_2; most of the C remained in the aq. acid but attempts to isolate org. substances from the dil. soln. were unsuccessful, although from concd. solns. small quantities of substances m. 55° and 95–100° and 0.15 mol. of carbonate were obtained. The reactions involved are: $2II.HCl + 3HNO_2 \rightarrow 2O_2NC_6H_4NHMe.HCl$ (III) + $2HCHO + 3NO + H_2O + (H)$; $III + HNO_2 \rightarrow I + HCl + H_2O$; $HCHO + 2HNO_2 \rightarrow 2NO +$ unidentified org. compds. The NO always contains about 6% N, attributed to the action of H from the 1st equation not actually liberated as such. Attempts to ascertain the order of the reaction between $NaNO_2$, HCHO and HCl by estg. the rate of decompn. of the HCHO at different dilns. gave conflicting results; in some expts. the HCl probably performed some function other than merely liberating the HNO_2 from the nitrite. The results are given in 5 sets of curves. C. J. West

Condensation of butyraldehyde with aniline. M. S. Kharasch, Isadore Richlin and Frank R. Mayo. *J. Am. Chem. Soc.* **62**, 494–7(1940).—$PhNH_2$ and PrCHO (both freshly distd.), mixed with stirring and cooling and allowed to stand for 18–24 hrs., give 78% of butylideneaniline dimer (I), PhN:CHCHEtCHPrNHPh, m. 92.5°; the purest material in the best yield is obtained by the complete absence of acid (by addn. of a small amt. of aq. Na_2CO_3 to the reaction and to the EtOH used for crystn.). The mol. wt. of I in Ph_3CH is 281.4 (calcd. 294.4); in camphor the values vary from 176 (5% soln.) to 251 (10% soln.), indicating dissocn. If H_2O and acid are excluded, up to 75% of pure crystals can be recovered from vacuum distn. of the I. I takes up 1 mole of H on catalytic reduction, giving an oil b_{20} 240–50°; the di-Ac deriv. (*1,3-diacetanilino-2-ethylhexane*) m. 131°. In the presence of small amts. of acid, as when an old PrCHO is used or when as little as 0.03 mole % of AcOH or $PrCO_2H$ is added to the reaction, the product is the *anil* (II) of α-ethyl-β-propylacrolein (III), PhN:CHCEt:CHPr, yellow, b_{18} 146–8°; cryst. I may or may not sep. during the reaction. II is formed from I on standing in the air for several days. II with BzCl in C_6H_6 gives 93% of PhNHBz and AcCl gives 60% of PhNHAc. 2,4-$(O_2N)_2C_6H_3NHNH_2$ and H_2SO_4 with II or III give the 2,4-dinitrophenylhydrazone of III, m. 119–20°; the yield from II is 60%. II results in 70% yield from III and $PhNH_2$. Using PrCHO and $PhNH_2$ in the ratio of 2:1 and adding 0.1, 0.5, 1, 1.5, 2 and 5 moles of HCl per mole $PhNH_2$ (20–24 hrs. at room temp.) there results 20, 58, 79, 60, 56 and 54% of 3-ethyl-2-propylquinoline (V); I and 1 mole HCl give 50% V; II and 2 moles HCl give 15% V; II and $PhNH_2$ with 1 mole HCl give 20% V; $PhNH_2$ and II with 2 moles HCl give 15% V. V is isolated and identified as the picrate. By-products of the Doebner-Miller synthesis of V are *N*-butylaniline (67% of the yield predicted on the basis of V formed) (*naphthylurea*, m. 277°) and a fraction b_{18} of over 200°, which may contain di- and tetrahydro derivs. of V. The compd. of V described by Kahn (*Ber.* **18**, 3361(1885)) is the *HI salt*, m. 171–2° (also prepd. from V and HI in ligroin); V forms a *methiodide*, m. 160–5°. A mechanism is suggested for the Doebner-Miller synthesis. C. J. West

Action of chlorine on aryl thiocarbimides and the reactions of aryl isocyanodichlorides. G. Malcolm Dyson and Thomas Harrington. *J. Chem. Soc.* **1940**, 191–4.—PhNCS (20 g.) in 64 g. $CHCl_3$, treated with Cl without cooling until the increase in wt. is 2 g., gives *bis(phenylthiocarbimide) oxide*, yellow, m. 118°; *p-tolyl analog*, m. 139°; *m*-isomer, m. 128°; *p-bromophenyl analog*; no oxides were obtained from *o*-MeC_6H_4NCS or from *o-*, *m-* and *p*-$O_2NC_6H_4NCS$. PhNCS (20 g.) in 10 g. $CHCl_3$, treated with Cl until the increase in wt. is 7 g., gives 1-anilinobenzothiazole (I), m. 159° (picrate, yellow, m. 221°). $CS(NHPh)_2$ and Br in $CHCl_3$, boiled 0.5 hr., give red needles of a Br addn. product; reduction with SO_2 in H_2SO_3 and treatment with hot 2 *N* NaOH give I. PhNCS (318 g.) in 289 g. PhN:CCl_2 (II), treated with Cl with cooling for 8 hrs. (increase in wt. of 363 g.) gives 256 g. of II, b. 209–11°, d^{16} 1.285; the following isocyanodichlorides were prepd. by treatment with Cl in 2–3 times their wt. of CS_2; they are colorless or pale yellow lachrymatory oils with unpleasant odors: *p-bromophenyl*,

b_{15} 122–4°, d^{15} 1.5; *p-anisyl*, b_{15} 155–60°, d^{15} 1.5; *p-tolyl*, b_{20} 121–4°, d^{15} 1.2; *m-tolyl*, b_{10} 130°, d^{15} 1.35; *o-tolyl*, b_{15} 125–30°, d^{15} 1.3; *m-nitrophenyl*, prepd. in warm $CHCl_3$, pale yellow, b_{15} 165–70°, m. 68°; *m-isomer*, m. 80°; the *o*-isomer could not be prepd. II (5 g.) and 3.5 g. AcOH in 20 cc. C_6H_6, refluxed 2 hrs., give $CO(NHPh)_2$ (III); the *o*- and *p*-tolyl analogs were similarly obtained; however, boiling 10 g. II with 25 cc. AcOH in 50 cc. C_6H_6 for 10 hrs. gives PhNHAc (IV); *o*-, *m*- and *p*-MeC_6H_4NHAc were similarly prepd. Thus the reaction with AcOH proceeds as follows: $2II + 3AcOH \rightarrow III + CO_2 + HCl + 3AcCl$; $III + AcCl + AcOH \rightarrow 2IV + CO_2 + HCl$. III is only very slowly hydrolyzed to IV by AcOH alone whereas in the presence of AcCl the reaction is rapid and proceeds to completion. The *m*-tolyl analog yields an unidentified N compd. m. 278°. *p*-$BrC_6H_4N{:}CCl_2$ and AcOH in C_6H_6 give $(p\text{-}BrC_6H_4NH)_2CO$ on refluxing 5 hrs. and *p*-BrC_6H_4NHAc on further boiling; *m*-$O_2NC_6H_4N{:}CCl_2$ behaves similarly. II, $PhNH_2$ and C_6H_6, refluxed 5 hrs., give triphenylguanidine-HCl; analogs were prepd. as follows, the m. p. of the HCl salt and the free base being given: *phenyldi-p-tolyl* 222–3°, 109°; *m-isomer* 206, 93°; *o-isomer* 205°, 100°; *phenyldi-p-bromophenyl* 257 62°, oil; *p-tolyldiphenyl* 230°, 128°; *tri-p-tolyl* 231°, 125°; *p-tolyldi-p-bromophenyl* 262–6°, 178°; *tri-m-tolyl* 221°, 107°; *m-tolyldi-p-tolyl* 218°, 105°; *tri-o-tolyl* 213–15°, 129°; *o-tolyldi-p-tolyl* 205–8°, 87°; *tri-p-bromophenyl* 270 6° (decompn.), 126°; *p-bromophenyldi-p-tolyl* 251°, 123°; *m-nitrophenyldi-p-tolyl* 201–5°, 179°; *m-tolyl isomer* 218 25°, 139°. The method constitutes a simple approach to the unsym. guanidines. C. J. West

Hydration of stearanilide. B. A. Toms. *Nature* **145**, 227(1940). The formation of hydrated stearanilide is described. After drying, the prepn. contained almost 80% water. E. D. Walter

***p*-Cymene studies. IV. Mononitration of 2-amino-*p*-cymene. Preparation of 3-amino-*p*-cymene and *o*- and *p*-cymylenediamine.** Thomas F. Doumani and Kenneth A. Kobe. *J. Am. Chem. Soc.* **62**, 562–5(1940); cf. *C. A.* **33**, 4209[2,4].—2-Amino-*p*-cymene (1 mol.) and 1.76 mols. HCO_2H, refluxed for 2 hrs., give the *formyl deriv.*, m. 108.8–9.4° (all m. ps. cor.); nitration with HNO_3 in H_2SO_4 at 0° gives 90% of crude formyl deriv. and hydrolysis with 30% NaOH (refluxing 1 hr.) gives 99% of the isomeric nitramines. Fractionation of 98.2 g. gives 64.5 g. b_1 114–16° (I) and 26.6 g. b_1 144 8°, m. 57–60° (II). I is *2-amino-3-nitro-p-cymene*, b_5 142.9°, b_{20} 175.6°; it is purified through the *Ac deriv.*, m. 167.6–7.8° (refluxing with Ac_2O for 3 hrs.); *formyl deriv.*, m. 139.6–40° (refluxing with 90% HCO_2H for 5 hrs.); *Bz deriv.*, m. 193.4–3.8° (BzCl at 90° for 5 min.). The yield of I is 70%. Reduction of 35 g. I in 35 ml. EtOH and 30 ml. 30% NaOH with Zn (addn. so that the soln. gently refluxes and then refluxing for an addnl. hr.) gives 26 g. (88%) of *o-cymylenediamine* (III), m. 95–5.8°; *di-Ac deriv.* (IV), m. 235.1–5.3° (formed by soln. of III in Ac_2O); refluxing III in Ac_2O for 1 hr. gives a mixt. of IV and V. Distn. of IV at atm. pressure (b. 326–7°) gives *2,7-dimethyl-4-isopropylbenzimidazole* (V), m. 179.5–9.9°; V also results on refluxing III in glacial AcOH for 1 hr.; V forms salts with mineral acids. Refluxing III, benzil and EtOH for 15 min. gives *2,3-diphenyl-5-isopropyl-8-methylquinoxaline*, m. 136.7–7.3°; H_2SO_4 gives a blood-red color, changing to yellow on diln. III and phenanthraquinone in AcOH, refluxed 15 min., give *10-isopropyl-13-methyldibenzophenazine*, light yellow, m. 181.2–1.4°; concd. H_2SO_4 gives a purplish red color; concd. HCl gives a yellow color. Fraction II is *2-amino-5-nitro-p-cymene*, canary-yellow, m. 66.6–7.6° (30% yield); *Ac deriv.*, m. 142.8–3.2°; *formyl deriv.*, yellow, m. 101.6–2.2°; *Bz deriv.*, light yellow, m. 139–9.4°. Reduction of II with Zn in 50 ml. EtOH and 25 ml. 40% NaOH gives 86% of *p-cymylenediamine* (VI), b_1 120–5°, m. 50–50.5°; *di-Ac deriv.*, m. 262–2.2°. Oxidation of VI with $FeCl_3$ gives thymoquinone. VI is fairly stable in light; in aq. EtOH it is more rapidly destroyed. Decompn. of the diazo compd. from I with abs. EtOH gives 52% of 3-nitro-*p*-cymene, light yellow, b_{10} 116.7°, b_{20} 133.5°; 20 g. II gives only 2.3 g.; reduction with Fe and HCl gives 3-amino-*p*-cymene, b_{10} 105.7°, b_{760} 240.2°; *formyl deriv.*, m. 106.2–6.6°. Nitration of 2-acetamino-*p*-cymene (which is extremely difficult to purify) gives 52% I and 48% II; nitration of 2-amino-*p*-cymene gives approx. 60% of I and 40% II. This work shows that the compd. of Wheeler and Brooks (*C. A.* **22**, 228), which they believed to be II, is really I. C. J. West

Oxidizability of thioarylhydrazides to disulfides. H. Wuyts and A. Lacourt. *Bull. soc. chim. Belg.* **48**, 193–200(1939); cf. *C. A.* **31**, 4978[8].—The authors present addnl. evidence for the existence of a tautomeric mercaptan form in which thioarylhydrazides undergo reactions. Thus α-phenyl-β-thiobenzoylhydrazine is quantitatively oxidized by I in C_6H_6 to its corresponding *disulfide*, m. 149° ($2PhC(:NNHPh)SH + I_2 \rightarrow [PhC(:NNHPh)S]_2 + 2HI$). Its insoly. in alkali in which the parent hydrazide is sol., its mol. wt., which is twice that of the hydrazide, the presence of 2 active H atoms with respect to Mg and the fact that it can be acetylated, represent the properties upon which its structure is based. Similarly the corresponding disulfides (I and II) were prepd. from α-phenyl-β-(α-thionaphthoyl)hydrazine (m. 161°), and from α-methyl-α-phenyl-β-cyclohexylcarbothioylhydrazine (m. 108°); I m. 165° (EtOH and C_6H_6); II could not be purified because of further oxidation. Attempts to oxidize *p*-$MeC_6H_4C(SMe){:}NNHC_6H_4Me$-*p* failed. This substantiates the conclusion that the hydrazides which forego oxidation exist in a tautomeric mercaptan form. The above-mentioned disulfides are readily reduced to their corresponding thiohydrazides in C_6H_6 soln. upon agitation with a mixt. of $SnCl_2$ and concd. HCl. Reaction of the disulfides with Mg yields the corresponding hydrazide and a mixed sulfide. The latter reaction with the Grignard reagent establishes the presence of a disulfide linkage in the oxidation product of the thioarylhydrazides. W. A. C.

Associating effect of the hydrogen ion. V. Nitroarylhydrazones. Louis Hunter and John A. Marriott. *J. Chem. Soc.* **1940**, 166–70; cf. *C. A.* **33**, 4220[8].—Cryoscopic measurements have been made of the mol. wts. of a no. of NO_2-substituted arylhydrazones over a range of concn. The results provide direct evidence of a type of H-bond assocn. long assumed on theoretical grounds to be operative in certain substances, viz., that due to the union of unlike groups in sep. mols. Two kinds of H-bond assocn. are therefore distinguishable: *homogeneous assocn.*—between typical assocg. groups of the same kind, as in phenols (—OH-------HO—), oximes (:NOH-------HON:), amides (—CONHR-------NHRCO—), etc., and *heterogeneous assocn.*—between electron-donor and electron-acceptor groups of different kinds, e. g., $-NO_2$-------HO—, $-NO_2$-------NHArN=, and presumably many others. PhCH:NNHPh is weakly assocd. Substitution of a NO_2 group in either Ph nucleus causes a high degree of assocn. *o*-$PhCH{:}NNHC_6H_4NO_2$, in which the H bonding can occur intramol., is not assocd. Substitution of a Me or Ph group for the imino-H atom of the $O_2NC_6H_4CH{:}NNHPh$ checks assocn. *m*-$O_2NC_6H_4CMe{:}NNHPh$ is assocd. but *m*-$O_2NC_6H_4CMe{:}NNPh_2$ is not. By dispensing with the NO_2 group (as in PhCMe:NNHPh) and the imino-H atom (as in $PhCMe{:}NNPh_2$) assocn. is again checked. Salicylidene-*o*-nitrophenylhydrazine (I) is unassocd. in $C_{10}H_8$; it is evident that both hydroxyl- and imino H atoms are chelated and therefore not free to undertake intermol. bonding. On the other hand the *p*-isomer (II) is assocd.; it seems clear that assocn. is due to intermol. union of the NO_2 and hydrazone groups. The m.-p. depression of II is 41°, of I 18°. Three solvents were used: C_6H_6, $C_{10}H_8$ (III) and *p*-$C_6H_4Br_2$ (IV). The 3 $O_2NC_6H_4CH{:}NNHPh$ (V), though assocd. in IV, are considerably less assocd. in $C_{10}H_8$; this is due to compd. formation. *o*-V and III form an unstable 1:1 compd., m. 123°; eutectic pt. for mixts. rich in III at 77° and eutectic arrest for mixts. rich in V at 113°. *m*-V and III form an unstable 1:1 compd. m. 85°; eutectic pt. (40% by wt. of III) at 67°. *m-Nitroacetophenone diphenylhydrazone*, bright yellow, m. 105°. C. J. West

Action of mixed organomagnesium compounds on *sym*-acylphenylhydrazines. Panos Grammaticakis. *Compt.*

rend. **207**, 239–41(1938); cf. *C. A.* **31**, 4954.—Although *sym*-acylphenylhydrazines do not react with a mixed organomagnesium compd. in ether, they do so when heated at 116–20° for 7–12 hrs. with a large excess thereof. Under these circumstances *sym*-formylphenylhydrazine and PhMgBr yield mainly Ph_2CO with a very little $Ph_2C{:}NNHPh$ and $Ph_2C{:}NPh$; the *sym*. Ac Ph deriv. gives α-phenylindole and a little $MePhC{:}NNHPh$ and $MeCOPh$; and the *sym*. Bz Ph deriv. gives $Ph_2C{:}NNHPh$, $Ph_2C{:}NPh$, $Ph_2C{:}NH$ and Ph_2CO. In all cases a little $PhNH_2$ and H_2NNHPh are also formed. It is suggested that the formation of some at least of these side-products is due to the organomagnesium interacting with the tautomeric form $RC(OH){:}NNHPh$. C. A. Silberrad

General methods of preparing *sym*- and *asym*-alkylphenylhydrazines. Panos Grammaticakis. *Compt. rend.* **210**, 303–5(1940); cf. *C. A.* **31**, 4952[2]; **34**, 1977[4].—*sym*-Alkylphenylhydrazines are readily obtained in good yield by acting with an alkyl halide or sulfate on the Na deriv. (I) of *sym*-diformylphenylhydrazine (II) and hydrolyzing with cold concd. HCl. (I is prepd. as a white hygroscopic powder by acting with $NaNH_2$ on II in suspension or soln. in ether, C_6H_6 or xylene). In this way *sym*-methyl-, -ethyl-, -benzyl- and -(α-phenylpropyl)-phenylhydrazines were prepd. Other *sym*-diacylphenylhydrazines (e.g., diacetyl, dibenzoyl, succinyl) act similarly. If, however, a *sym*-acylphenylhydrazine is used a mixt. of *sym*- and *asym*-alkylphenylhydrazines is obtained in proportions depending on the exptl. conditions. In place of the Na deriv., complexes such as $MgX(CHO)NNPh(CHO)$ formed by acting with MeMeBr or EtMgBr on the acylphenylhydrazine may be used (cf. preceding abstr.). *sym*-Alkylphenylhydrazines of the type $RCH_2HNNHPh$ are readily oxidized to the hydrazone, whence the aldehydes can be prepd.; in this way benzaldehyde, *o*-, *m*- and *p*-tolualdehyde and *p*- and *m*-anisaldehydes have been prepd. *asym*-Alkylphenylhydrazines (cf. Michaelis, *Ann.* **252**, 266(1889)) are readily obtained by adding H_2NN-PhNa (prepd. by slowly adding NH_2NHPh to a C_6H_6 or ether suspension of NH_2Na) to an equimol. amt. of RX and heating for 5 hrs. In this way *asym*-methyl-, ethyl-, isopropyl- and benzyl-phenylhydrazines have been prepd. C. A. Silberrad

Decomposition of $RHgC_6H_5$ (where R is an acid radical) in alcohols. M. M. Koton. *J. Gen. Chem.* (U. S. S. R.) **9**, 1622–5(1939); cf. *C. A.* **34**, 392[6].—Previously it was shown that derivs. of Ph_2Hg are decompd. in alcs. with sepn. of Hg and formation of the corresponding hydrocarbons. The reaction proceeds with the formation of small quantities of the corresponding free aldehydes and esters. RHgPh, where R is an acid radical, react similarly in MeOH, iso-AmOH and EtOH at 125° and 200°. RHgPh, prepd. by the previous method, are more easily decompd. than Ph_2Hg with sepn. of 75–100% Hg. The rate of decompn. increases with the mol. wt. of the alcs. The rate of decompn. of RHgPh decreases in the following order: HCO_2HgPh, *o*-$HOC_6H_4CO_2HgPh$, $C_3H_6(OH)CO_2HgPh$, $C_2H_4(OH)CO_2HgPh$ (lactate), $AcOHgPh$, $EtCO_2HgPh$, $PrCO_2HgPh$, $C_5H_{11}CO_2HgPh$ (caproate), $C_{17}H_{35}CO_2HgPh$ (stearate) and $BzOHgPh$. The probable scheme of the reaction is: $RHgPh \rightleftarrows R—$ and $PhHg—$ the free radicals react with the alc.: $2\ R— + EtOH \rightarrow 2\ RH + AcH$; $2\ PhHg— + EtOH \rightarrow 2\ Hg + 2\ C_6H_6 + AcH$. The acid (RH), formed in the reaction, reacts with the alc. to give the Et ester: $C_{17}H_{35}CO_2H + EtOH \rightarrow H_2O + C_{17}H_{35}CO_2Et$. Chas. Blanc

Condensation of arsenic chloride with dialkyl aromatic amines. Phuldeo S. Varma, K. S. V. Raman and K. M. Yashoda. *J. Indian Chem. Soc.* **16**, 515–18(1939).—$AsCl_3$ (I) condenses with dialkyl aromatic amines to form *p*-dialkylaminophenylarsenious chlorides. The reaction with $PhNMe_2$ proceeds further with the formation of $(Me_2NC_6H_4)_3As$. The reaction has been extended to $PhNMeEt$ (II), $\alpha\text{-}C_{10}H_7NMe_2$ (III), $m\text{-}MeC_6H_4NMe_2$ (IV) and $p\text{-}MeC_6H_4NMe_2$ (V). A mixt. of 15 g. II and 25 g. I was heated at 100° for 2 hrs. and the reaction product was poured into cold H_2O. After neutralization with 10% NaOH, filtration from solids (VI) and acidification, the product was pptd. with Na_2CO_3. The crude oxide was purified by dissolving in dil. HCl and repptg. with Na_2CO_3, yielding *p-methylethylaminophenylarsenious oxide*, $C_9H_{12}AsNO$, m. 74–5°; *sulfide*, m. 157°; *chloride-HCl*, m. 99°, converted by Na_2CO_3 to the oxide; *bromide-HBr*, m. 143°; *iodide-HI*, light yellow unstable powder; *arsonic acid*, $C_9H_{14}AsNO_3$, m. above 250°. VI was freed from unreacted II by treatment with petr. ether and was recrystd. from $CHCl_3$, giving *tris(p-methylethylaminophenyl)arsine*, $C_{27}H_{36}AsN_3$, m. 206°, which was also produced in better yield (3 g.) by the reaction of equimol. amts. of II (5 g.) and I (7 g.). Similarly the reaction of 10 g. III and 26 g. I and isolation with Na_2CO_3, gave 7 g. of white, amorphous *4-dimethylamino-1-naphthylarsenious oxide*, $C_{12}H_{12}AsNO$, m. 98–100°; *sulfide*, m. 144°; *chloride-HCl*, m. 110–2°; *bromide-HBr*, sol. in org. solvents except ether; *iodide-HI*, m. 119–20°, pale yellow powder; *tris(4-dimethylamino-1-naphthyl)arsine*, $C_{36}H_{36}AsN_3$, m. 148°, formed as a by-product. Similarly *4-dimethylamino-2-methylphenylarsenious oxide*, $C_9H_{12}AsNO$, m. 108° (*sulfide*, m. 137°; *arsonic acid*, m. above 250°), and *tris(4-dimethylamino-2-methylphenyl)arsine*, $C_{27}H_{36}AsN_3$, m. 98°, were prepd. from IV and I. V gave the corresponding *2-dimethylamino-5-methylphenylarsenious oxide*, m. 63–5°; *sulfide*, m. 68°; *arsonic acid*, m. above 250°. C. R. Addinall

Autometalation with *m*-tolylsodium. Henry Gilman and H. A. Pacevitz. *J. Am. Chem. Soc.* **62**, 673–4(1940). —$m\text{-}ClC_6H_4Me$ and Na in petr. ether (b. 85–100°) first give $m\text{-}MeC_6H_4Na$, as evidenced by the formation of $m\text{-}MeC_6H_4CO_2H$ on carbonation. On refluxing the mixt., the $m\text{-}MeC_6H_4Na$ is converted to $PhCH_2Na$. It is difficult to account for the migration on the basis of an allylic rearrangement. C. J. West

Conversion of arylbismuth halides to triarylbismuth compounds. Henry Gilman and H. L. Yablunky. *J. Am. Chem. Soc.* **62**, 665–6(1940).—Ph_2BiCl (4 g.), added to 2 g. $N_2H_4.H_2O$ in 60 cc. abs. EtOH (reaction occurs immediately) and the mixt. stirred for 1 hr., heated to boiling, filtered and the insol. material again extd. with EtOH, the EtOH poured into 400 cc. H_2O and the ppt. extd. with Et_2O, gives 93.5% Ph_3Bi (I). Ph_3BiCl_2 (2.56 g.) in 60 cc. 95% EtOH and 2 g. $N_2H_4.H_2O$ give 95.4% I which ppts. in 0.5 min.; the mixt. is stirred for 1 hr., poured into 300 cc. H_2O and the I is extd. with Et_2O. $PhBiBr_2$ gives 81.5% I, Ph_2BiBr_3 100% I and Ph_3BiF_2 97.8% I. $(o\text{-}MeC_6H_4)_3BiCl_2$ and $(o\text{-}MeC_6H_4)_3BiBr_2$ give 99 and 100% $(o\text{-}MeC_6H_4)_3Bi$; $(p\text{-}MeC_6H_4)_3BiCl_2$ gives 100% of $(p\text{-}MeC_6H_4)_3Bi$. $(p\text{-}ClC_6H_4)_3BiCl_2$ gives 78% of $(p\text{-}ClC_6H_4)_3Bi$; this is the only reaction in which apparent decompn. occurs. $Ph_2(\alpha\text{-}C_{10}H_7)BiCl_2$ gives 96.2% of $Ph_2(\alpha\text{-}C_{10}H_7)Bi$. C. J. West

Behavior of acyl derivatives of aminobenzenesulfonamide in the presence of hydrochloric acid. Antonio Mossini. *Boll. soc. ital. biol. sper.* **14**, 387–9(1939).—N^4-Acyl derivs. of *p*-aminobenzenesulfonamide were partially sapond. (up to 47%) in the presence of HCl at body temp. for 3 hrs. Helen Lee Gruehl

Some fluorine and chlorine derivatives of sulfanilamidobenzenesulfonic acids. C. M. Suter and Arthur W. Weston. *J. Am. Chem. Soc.* **62**, 604–6(1940); cf. *C. A.* **33**, 1686[9], 8593[2], 8588[5].—$p\text{-}FC_6H_4NHAc$ and 100% H_2SO_4, heated until the solid melted and kept at this temp. until AcOH is no longer evolved, then heated at 170–80° for 2 hrs., give 64% of *4-fluoroaniline-2-sulfonic acid* (I), decomps. above 310°; *4-Cl analog* (II), decomps. above 325° (49% yield). I (0.5 g.) with excess 5% aq. Br gives 0.6 g. *2,6-dibromo-4-fluoroaniline*, m. 63–4°; II gives $4,2,6\text{-}ClBr_2C_6H_2NH_2$, m. 94.5–5.5°. $4\text{-}FC_6H_4NHAc$ and 15% oleum, heated to 140–5°, give 63% of *4-fluoroaniline-3-sulfonic acid* (III), decomps. above 310°; *4-Cl analog* (IV), decomps. above 310° (30–4% yield). Bromination of III in H_2O gives no ppt.; evapn. of the soln. gives the *compd.* $C_6H_4O_3SNBr_2F$, which crystallizes from concd. HCl; the *analog* from IV decomps. above 310°; the compd. is hygroscopic. $p\text{-}FC_6H_4NH_2$ (0.08 mol.), 0.015 mol. Na_2CO_3 and 60 ml. H_2O, treated with 0.08 mol. of $p\text{-}AcNHC_6H_4SO_2Cl$ and 30% NaOH to keep the pH at about

10, stirred 30 min., 8 g. solid NaOH added and the mixt. refluxed 90 min., give 47% of *N-sulfanilyl-4-fluoroaniline* (V), m. 163–4°. The above sulfonic acids give the following: *2-sulfanilamido-5-fluorobenzenesulfonic acid*, decomps. 285°, 14% yield; *5-sulfanilamido-2-fluoro isomer*, with 1 mol. H_2O decomps. 260°, 42% yield; *2-sulfanilamido-5-chlorobenzenesulfonic acid*, with 1 mol. H_2O, decomps. 300°, 20% yield; *5-sulfanilamido-2-chloro isomer*, decomps. 310°, 57% yield. These acids did not exhibit therapeutic action against streptococcus and Type I pneumococcus infections in white mice. V showed a slight effect against streptococcus infections. C. J. West

Synthesis of sulfonyl chlorides by chlorination of sulfur compounds. Treat B. Johnson. *Proc. Natl. Acad. Sci. U. S.* **25**, 448–52 (1939).—In addn. to work previously reported by Johnson and his coworkers on the chlorination of S compds. (*C. A.* **32**, 1176, 5777[1], 6248[8]; **33**, 1682[4]), it is found that *S*-benzyl-*N,N,N'*-trimethylisothiourea-HCl reacts smoothly with Cl (Cl water) to yield benzylsulfonyl chloride and trimethylurea, m. 74–5°. Rachel Brown

The esters of sulfurous, chlorosulfinic and chlorosulfonic acids. III. Wm. Gerrard. *J. Chem. Soc.* **1940**, 218–30; cf. *C. A.* **33**, 2483[6].—The decompn. of PhOSOCl (I) and certain typical aliphatic chlorosulfinates in the presence of C_5H_5N, quinoline (II), $PhNMe_2$ and their HCl salts has been examd. with special reference to the fate of the base or its HCl salt. It is shown that, not only is the decompn. mechanism in the presence of the base quite different from that in the presence of the HCl salt but there is a fundamental difference between the modes of decompn. of the aromatic and the aliphatic chlorosulfinates. I (23.75 g.) in 30 cc. dry ether and 10.7 g. C_5H_5N in 20 cc. ether at −10° show no reaction after 3 days at room temp.; addn. of 12.2 g. PhOH in 20 cc. ether at −10° ppts. 9.2 g. of C_5H_5N.HCl (IIA) and gives 18.5 g. of Ph_2SO_3, showing the presence of I in the reaction mixt. I reacts explosively with C_5H_5N or II at 122° and is decompd. vigorously by their HCl salts at 98° and 100°, resp. Although I reacts explosively within 1 min. of being mixed with $PhNMe_2$, no such reaction occurs when it is heated in the presence of the HCl salt, slow evolution of gas occurring at about 50°. Thick oils or brown solids are produced in these reactions which will be characterized later. $SOCl_2$ (0.5 mol.) in 50 cc. ether, added slowly to 1 mol. PhOH in 200 cc. ether and 1 mol. of C_5H_5N at −5°, causes the pptn. of 153 g. of IIA and gives 91% of Ph_2SO_3. Using 1 mol. of II, 15.9 g. of IIA is pptd. and 9.6 g. of Ph_2SO_3 may be isolated. I (17.6 g.) and 5.5 g. of 100% HCO_2H react at room temp., giving 3.45 g. of HCl, 5.77 g. of SO_2 and 508 cc. CO; distn. after 4 hrs. gives 7.8 g. b_{18} 77–85° and 3.6 g. of a sirupy residue; the distillate contains 84% of the formate. I (17.6 g.), added slowly to 15.6 g. of *l*-menthol and 8 g. C_5H_5N in ether at −5°, gives a ppt. of 11.4 g. of IIA and 3.8 g. of *Ph menthyl sulfite*, b_{2-3} 156–60°, $[\alpha]_D^{25}$ 10.61°. Ph_2SO_3 and $SOCl_2$ after 48 hrs. give 10% of I. BuOSOCl (III) (0.1 mol.), mixed with C_5H_5N at −10° and kept at 0°, gives a red oil within a few min., the temp. rising to 10°; treatment with dil. H_2SO_4 gives a lower aq. layer contg. the butylpyridinium ion, 0.1 mol. SO_2, 1.6 g. Cl ion and 60% of C_5H_5N; the upper layer yields 42% of BuCl. II and III (0.1 mol. of each) at −10° give 4 g. SO_2, 8.3 g. II, 60% BuCl and 8.8 g. of an oil, which gives *butylquinolinium chloroplatinate*, m. 223–4° (decompn.). Et α-chlorosulfinoxypropionate (IV) and C_5H_5N react gradually at 0°; after removal of the cooling medium, the mixt. becomes quite hot in 4–5 min., forming a dark red liquid and emitting very little SO_2 and HCl; addn. of ether gives 11.3 g. of a dark red oil, from which H_2O exts. 3.74 g. SO_2, 4.5 g. C_5H_5N and 55% of $MeCHClCO_2Et$ (V), but no Cl ion. II and IV evolve SO_2 when heated to 55°; 75% of V is formed; *α-carbethoxyethylquinolinium chloroplatinate*, m. 170–1°. IV and II in ether at 16° give about the same products as without ether. MeOSOCl reacts rapidly with II in ether at −10°; EtOSOCl reacts less rapidly, giving *ethylquinolinium chlorosulfinate*, a solid tending to change to a red sticky mass; other chlorosulfinates give oils. IV and $PhNMe_2$, mixed at −10°, become hot in 3 min. after the cooling bath is removed, SO_2 being evolved; the residue gives 50% of V and a trace of α-ethoxycarbethoxyl sulfite (VI); III and $PhNMe_2$ react vigorously at −10°, SO_2 and BuCl being evolved; BuCl and Bu_2SO_3 were isolated after addn. of dil. HCl. In ether IV and $PhNMe_2$ give V and VI; III yields BuCl and Bu_2SO_3; Me, Et, Pr, iso-Bu and Am chlorosulfinates react with $PhNMe_2$ in ether below room temp. IV with IIA, gently heated to 60°, begins to evolve SO_2 at 39° and gives a nearly quant. yield of IIA and V; $PhNMe_2$.HCl causes a slow evolution of SO_2 up to 97° (heating during 1 hr.) and gives a quant. yield of V. Et lactate and C_5H_5N (2 mols. of each) in ether at −10°, treated dropwise with 1 mol. of $SOCl_2$, give a quant. yield of IIA and 90% of VI; subsequent heating of the mixt. decreases the yield of VI to 25%; II and $PhNMe_2$ give similar results. BuOH gives Bu_2SO_3. III (39.1 g.), added slowly to a mixt. of *l*-menthol and C_5H_5N in ether, gives 56 g. *l-menthyl Bu sulfite*, b_1 98–9°, $[\alpha]_D^{18}$ −32.5°, d_4^{17} 1.0025. IV and BuOH give 80% of *α-carbethoxyethyl Bu sulfite*, b_{19} 141–2°. Addn. of 9 g. $SOCl_2$ in 10 cc. ether to 19.5 g. β-octanol (VII) and 12 g. C_5H_5N in 50 cc. ether at −10° causes the pptn. of 16.7 g. IIA; half of the filtrate treated with 4.5 g. $SOCl_2$ and after 18 hrs. with 6 g. C_5H_5N, gives 6 g. of a dark red oil contg. a β-octylpyridinium compd. and 43% of β-octyl chloride (VIII); washing the other half of the above filtrate gives 7.2 g. of β-octyl sulfite. VII (39 g.) in an equal vol. of ether, added slowly to 60 g. $SOCl_2$ in ether at −10°, gives 67.9 g. (calcd. 63.6 g.) of *β-octyl chlorosulfinate* (IX), pale yellow; with ice 15 g. IX gives 7.5 g. VII; 21.2 g. IX gives with C_5H_5N 81% of VIII; IX with HCO_2H gives SO_2 and HCl in the ratio of 1 1, CO_2 and probably β-octyl formate. Et mandelate (X) and C_5H_5N in ether, treated with $SOCl_2$ in ether, give a ppt. of IIA; there is no apparent reaction when 3 g. $SOCl_2$ is added to the ether filtrate but after 12 hrs. addn. of C_5H_5N ppts. an oil not completely sol. in H_2O; the aq soln. gives *α-carbethoxybenzylpyridinium ferrocyanide* (XI), yellow, and the ether soln. gives 36% of $PhCHClCO_2Et$ (XII). X (18 g.), added dropwise to 20 g. $SOCl_2$ in ether at −10° and allowed to stand 1 hr. at 16°, gives 26.8 g. of *α-carbethoxybenzyl chlorosulfinate* (XIII); reaction of XIII with C_5H_5N in ether at −10° and treatment with H_2O gives XI and 46% of XII; with HCO_2H XIII gives SO_2 and HCl in the ratio of 1·1 and CO; with ice XIII yields X and XII. PhMeCHOH (XIV) and $SOCl_2$ give *α-phenylethyl chlorosulfinate*, pale yellow; C_5H_5N yields $PhCHClMe$; $SOCl_2$, added to XIV and C_5H_5N in ether, give a ppt. of IIA; addn. of $SOCl_2$ to the ether filtrate produced no apparent effect but addn. of H_2O or C_5H_5N gives $PhCHClMe$. Iso-PrOH and *sec*-BuOH give the corresponding chlorosulfinates with $SOCl_2$ in 75–80% yields; *isopropylpyridinium ferrocyanide; sec-Bu analog*, yellow. Addn. of PCl_5 to BuOH, VII or X and C_5H_5N at −10° gives a nearly quant. ppt. of IIA; further addn. of PCl_5 produces no apparent effect. $POCl_3$ gives similar results but the pptn. of IIA is slower. Passing Cl into 75.5 g. of VI at 0° for 6 hrs. gives 53.1 g. V and 43 g. *Et α-chlorosulfonoxypropionate* (XV), b_2 90–2°; this was also prepd. from Et lactate and SO_2Cl_2 in 65% yield. XV and C_5H_5N in ether at −10° gives $C_5H_5N.SO_3$ and 85% of V. II and XV yield *quinoline-SO_3* (if the washing with ice water is not rapidly carried out, the sulfate is formed) and V. Addn. of $COCl_2$ in PhMe to Et lactate and C_5H_5N in PhMe at −10° gives IIA and 90% of *α-carbethoxyethyl carbonate*, b_1 110–10.5°, $d_4^{16.5}$ 1.1280, d_4^{27} 1.1080, n_D^{15} 1.4280. No pptn. occurs when $PhOSO_2Cl$ (XV) is added to C_5H_5N or II in ether even when BuOH is added to the resulting mixt. In the absence of ether these bases gave no indication of a reaction when added to XV. $PhNMe_2$ appears to react and gives a vivid deep blue liquid, slowly in the cold, rapidly on heating on a water bath; the oil is insol. in H_2O but is sol. in EtOH, giving rise to a blue soln. which exhibits a "universal indicator" effect, violet (alkali) → yellow (acid). A general theory is submitted to account for the exptl. results of other workers in this field; 1 section discusses the Walden inversion and $SOCl_2$.

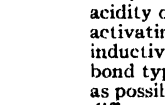
C. J. West

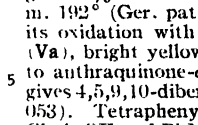
Sulfanilamide derivatives. VI. Substituted *N*[1]-ali-

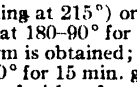
phatic sulfanilamides. M. L. Crossley, E. H. Northey and M. E. Hultquist. *J. Am. Chem. Soc.* **62**, 532–4 (1940); cf. *C. A.* **34**, 2379[1].—The following derivs. were prepd. by the general procedure used previously (*C. A.* **32**, 8381[6]) except in the case of the amino-acid ester derivs. The *N*-sulfanilylamino acids were first prepd. and were esterified by boiling with the corresponding alc. and HCl. *N*[1]-*Octylsulfanilamide*, m. 114–19.5°; *dodecyl homolog*, m. 118–24°; *octadecyl homolog*, m. 127–30°; *9-octadecenyl analog*, m. 118–22.5°; *1,2-bis(sulfanilamido)-ethane*, m. 229.4–31.2° (cryst. as the Na salt from H_2O); *1,2-bis(N*[4]*-sulfanilylsulfanilamido)ethane*, m. above 118° (decompn.); *N*[1],*N*[1]*-bis(2-sulfanilamidoethyl)sulfanilamide-3HCl*, m. 241.5–4°; *N*[1]*-methyl-N*[1]*-2-hydroxyethylsulfanilamide*, m. 124.5–6.3°; *2-methyl-2-sulfanilamido-1-propanol*, m. 154–5.8°; *2-methyl-2-sulfanilamido-1,3-propanediol*, m. 131.8–4°; *1,3-bis(sulfanilamido)-2-propanol*, m. 184.2–6.5°; *N*[1]*-2-hydroxyethyl-N*[1]*-(2-sulfanilamidoethyl)sulfanilamide*, m. 163–4.5°; *N*[1],*N*[1]*-difurfurylsulfanilamide*, m. 134–6.5°; *N-(2-sulfanilamidoethyl)-morpholine*, m. 98–100.4°; *Et N-sulfanilylglycinate*, m. 90.4 2°; *di-Bu N-sulfanilylglutamate-HCl*, m. 138.4 41.6°. $4\text{-}O_2NC_6H_4SO_2Cl$ and excess aq. $2\text{-}HOC_2H_4NH_2$ give *N*-2-hydroxyethyl-4-nitrobenzenesulfonamide, m. 126–7°; dodecanoyl chloride in C_5H_5N at 90–100° gives 4-nitrobenzenesulfonamidoethyl dodecanoate, m. 72–3.5°; reduction with Fe and HCl in PhMe-H_2O gives *2-sulfanilamidoethyl dodecanoate*, m. 63.4–4.8°. The available pharmacol. data indicate that these compds. as a class are less effective than sulfanilamide against infections by β-hemolytic streptococci in mice. C. J. West

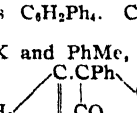
Tin derivative of dithiopyrocatechol. Harold P. Brown and James A. Austin. *J. Am. Chem. Soc.* **62**, 673 (1940). —In the prepn. of dithiopyrocatechol (I) from $o\text{-}C_6H_4(SO_2Cl)_2$ by reduction with Sn and HCl, Guha and Chackladar (*C. A.* 20, 1797) obtained a red solid which they considered to be the lactone of benzene-1-thiol-2-sulfonic acid. It is shown that this red compd. is probably $(o\text{-}C_6H_4S:)_2Sn$. Redistn. of the distillate contg. the red compd. from concd. HCl yields pure I. The red compd. on standing in concd. HCl gives I. The completeness of the reaction of I with $SnCl_2$ or $SnCl_4$ suggests the possible application of I to the qual. and perhaps quant. detn. of Sn and certain other elements; Sb, Zn, Fe^{+++}, Pb and Tl react with I. C. J. West

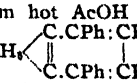
Action of nitrosylsulfuric acid on *m*-fluorophenol. New red *o*-quinonimine. Herbert H. Hodgson and Donald E. Nicholson. *J. Chem. Soc.* **1940**, 205–7; cf. *C. A.* **34**, 738[3].—$m\text{-}FC_6H_4OH$ (2 g.) in 20 cc. AcOH, added below 20° to 2 g. $NaNO_2$ in 10 cc. concd. H_2SO_4 (previously heated to 70°) and, after 10 min. at 0°, poured onto ice, give a yellow-brown ppt. (a mixt. of a red and a green compd.); extn. with boiling petr. ether (80–100°) removes a very small quantity of *3-fluoro-4-nitrosophenol* or *3-fluorobenzoquinone 4-oxime* (I), green, m. 158°; the residue (1.8 g.) seps. from EtOH in dark red plates which do not m. below 300°; this is *4,2′-difluoro-4′-hydroxy-o-benzoquinone-1-phenylimine* (II). II evolves NH_3 when boiled with NaOH. II is compared with the reaction product (*m,m′*-difluoro-*o*-indophenol (III)) of $m\text{-}FC_6H_4OH$ with aq. HNO_2. II is more sol. in aq. alkali hydroxides and carbonates and less sol. in AcOH. Reductive acetylation of II gives *N-acetyl-4,2′-difluoro-2,4′-diacetoxydiphenylamine*, very pale yellow, no m. p.; concd. H_2SO_4 gives a blue-green color; III gives *N-acetyl-4,4′-difluoro-2,2′-diacetoxydiphenylamine*, very pale yellow, m. 175°; concd. H_2SO_4 gives a violet color. II and $PhNH_2$ in AcOH give *4,2′-difluoro-4′-hydroxy-o-benzoquinonebisphenylimine*, maroon, m. 200°; III gives *4,4′-difluoro-2′-hydroxy-o-benzoquinonebisphenylimine*, deep red, m. 175°. II, boiled with aq. $KMnO_4$ and H_2SO_4, gives a steam-volatile *p*-benzoquinone but III gives a non-steam-volatile *o*-benzoquinone. Reduction of II in glacial AcOH with Zn gives a colorless leuco compd. which is reoxidized in the air in HCl to reform II, whereas III gives a blue oxazine. Oxidation of I with $K_3Fe(CN)_6$ gives $3,4\text{-}F(O_2N)C_6H_3OH$. It is suggested that $m\text{-}FC_6H_4OH$ is first nitrosated in position 4 (and in a small degree nitrated in position 6), followed by rapid condensation of the NO compd. with unchanged $m\text{-}FC_6H_4OH$ to give II. C. J. West





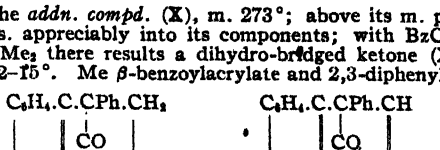






Hydrogen fluoride as a condensing agent. X. Rearrangements. J. H. Simons, S. Archer and D. I. Randall. *J. Am. Chem. Soc.* **62**, 485–6 (1940); cf. *C. A.* **34**, 232[6].—PhOH and *tert*-BuPh with HF at 0° for 13 hrs. give C_6H_6 and about 10% of $p\text{-}tert\text{-}BuC_6H_4OH$. $Ph_2C{:}NOH$ in AcOH or ether with HF gives about 72% of $BzNH_2$; PCl_5 gives a nearly quant. yield. AcOPh and HF at room temp. give no appreciable yield of rearranged product; heating in a sealed vessel for 24 hrs. at 100° gives $p\text{-}HOC_6H_4Ac$, although the reaction is not smooth and the yield is poor. $p\text{-}MeC_6H_4OSO_2Ph$ and HF in ligroin, heated in a Cu bomb for 14 hrs. at 100°, give 10% of $4,2\text{-}Me(HO)C_6H_3SO_2Ph$ (I). $p\text{-}MeC_6H_4OMe$ and $PhSO_2Cl$ with $AlCl_3$ in CS_2, refluxed 5 hrs., give 71% of *2-methoxy-4-methyldiphenyl sulfone* (II), m. 137–8°. Heating 3 g. II and 6 g. $AlCl_3$ at 140–50° for 2 hrs. gives 95% I, m. 137–8°. C. J. West

Composition of laccol. G. Bertrand, H. J. Backer and N. H. Haack. *Bull. soc. chim.* **6**, 1670–6 (1939).—Bertrand and Brooks (*C. A.* **27**, 4534) obtained laccol (I), m. 23°, in the cryst. state. I, initially isolated by Bertrand in 1894, was investigated by Majima (*C. A.* **16**, 2331) who obtained it as a thick, brown liquid (to which he attributed the formula $2,3\text{-}(HO)_2C_6H_3C_{17}H_{31}$) and who prepd. the tetrahydrolaccol (II) and its di-Me ether (III). Backer and Haack (*C. A.* **32**, 4965[2]), continuing their work on the toxic principles of the fruits of Renghas, have isolated a product, of which the hydrogenation product, m. 63°, was identified as 2,3-dihydroxyheptadecylbenzene (III). Com. cetyl alc. (1 kg.) and 600 g. AcOH were heated together for 2 hrs. at 100° with dry HCl. The heating was continued for 4 hrs. and the reaction product was washed with Na_2CO_3 and H_2O. Fractional distn. gave 388 g. of pure $C_{16}H_{33}OAc$, b_6 176–7°, sapond. by alc. KOH to yield 300 g. of pure $C_{16}H_{33}OH$, m. 45–6°, b_{15} 189–90°, converted by refluxing with HBr and H_2SO_4 to 200 g. of $C_{16}H_{33}Br$ (IV), b_4 169–70°. Methylation of 152 g. $2,3\text{-}HO(MeO)C_6H_3CHO$, m. 43.5–4.5°, with Me_2SO_4 in NaOH gave 85% (139 g.) of $2,3\text{-}(MeO)_2C_6H_3CHO$ (V), m. 51–2°, b_{16} 139.5–40°. A mixt. of 46 g. IV in 50 cc. anhyd. ether and 3.65 g. Mg in 50 cc. anhyd. ether was gently warmed in the presence of a trace of I. The cooled soln. was treated with 16.6 g. of V in 25 cc. ether. The next day the product was dild. with H_2O and 200 cc. of 2 *N* H_2SO_4. The ether ext. was washed, dried and evapd. and the residue was dissolved in 100 cc. of hot alc. On cooling, bicetyl, $C_{32}H_{66}$, m. 68–70°, crystd. out. The filtered soln. was concd. to 50 cc. and yielded 50% (19.5 g.) of *2,3-dimethoxyphenylhexadecylmethanol* (VI), $C_{25}H_{44}O_3$, m. 55–6°. Heating 17.7 g. VI at 210° with 0.5 g. $KHSO_4$ and recrystg. the product from alc. and petr. ether gave 62% (10.6 g.) of *2,3-dimethoxyheptadecenylbenzene* (VII), $C_{25}H_{42}O_2$, m. 47.0–7.5°, b_2 235–8°. Reduction of 9.4 g. VII in 100 cc. AcOH in the presence of 0.5 g. PtO_2 gave 84% (8 g.) of 2,3-dimethoxyheptadecylbenzene (VIII), $C_{25}H_{44}O_2$, m. 44.5–5.0° (corresponding to Majima's tetrahydrolaccol di-Me ether, m. 43–4°). Demethylation of 3.77 g. VIII by heating in a sealed tube for 10 hrs. at 180° with 10 cc. HI (d. 1.7), 5 cc. AcOH, a crystal of PhOH and a little red P gave 1.7 g. (50%) of III, $C_{23}H_{40}O_2$, m. 63–4°, identical with II as prepd. by B. and B. Acetylation of III with Ac_2O gave the *diacetate*, $C_{27}H_{44}O_4$, m. 57.8–8.3°, identical with the diacetyltetrahydrolaccol of B. and B. I has the formula attributed to it by M. on the basis of an impure oil which gave other results on analysis than those obtained from cryst. I. C. R. Addinall



The steric effect of the nitro group on the orientation of a third substituent in *m*-nitrophenol. D. R. Mehta and P. Ramaswami Ayyar. *J. Univ. Bombay* **8**, Pt. 3, 176–83 (1939).—The orienting effect of the NO_2 group in $m\text{-}O_2NC_6H_4OH$ (I) in the reaction with CH_2O (II), $CHCl_3$ (III) and NaOH, and $Hg(OAc)_2$ is studied. When 5 g. I is refluxed with 25 cc. concd. HCl and 4 g. of a 40% soln. of II at 130–40° for 2–3 hrs., the supernatant clear soln. poured off and the residue, after washing with 2 *N* NaOH,

crystd. from EtOH, 0.85 g. of the methylene ether (IV)  , m. 77°, of a nitrohydroxybenzyl alcohol is obtained. Structure of IV is proved by its oxidation with Cr_2O_3 in AcOH whereby 6-nitrosalicylic acid (V), m. 166–7°, is formed. Warming of 0.231 g. IV with 30 cc. of a soln. of 3 g. phloroglucinol in 60 cc. H_2SO_4 and 200 cc. H_2O at 80–90° for 2 hrs. gives in almost quant. yield a $C_7H_7O_2$-phloroglucinol condensation product. The formation of IV shows that the phenolic OH group has a predominating influence in directing the entrance of the oxymethyl group into the C_6H_6 ring. When to a soln. of 5 g. I in 35 cc. H_2O contg. 6.5 g. NaOH, 7 cc. III is added and the mixt. refluxed on a water bath for 1 hr., the excess of III removed, the residue acidified with dild. H_2SO_4 and steam-distd., there comes over a mixt. of I and 6-nitrosalicylaldehyde (VI), m. 50 1°, which are sepd. by extn. with $NaHSO_3$ soln. Oxidation of VI with $KMnO_4$ gives V. When a mixt. of 5 g. I and 11.5 g. $Hg(OAc)_2$ in 100 cc. EtOH is refluxed for 0.5 hr., the soln. poured off from the residue and cooled, *acetoxymercurinitrophenol* (VII), m. 207–8°, crystallizes. Treatment of VII with NaCl yields the *chloromercuri deriv.* m. 179–80°. The latter, when treated with 1.8 *N* Br in KBr, yields 2,4,6-tribromo-3-nitrophenol, m. 87–8°. An attempt to prep. the mono-Br deriv. failed. This result shows that the AcOHg group has entered the C_6H_6 ring in either the 1-, 4- or 6-position, indicating again that the OH group chiefly directs the orientation of the AcOHg group. F. E. Brauns

Aromatic stabilized double bonds. Mills-Nixon problem. Richard T. Arnold and Robert L. Evans. *J. Am Chem. Soc.* **62**, 556–8(1940); cf. *C. A.* **33**, 8598⁸.—In the light of recent structural studies on C_2H_4 and C_2Me_4, some of the original assumptions of the Mills-Nixon postulate are questionable. Values for pK in EtOH-H_2O (50% by wt.) and the temp. are: 2-$O_2NC_6H_4OH$ 8.20, 29°; 4,5,2-$Me_2(O_2N)C_6H_2OH$ (I) 8.81, 28°; 8.90, 37°; 5-hydroxy-6-nitrohydrindene (II) 8.96, 37°; 6-hydroxy-7-nitrotetralin (III) 9.05, 37°; 4-methyl-2-nitrophenol (IV) 8.57, 28°; 5,2-$Me(O_2N)C_6H_3OH$ (V) 8.43, 28°. The acidity of the HO group depends on 4 factors: the type of activating group present, strength of the chelate ring, the inductive effect of all the dipoles present and the C—C bond type between the HO and activating group. As far as possible the 1st 3 factors have been held const. in I–III; differences in the dissocn. consts. for these compds. must then indicate a dissimilarity in bond type. Actually the acidities of I–III are almost identical. A study of any interaction (ortho effect) between the 2 Me groups in I has been made by detns. on IV and V. Such interactions seem to be active but appear to be const. in I–III. This has been recognized in dipole-moment studies. C. J. W.

Addition reactions of vinyl phenyl ketone. VI. The diene synthesis. C. F. H. Allen, A. C. Bell, Alan Bell and James Van Allan. *J. Am. Chem. Soc.* **62**, 656–64 (1940); cf. *C. A.* **29**, 5835².—The original purpose of this work was the synthesis of 3,4-$Ph_2C_6H_3Bz$ (I), previously obtained as a degradation product of a dimeric diphenylcyclopentadienone (*C. A.* **27**, 5071). CH_2:CHBz (II) adds readily to many substances contg. a conjugated system of double bonds and, in general, the addn. products have the expected properties. The reaction is most useful with unsatd. ketones; it is less satisfactory with hydrocarbons and fails with furans. 2,3-Diphenyl-1,3-butadiene (11 g.), 9.2 g. of $BzCH_2CH_2Br$, 5.4 g. AcONa and 75 cc. xylene, refluxed 60 hrs., give 8.5 g. of *3,4-diphenyltetrahydrobenzophenone* (III), m. 83°; *2,4-dinitrophenylhydrazone*, orange, m. 203°; dehydrogenation of 7.8 g. III in 15 cc. $CHCl_3$ with 8 g. of Br in 20 cc. $CHCl_3$ gives 97% of I, m. 133° (*2,4-dinitrophenylhydrazone*, orange, m. 248°). $NaNH_2$ and I in cymene give 70% of *o*-$C_6H_4Ph_2$ and 7% of 3,4-$Ph_2C_6H_3CO_2H$. 1,4-Diphenylbutadiene does not add II nearly as readily as the 2,3-isomer and a cryst. addn. product was not obtained; refluxing for 48 hrs. produces about 30% addn.; dehydrogenation by heating with S at 200° for 2 hrs. gives *2,5-diphenylbenzophenone*, m. 130°; $NaNH_2$ gives *p*-$C_6H_4Ph_2$, showing that a 6-membered ring had been formed in the addn. 2,3-Dimethylbutadiene and $BzCH_2CH_2Br$ (heating for 24 hrs.) give *3,4-dimethyltetrahydrobenzophenone* (IV), b_6 163–5° (*2,4-dinitrophenylhydrazone*, orange-yellow, m. 152°); there is no reaction of IV with Br in the cold; on warming HBr is split off and a *dibromide*, m. 132°, results. Dehydrogenation of IV with S at 190–230° gives 3,4-$Me_2C_6H_3Bz$, m. 45° (*2,4-dinitrophenylhydrazone*, m. 252°). 1-Phenyl-4-methylbutadiene and $BzCH_2CH_2Cl$ with AcOK in $C_6H_3Cl_3$, refluxed 8 hrs., give 5 g. of *benzoylmethylphenylcyclohexene*, MeCH.CH:CH.CHPh.CH_2.-CHBz or MeCH.CH:CH.CHPh.CHBz.CH_2, b_1 157–9°, m. 61°; *dibromide*, m. 125°. Cyclopentadiene and $BzCH_2CH_2Cl$ with AcOK in PhMe, heated at 95–100° for 30 hrs., give *1-benzoyl-1,2,3,6-tetrahydro-3,6-methanobenzene*,  , b_3 122–4°, n_D^{25} 1.5648 (*semicarbazone*, m. 178–80°). The liquid product from isoprene decompd. on distn., but a ketonic *deriv.*, b_2 120 2°, was prepd. from 1 fraction, whose *2,4-dinitrophenylhydrazone*, $C_{30}H_{20}O_4N_8$, m. 137°. Phellandrene gives a hopeless mixt. (37% of an oil, b_2 183–5°) which decolorizes Br instantly with evolution of HBr. Cyclohexadiene gives only *β-ethoxypropiophenone* (V). Methyleneanthrone (5.2 g.), $BzCH_2CH_2Cl$ (6 g.) and AcOK in $PhNO_2$, refluxed 2.5 hrs. at 180–90°, give 84% of *bz*-1-benzoylbenzanthrone, brownish yellow, m. 192° (Ger. pat. 420,412); the structure follows from its oxidation with CrO_3 to *α-benzoylformylanthraquinone* (Va), bright yellow, m. 174°, which is cleaved by Na_2O_2 to anthraquinone-α-carboxylic acid; with NaCl-$AlCl_3$ it gives 4,5,9,10-dibenzopyrene-3,8-quinone (Ger. pat. 412,053). Tetraphenylcyclopentadienone (VI), $BzCH_2CH_2Cl$, AcOK and PhMe, refluxed 3 hrs., give a nearly quant. yield of *3,4,5,6-tetraphenyl-7-keto-1-benzoyl-1,2,3,6-tetrahydro-1,6-methanobenzene* (VII),  , 210° (gas evolution); it is recovered unchanged after boiling with $KMnO_4$ in Me_2CO, glacial AcOH and SeO_2 or H_2O_2; Br in $CHCl_3$ and CrO_3 in AcOH slowly attack VII, giving ill-defined products. VII also results when II and VI in C_6H_6 are refluxed for 2 hrs. or when the components are heated in the absence of a solvent at 130°; it is also obtained when the $BzCH_2CH_2Cl$ is replaced by an equiv. amt. of $BzCH_2CH_2NMe_2$ (after 24 hrs. the yield is 25%). Pyrolysis of VII or carrying out the addn. reaction in $C_6H_3Cl_3$ or $PhNO_2$ gives *dihydro-3,4,5,6-tetraphenylbenzophenones* (VIII), CPh:CPh.CH_2.CHBz.CPh:CPh or CHPh.CH:CBz.CHPh.CPh.CPh, pale yellow, m. 177° (from VII on heating at 215°) or m. 158–9° (from the reaction in $C_6H_3Cl_3$ at 180–90° for 3 hrs.); with $PhNO_2$ the higher-melting form is obtained; heating the higher-melting form at 250–70° for 15 min. gives the form m. 156–8°. Dehydrogenation of either form with Br, $KMnO_4$ or S gives *2,3,4,5-tetraphenylbenzophenone* (IX), m. 190°; with $NaNH_2$ IX gives $C_6H_2Ph_4$.  , Bz-CH_2CH_2Cl, AcOK and PhMe, heated 2 hrs., give the addn. compd.  , yellow, m. 189–90°; crystn. from hot AcOH and then from $CHCl_3$-MeOH gives  , yellow, m. 194–5. Biphenylenediphenylcyclopentadienone and $BzCH_2CH_2Cl$

give the *addn. compd.* (X), m. 273°; above its m. p. it dissocs. appreciably into its components; with $BzCH_2$-CH_2NMe_2 there results a dihydro-bridged ketone (XI), m. 312–15°. Me β-benzoylacrylate and 2,3-diphenylbu-

(X) (XI)

tadiene, heated 15 hrs. at 165°, give 52% of *Me 2-benzoyl-4,5-diphenyltetrahydrobenzoate* (XII), $C_{27}H_{24}O_3$, m. 147°; it also results in 20% yield by refluxing the components in xylene for 60 hrs. XII does not react with Br in cold $CHCl_3$ but on warming HBr is evolved, giving a *dibromide*, $C_{27}H_{22}O_3Br_2$, m. 183° (decompn.). Dehydrogenation of XII gives 3,4,6-$Ph_2(HO_2C)C_6H_2Bz$, m. 240–1°. Et sorbate (12.8 g.) and 16.8 g. $BzCH_2CH_2Cl$ with AcOK in xylene, refluxed 18 hrs., give 13.4 g. of mixed esters, b_3 165–70°; hydrolysis with EtOH-KOH gives the mixed isomers, $MeCH.CH_2.CHBz.CH(CO_2H).CH:CH$ or $MeCH.CHBz.CH_2.CH(CO_2H).CH:CH$, m. 128–33°; crystn. from EtOH gives 75% of 1 form, m. 162–3°. Dehydrogenation of the mixed ester, hydrolysis and heating with 20% fuming H_2SO_4 give β-methylanthraquinone; thus the keto acid was almost entirely 2,4-benzoylmethylbenzoic acid. Tetraphenylcyclopentadienone and PhCH:CHBz in $C_6H_3Cl_3$, refluxed 24 hrs., give Ph_5C_6Bz, which yields C_6HPh_5 with $NaNH_2$. Methyleneanthrone and *trans*-(:CHBz)$_2$ in $C_6H_3Cl_3$ give *bz-1-bz-2-dibenzoylbenzanthrone*, m. 208°; in $PhNO_2$ the polymorphic form, m. 286°, is formed; oxidation with CrO_3 gives Va. Furan, sylvan or 2,5-dimethylfuran do not add II. In EtOH II and furan give V (2,4-dinitrophenylhydrazone, orange, m. 158°). Details are given of the isolation of II in 71–8% yield from the reaction of $BzCH_2CH_2Cl$ and AcOK in EtOH; II forms a dimer on standing at room temp.; a specimen contg. hydroquinone becomes viscous in 6 weeks but is not further changed after 5 years.

C. J. West

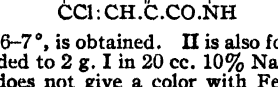
Chalcones: Production of isoxazoles from some chalcone derivatives. R. B. Shenoi, R. C. Shah and T. S. Wheeler. *J. Chem. Soc.* 1940, 247–51.—The action of NH_2OH in the presence of alkali on a RCOCHBrCHBrR′ (I) provides an unambiguous synthesis of the resulting isoxazole (II) and the reaction can therefore be employed to det. which of the 2 possible isoxazoles (II (RC:CH.CR′:N.O) or III (R′C:CH.CR:N.O)) is obtained from the related R′COCH$_2$COR (IV) and NH_2OH. No simple relation can be traced between the substituents in IV and the structure of the preferred II. *p-Anisyl p-methylstyryl ketone* (V), yellow, m. 126°; *β-naphthyl styryl ketone* (VI), yellow, m. 106°; *o*-HOC_6H_4COCH:CHPh and Br in CS_2 give *o-hydroxyphenyl α,β-dibromophenylethyl ketone*, m. 192°; V yields *p-anisyl α,β-dibromo-β-p-tolylethyl ketone* (VII), m. 169°; a C_5H_5N soln. of VII, heated at the b. p. for 0.5 min., gives *p-anisyl α-bromo-p-methoxystyryl ketone*, yellow, m. 129°. VI forms *β-naphthyl α,β-dibromo-β-phenylethyl ketone* (VIII), m. 173°; C_5H_5N gives *β-naphthyl α-bromostyryl ketone*, yellow, m. 116°. Boiling VII with MeONa in MeOH for 1.5 hrs. gives *p*-anisoyl-*p*-toluylmethane, yellow, m. 104°; it also results from the action of dil. HCl on *p*-tolyl *β-p*-dimethoxystyryl ketone (obtained as an oil from *p*-tolyl *α,β*-dibromo-*β-p*-anisylethyl ketone and MeONa). VIII yields *benzoyl-β-naphthoylmethane*, yellow, m. 99°. The II were prepd. by 3 methods: IV is boiled with $NH_2OH.HCl$ in EtOH with or without alkali; an EtOH soln. of the corresponding I contg. $NH_2OH.HCl$ is treated gradually at the b. p. during 30 min. with aq. alkali, cooled and dild. with H_2O; the chalcone ether is boiled with $NH_2OH.HCl$ with addn. of aq. NaOH to form a neutral or alk. soln. or of excess of AcONa. The following new *isoxazoles* are reported: *3-p-anisyl-5-p-tolyl*, m. 148°; *5-p-anisyl-3-p-tolyl*, m. 130°; *5-phenyl-3-o-hydroxyphenyl*, m. 231°; *3-phenyl-5-(3′,4′-methylenedioxyphenyl)*, m. 130° (*6′-Br deriv.*, m. 157°); *5-phenyl-3-(6′-bromo-3′,4′-methylenedioxyphenyl)*, m. 179°; *3-phenyl-5-β-naphthyl*, m. 160°; *5-phenyl-3-β-naphthyl*, m. 152°. An examn. of the results shows that with *p*-NO_2, *o*-HO, *p*-MeO and *p*-Me derivs. of CH_2Bz_2, the Ph group is in the 5-position in the isoxazoles; i. e., the carbonyl-C atom to which the N atom becomes attached is remote from the Ph group. With 3,4-CH_2O_2, 6-Br-3,4-CH_2O_2 and Ph derivs. of CH_2Bz_2 and with $BzCH_2COCH$:CHPh and $BzCH_2C_{10}H_7$-β, 3-phenylisoxazoles are formed. *p*-Tolyl takes the 3-position in preference to *p*-anisyl and the methylenedioxyphenyl group; the latter also takes the 5-position in the product from 4-chloro-3′,4′-methylenedioxydibenzoylmethane.

C. J. West

Condensations brought about by bases. IX. The relationship between the Claisen and Perkin types of condensations. Charles R. Hauser and David S. Breslow. *J. Am. Chem. Soc.* 62, 593–7 (1940); cf. *C. A.* 34, 1618[8].—The mechanisms for the Claisen and Perkin types of condensation are compared and reactions in which both types of condensation are possible are discussed. It is shown that in the presence of EtONa iso-$PrCO_2Et$ does not condense with BzH. The condensation product that would be formed, Et β-phenyl-β-hydroxypivalate (I), is decompd. by EtONa to give BzH and iso-$PrCO_2Et$. Although iso-$PrCO_2Et$ condenses with BzH in the presence of Ph_3CNa to give I, the latter on standing in the presence of this base is again decompd. The mechanisms of these decompns. are discussed.

C. J. West

Interaction of sulfuryl chloride with arylamides of aromatic acids. III. G. V. Jadhav and D. R. Sukhatankar. *J. Univ. Bombay* 8, Pt. 3, 170–3 (1939); cf. *C. A.* 34, 1640[8].—As previously found (*C. A.* 33, 5827[2]) the basic part of a mol. contg. 2 aromatic rings is deactivated by the introduction of an electron-accepting group such as NO_2. To study the effect of the introduction of a NO_2 group into the acidic part of the mol., the anilides and *o*- and *p*-toluidides of *m*- and *p*-nitrobenzoic acid are prepd. The mol. is so much deactivated that the reaction in some cases can be carried out only by boiling the reagents without any solvent. Even under these drastic conditions only mono-Cl derivs. with Cl in the basic part of the mol. can be obtained. *m*-Nitro-*p*′-chlorobenzanilide (I), prepd. by refluxing 3 g. *m*-$NO_2C_6H_4$-CONHPh and 5 g. SO_2Cl_2, m. 175°; *m*-nitrobenzo-*o*-toluidide, prepd. from *o*-$MeC_6H_4NH_2$ and *m*-$NO_2C_6H_4$-COCl, m. 154°; *m*-nitro-5′-chlorobenzo-*o*-toluidide (Me = 1′), prepd. as I, m. 183°; *m*-nitro-3′-chlorobenzo-*p*-toluidide, m. 173°; *p*-nitro-*p*′-chlorobenzanilide, m. 219°; *p*-nitro-5′-chlorobenzo-*o*-toluidide, m. 210°; *p*-nitro-3′-chlorobenzo-*p*-toluidide, m. 158°.



F. E. Brauns

Racemization of carboxylic esters by sodium ethoxide and its bearing on Claisen's condensation. J. Kenyon and D. P. Young. *J. Chem. Soc.* 1940, 216–18.—The optically active ester was added to 1 mol. (or less) of an approx. satd. soln. of the alkoxide in the corresponding alc. After the appropriate interval a slight excess of cold dil. HCl was added and the liberated ester extd. with ether. The amt. of distd. ester recovered was of the order of 80–90%; the rest of the reaction product was generally insufficient for anything but a detn. of its b. p. which was much higher than that of the ester from which it was derived. (−)-$PhMeCHCO_2Me$ is completely racemized with 1 mol. proportion of MeOK in 20 hrs. at room temp. (5% with 0.042 mol.) and 98.7% with 0.5 mol. EtONa in 24 hrs. (56.8% in 10 sec.). (−)-$EtBuCHCO_2$-Et is unchanged after 5 min. with 1 mol. EtONa, 10% in 20 hrs. and 100% in 20 min. at 80°. (−)-$MeEtCHCO_2Et$ is completely racemized with K in 15 min. and with EtONa after 70 hrs. at room temp. or 45 min. at 80° (15% after 1 hr. and 68% after 40 hrs. at room temp.). This is considered to afford strong support for the view that ionized Na derivs. of the esters are formed under these conditions as has been suggested in several postulated mechanisms for Claisen's condensation.

C. J. West

Tautomerism of phenylbutenoic acids. N. L. Phalnikar and K. S. Nargund. *J. Univ. Bombay* 8, Pt. 3, 184–9 (1939); cf. *C. A.* 32, 4152⁸.—In continuation of the study of the influence of an α-Ph group on tautomerism, the equil. systems of 3,4-diphenyl-2-butenoic acid ⇄ 3,4-diphenyl-3-butenoic acid and 2,3-diphenyl-2-butenoic acid ⇄ 2,3-diphenyl-3-butenoic acid are studied. Et β,γ-diphenyl-β-hydroxybutyrate (I), m. 60°, is prepd. from CH_2BrCO_2Et and desoxybenzoin according to Reformatskiĭ. Sapon. of I gives the free acid (II), m. 126–7°. When 25 g. II is refluxed with 38 g. Ac_2O for 3 hrs. 12 g. *3,4-diphenyl-2-butenoic acid* (III), m. 114°, is obtained. Its *anilide* m. 135°; *p-toluidide*, m. 156°; *Et ester*, prepd. from the Ag salt and EtI, b_{10} 210°. The constitution of III is proved by ozonization whereby desoxybenzoin is formed as the only product. *3,4-Diphenyl-3-butenoic acid* (IV), m. 173°, is prepd. by refluxing 28 g. $PhCH_2C(OH)PhCH_2CO_2Et$ (V) in 50 cc. C_6H_6 and 21 g. P_2O_5 for 3 hrs. The *Et 3,4-diphenyl-3-butenoate* b_{12} 210–15° and on hydrolysis gives IV. The *anilide* of IV m. 172°; *p-toluidide*, m. 160–1°. Oxidation of IV with $KMnO_4$ in alk. soln. gives BzOH. Attempts to dehydrate V with $KHSO_4$, $POCl_3$ or $SOCl_2$ and pyridine were unsuccessful. α,β-Diphenyl-β-hydroxybutyric acid (VI), m. 192°, is prepd. according to Ivanoff and Spasoff (*C. A.* 25, 2987) who found a m. p. of 182°. Dehydration of VI is carried out by refluxing it with Ac_2O for 3 hrs., giving *2,3-diphenyl-2-butenoic acid* (VII), m. 160°. Its constitution is proved by ozonization whereby PhCOMe and BzOH are obtained. The *anilide* of VII m. 148°. Esterification of VII with EtOH contg. 5% HCl gives the *Et ester* (VIII), b_{10} 130°. All dehydration expts. with VIII failed. For the detn. of the mixt. of the unsatd. acids the Br addn. method of Kon, Linstead and Wright (*C. A.* 28, 4699³) is used and the results calcd. by the method of P. and N. They show that III and IV have an equil. of 17% of α,β-isomeride which indicates the influence of a β-Ph group. The existence of 100% of α,β-isomeride in VII confirms the conclusion of Goldberg and Linstead (*C. A.* 23, 96) that butenoic acids with no γ-substituents show no stability of the β,γ-form even when substituted on the β-C. F. E. Brauns 1

Dehydration product of chloral-3,5-dichlorosalicylamide. N. W. Hirwe and K. N. Rana. *J. Univ. Bombay* 8, Pt. 3, 243–6 (1939).—When 5 g. chloral-3,5-dichlorosalicylamide (I) (*C. A.* 33, 7760²) is dissolved in 20 cc. concd. H_2SO_4, allowed to stand for 24 hrs. and then poured on ice, *6,8-dichloro - 2 - trichloromethyl - 1,3,2 - benzoxaz - 4(3) - one*

(II), m. 176–7°, is obtained. II is also formed when 2 cc. Ac_2O is added to 2 g. I in 20 cc. 10% NaOH. II is insol. in alkali, does not give a color with $FeCl_3$ and forms a *mono-Ac deriv.*, m. 123–5°. Warming of II with aq. NH_4OH (d. 0.888) yields *α-aminochloral-3,5-dichlorosalicylamide* (III), m. 125–7°. III is sol. in NaOH and gives a red color with $FeCl_3$. Its *Ac deriv.* m. 207–8°. III forms a *HCl salt* and a *sulfate*. Heating of III with dil. NaOH gives 3,5-dichlorosalicylic acid. Treatment of III with NO_2 gives I, m. 158–9° (decompn.). II may also have the imino hydroxy structure. F. E. Brauns 2

Condensation of *p*-methoxyphenylsuccinic anhydride with anisole and cresol methyl ethers. G. A. Dalal, K. V. Bokil and K. S. Nargund. *J. Univ. Bombay* 8, Pt. 3, 190–7 (1939).—Condensation of O.CO.GHR.CH_2.CO by the Friedel-Crafts reaction yields 2 different γ-keto acids in various amts. depending upon the solvent used. O.CO.CH(*p*-$MeOC_6H_4$).CH_2.CO (I) is condensed with PhOMe (II) and with cresol Me ethers using different solvents. In $PhNO_2$ or CS_2 I and II give *α-p-methoxyphenyl-β-p-methoxybenzoylpropionic acid* (III), m. 163°, in 77% and 35% yield, resp. In $(CHCl_2)_2$ (IV) III is obtained in 95% yield in addn. to a small amt. of a compd. m. 83°. The constitution of III is proved by its synthesis according to the method of Hahn and Lapworth (*J. Chem. Soc.* 85, 1358 (1904)). III is also obtained when *α-p*-methoxyphenyl-β-*p*-methoxybenzoyl-α,β-dibromoethane reacts with KCN and the CN compd. formed is hydrolyzed. Oxidation of III with $KMnO_4$ gives anisic acid, m. 180°. With *o*-HOC_6H_4CHO (V) and HCl, III forms a pyrylium deriv. The *Me ester* of III m. 98°; *Et ester*, m. 85°. *o*-MeC_6H_4OMe and I give, in various solvents, *α-p-methoxyphenyl-β-4-methoxy-m-toluylpropionic acid* (VI), m. 170°, in 95% yield in IV, 65% in CS_2 and 92% in $PhNO_2$. 3-Methyl-4-methoxyacetophenone (VII), prepd. by methylating the HO deriv. (cf. Nencki and Stober, *Ber.* 30, 1770), b. 260–5°. VII and anisaldehyde give *4,4'-dimethoxy-3'-methylchalcone* (VIII), an oil, which on treating with Br yields *α-p*-methoxyphenyl-β-3-methyl-4-methoxybenzoyl-α,β-dibromoethane (IX), m. 121°. Neither VIII nor IX reacts with KCN. A synthesis of VI is achieved by treating a Grignard reagent prepd. from 2-methoxy-5-bromotoluene with I. The *Me ester* of VI m. 98°; *Et ester*, m. 82°. *α-p-Methoxyphenyl-β-4-methoxy-o-toluylpropionic acid* (X), obtained from *m*-MeC_6H_4OMe and I, in 90% yield in IV, 15% in CS_2 and 75% in $PhNO_2$, m. 148°. Its *Me ester* b_8 210–15°; its pyrylium deriv., insol. in dil. NaOH, is deep red and does not m. up to 300°. X is synthesized from 4-methoxy-2-methylacetophenone and anisaldehyde, giving 4,4'-dimethoxy-2'-methylchalcone (XI), m. 147°, which on treatment with Br yields *α-p*-methoxyphenyl-β-4-methoxy-*o*-toluyl-α,β-dibromoethane, m. 160°. On treatment with KCN followed by hydrolysis, it gives X. *α-p-Methoxyphenyl-β-6-methoxy-m-toluylpropionic acid* (XII), m. 168°, is prepd. from *p*-MeC_6H_4OMe and I in 90% yield in IV, 10% in CS_2 and 45% in $PhNO_2$. Its *Me ester* b_{18} 250°; *Et ester*, m. 95°. The synthesis of XII from 2-methoxy-5-methylacetophenone, b_8 120°, b. 154°, failed since the latter could not be condensed with anisaldehyde to the corresponding chalcone. Its synthesis, however, is achieved by the reaction of a Grignard reagent from 3-bromo-4-methoxytoluene on I. XII gives a deep red pyrylium deriv. which does not m. up to 300°. **Condensation of *p*-methoxyphenylsuccinic anhydride with the methyl ethers of pyrocatechol, resorcinol and hydroquinone.** G. S. Savkar, K. V. Bokil and K. S. Nargund. *Ibid.* 198–202.—Condensation of I with veratrole gives *α-p-methoxyphenyl-β-3,4-dimethoxybenzoylpropionic acid* (XIII), m. 188°, in 64% yield in $PhNO_2$ and 85% in IV, while in CS_2 no reaction takes place. The *Me ester* of XIII m. 138°; *Et ester*, m. 88°; *semicarbazone*, m. 176°. Condensation of XIII with V gives a deep red pyrylium deriv. which does not m. up to 300°. XIII is synthesized by the reaction of KCN with *α-p*-methoxyphenyl-β-3,4-dimethoxybenzoyl-α,β-dibromoethane, m. 138°, prepd. from 4,3',4'-trimethoxychalcone and sapon. of the CN deriv. Guaiacol, *p*-$C_6H_4(OH)_2$ and *p*-HOC_6H_4OMe do not condense with I. *m*-$C_6H_4(OMe)_2$ and I give *α-p-methoxyphenyl-β-2,4-dimethoxybenzoylpropionic acid* (XIV) m. 201°, in 64% yield in $PhNO_2$, 34% in IV, and 95% in CS_2. The *Me ester* of XIV m. 107°; *Et ester*, m. 112°; *semicarbazone*, m. 211°. 2',4',4-Trimethoxychalcone, m. 86°, is prepd. from resacetophenone di-Me ether and anisaldehyde. Addn. of Br gives *α-p*-methoxyphenyl-β-2,4-dimethoxybenzoyl-α,β-dibromoethane, m. 118°, which reacts with KCN but no cryst. acid is obtained from the reaction. XIV, however, is synthesized from I and a Grignard reagent prepd. from 4-iodoresorcinol di-Me ether. *m*-$MeOC_6H_4OH$ and I give *α-p-methoxyphenyl-β-2-hydroxy-4-methoxybenzoylpropionic acid* (XV), m. 169°, in 69% yield in $PhNO_2$, 78% in IV, and 21% in CS_2. Its *Me ester*, prepd. from the Ag salt and MeI, m. 92°; *Et ester*, m. 111°; *semicarbazone*, m. 157°. *p*-$C_6H_4(OMe)_2$ and I give *α-p-methoxyphenyl-β-2,5-dimethoxybenzoylpropionic acid* (XVI), m. 168°, in 29% yield in $PhNO_2$ and 14% in IV. Its *Me ester* m. 102°; *Et ester*, m. 75°; *semicarbazone*, m. 126°. XVI is synthesized from 4,2',5'-trimethoxychalcone, m. 99°, by addn. of Br, giving *α-p*-methoxyphenyl-β-2,5-dimethoxybenzoyl-α,β-dibromoethane, m. 112°, and hydrolysis of the corresponding CN deriv. **Condensation of succinic anhydride** 3 4 5 6 7 8 9

with the methyl ethers of orcinol and pyrogallol. G. A. Dalal, K. V. Bokil and K. S. Nargund. *Ibid.* 203–4.—I and orcinol di-Me ether give *β-2,4-dimethoxy-6-methylbenzoylpropionic acid* (XVII), m. 120°, in 40% yield in CS_2, 60% in $PhNO_2$ and 45% in IV. The *Me ester* b_{16} 160°; *Et ester*, b_{20} 170°. Orcinol mono-Me ether and I give *β-2-methoxy-4-hydroxy-6-methylbenzoylpropionic acid*, m. 145°, in 25% yield in $PhNO_2$. When recrystd. from H_2O, it m. 125°. It gives no color with $FeCl_3$ and on methylation gives XVII. I and pyrogallol tri-Me ether give *β-2-hydroxy-3,4-dimethoxybenzoylpropionic acid*, m. 153°; its *Me ester* m. 110°; *Et ester*, m. 58°; *semicarbazone*, m. 185°. F. E. Brauns

Condensation of α-substituted acetoacetates with phenols. II. Use of various condensing agents with ethyl α-acetoglutarate. N. M. Shah. *J. Univ. Bombay* 8, Pt. 3, 205–7(1939); cf. *C. A.* 33, 5481.—Et α-acetoglutarate (I) reacts with phenols in the presence of H_2SO_4 with the formation of coumarin-3-propionic acid derivs. Since the course of the reaction is affected by the condensing agent, P_2O_5 (II), H_3PO_4 (III), $AlCl_3$ (IV) and gaseous HCl (V) are tried as condensing agents. *m*-$C_6H_4(OH)_2$ and I give with II, III and IV 7-hydroxy-4-methylcoumarin-3-propionic acid, m. 224°, IV giving the highest yield. Orcinol and I with V give Et 5-hydroxy-4,7-dimethylcoumarin-3-propionate, m. 162–3°, and with II the corresponding free acid. Pyrogallol and II, α-naphthol and II or III, β-naphthol and II or IV, and *m*- and *p*-cresols with any condensing agent give no definite product. F. E. Brauns

γ-Substitution in the resorcinol nucleus. V. The Gattermann reaction with 4-acylresorcinols. H. A. Shah and R. C. Shah. *J. Chem. Soc.* 1940, 245–7; cf. *C. A.* 33, 6813[3].—Respropiophenone (10 g.) in AcOH, treated with 14 g. of $Zn(CN)_2$ and 1.5 g. KCl and then with 16 g. $AlCl_3$ in ether, HCl passed through for 4 hrs., 200 cc. H_2O added and the mixt. heated for 0.5 hr. at 100°, gives 7.5 g. of *2,4-dihydroxy-3-formylpropiophenone* (I), m. 140 1°; alkali gives a bright yellow color and EtOH-$FeCl_3$ gives a deep red color; *2,4-dinitrophenylhydrazone*, yellow, m. 265–7° (decompn.). I (1 g.) and 1 g. $NCCH_2CO_2H$ in 15 cc. 20% NaOH give 0.9 g. of *5-hydroxy-6-propionylcoumarin-3-carboxylic acid*, straw-colored, m. 185–6° (decompn.); I (1 g.), 1 g. $AcCH_2CO_2Et$ and 4 drops piperidine give 0.6 g. of *5-hydroxy-3-acetyl-6-propionylcoumarin*, yellow, m. 188–90°. 2-Methylresorcinol (II) (1 g.) and 1 g. EtCN in 30 cc. ether, satd. with HCl in the presence of $ZnCl_2$, give 0.5 g. of *2,4-dihydroxy-3-methylpropiophenone*, m. 128–30°; Clemmensen reduction yields *2-methyl-4-propylresorcinol* (III), m. 102–3°; $AcCH_2CO_2Et$ and H_2SO_4 give *7-hydroxy-4,8-dimethyl-6-propylcoumarin*, m. 160–2°. Reduction of I by Clemmensen's method gives III, proving its constitution. Resobutyrophenone, $Zn(CN)_2$, $AlCl_3$ and KCl with HCl give *2,4-dihydroxy-3-formylbutyrophenone* (IV), yellow, m. 42–3° (*semicarbazone*, m. 242–5° (decompn.)); $NCCH_2CO_2H$ gives *5-hydroxy-6-butyrylcoumarin-3-carboxylic acid*, straw-colored, m. 198–200° (decompn.). II, PrCN, $Zn(CN)_2$ and HCl give *2,4-dihydroxy-3-methylbutyrophenone*, straw, m. 155–7°; Clemmensen reduction gives *2-methyl-4-butylresorcinol*, m. 74–6°, which is also formed from IV. 2,4-$(HO)_2C_6H_3Bz$ (10 g.) gives 4 g. of *2,4-dihydroxy-3-formylbenzophenone* (V), pale yellow, m. 117–18°; *2,4-dinitrophenylhydrazone*, yellow, m. 228–30° (decompn.); $NCCH_2CO_2H$ gives *5-hydroxy-6-benzoylcoumarin-3-carboxylic acid*, m. 244° (decompn.); Clemmensen reduction of V gives *4-benzyl-2-methylresorcinol*, m. 96–8°, also prepd. from 3,2,4-$Me(HO)_2C_6H_2Bz$. 2,4-$(HO)_2C_6H_3COCH_2Ph$ (10 g.) gives 6 g. of *2,4-dihydroxy-3-formylphenyl benzyl ketone*, m. 110.5–12°; *2,4-dinitrophenylhydrazone*, yellow, m. 252–3° (decompn.); *semicarbazone*, m. 248–9° (decompn.)); $CH_2(CO_2Et)_2$ gives *Et 5-hydroxy-6-phenylacetylcoumarin-3-carboxylate* (VI), yellow, m. 200–1°; $AcCH_2CO_2Et$ gives *5-hydroxy-3-acetyl-6-phenylacetylcoumarin*, yellow, m. 198–200°; $NCCH_2CO_2H$ gives the free *acid* corresponding to VI, m. 215–17° (decompn.); II and $PhCH_2CN$ give *2,6-dihydroxy-m-tolyl benzyl ketone*, m. 157–9°; reduction gives *2-methyl-4-β-phenylethylresorcinol*, m. 115–16° (*di-p-nitrobenzoyl deriv.*, straw-colored, m. 140–2°).

C. J. West

Synthesis of 3-aminocoumarin. Kantilal C. Pandya and Tejpal S. Sodhi. *J. Univ. Bombay* 8, Pt. 3, 173–5 (1939); cf. *C. A.* 33, 7300[4].—When 3 g. *o*-HOC_6H_4CHO, 1.25 g. $NH_2CH_2CO_2H$ and 0.1 cc. pyridine are heated in an oil bath at 130–40° for 5 hrs., the reaction product extd. with EtOH and the latter distd. off, 3-aminocoumarin, m. 130°, is pptd. in 81% yield on addn. of H_2O.

F. E. Brauns

Condensation of nitroanilines and diaminobenzenes with the anhydride of phthalic acid. J. Hadáček. *Časopis Českého Lékárnictva* 19, 183–191, 199–207(1939).—*o*-Nitroaniline gives $C_{14}H_8O_4N_2$ (I), m. 164°; *m*-nitroaniline, $C_{20}H_{14}O_8N_4$ (II), m. 265°; *p*-nitroaniline, $C_{20}H_{16}O_8N_2$ (III), m. 196°; *o*-diaminobenzene, $C_{16}H_{12}O_2N_2S$ (IV), m. 261°; *m*-diaminobenzene, m. 198°; *p*-diaminobenzene, m. 196°; the formulas for the last 2 compds. were not detd. By the chlorination of I there was obtained dichloronitroacetanilide; of II, tetrachloroaniline-HCl; of III, chloroacetanilide; and of IV, tetrachloroaminophenylphthalimide. Bromination of I gave dibromonitroaniline; of II, tribromonitroacetanilide and bromonitroacetanilide; of III, tribromoacetanilide; and of IV, dibromoaminophenylphthalimide. V. D. Karpenko

Nature of addition of aliphatic diazo compounds to conjugated double-bonded systems; action of diazomethane and ethyl diazoacetate on cyclopentadiene and cyclohexadiene and their derivatives. P. C. Guha and G. D. Hazra. *J. Indian Inst. Sci.* 22A, 263–74(1939).—Cyclopentadiene (I) could not be induced to react with CH_2N_2 in dry ether at 0°, at room temp. or in the presence of MeOH as catalyst. I reacted with N_2CHCO_2Et at 0°, but exploded when warmed to room temp. 1,3-Cyclohexadiene (II) did not react with CH_2N_2. *Et norcarene-carboxylate* (III) was prepd. in a 64% yield from a warm mixt. of 16 g. II with 1.5 g. Cu bronze under reflux by adding dropwise 22.5 g. N_2CHCO_2Et, heating on the H_2O bath for 6 hrs., filtering and fractionally distg. at 84°/2.5 mm. The structure of III was established by hydrolysis to *norcarenecarboxylic acid*, m. 82.5° (*anilide*, m. 195–96°); and by reducing catalytically to *Et norcaranecarboxylate*, b_{18} 112–14°, which was hydrolyzed to *norcaranecarboxylic acid* (IV), m. 97°. The Ba salt of IV when distd. with ZnO gave *norcarane*. These compds. are identical with those of Ebel, Brunner and Mangeli (*C. A.* 23, 2707[6]). 2,3-Dimethyl-1,3-cyclohexadiene (cantharene) (V), b. 135°, was prepd. by heating 40 g. dimethyldibromocyclohexane with 90 g. freshly distd. quinoline. It was purified by redistg., washing with dil. HCl and H_2O, drying over $CaCl_2$ and distg. thrice over Na. V did not react with CH_2N_2. To 23 g. V with 0.5 g. Cu bronze heated to 70° 24.2 g. N_2CHCO_2Et was added dropwise and allowed to stand for 17 hrs. After filtration, about 9 g. unreacted V was removed by distn. to 140°. The residual liquid on fractional distn. gave an oil, $b_{2.5}$ 91–5°; yield, 11 g. The product, *Et dimethylnorcarenecarboxylate*, was hydrolyzed with 5% alc. KOH, giving in very poor yield a C_6H_6-sol. acid, m. 140°, and a C_6H_6-insol. acid, m. 282°. *Di-Me 2,3-dihydroterephthalate* (VI) was prepd. from *di-Me terephthalate* (VII); 40 g. VII, 5 g. Pt oxide (Adam's catalyst) and 250 cc. glacial AcOH were placed in a soda-water bottle, the air removed and the bottle connected with an aspirator contg. H under 3 atm. pressure and shaken mechanically at room temp. for 2.5 hrs. The mixt. was filtered and freed from AcOH by distn. and washing with H_2O. The residual oily liquid gave 37 g. *di-Me hexahydroterephthalate* (VIII), b_2 132–3°. VIII (146 g.) heated under reflux with 1.5 l. 8% HCl for 6 hrs., the clear soln. evapd. nearly to dryness, cooled, filtered and the solid residue consisting of 125 g. of a mixt. of *trans-* and *cis-hexahydroterephthalic acids* (IX) was extd. with $CHCl_3$; 85 g. of the cis acid, m. 168–70°, was obtained from the soln., and 42 g. of the trans acid, m. 308°, was left undissolved in the $CHCl_3$. *cis-IX* (20 g.) was converted into the acid chloride with $SOCl_2$. The excess $SOCl_2$ was removed under suction and the diacid chloride

was heated with 40 g. Br at 150° for 4 hrs. After cooling in a freezing mixt., excess abs. MeOH was added, and the soln. allowed to stand overnight and then heated for 3 hrs. under reflux on the H_2O bath. The MeOH was removed by distn. and the residual liquid poured into ice-cold $NaHCO_3$ soln. when a mixt. of the *cis*- and *trans-di-Me 1,4-dibromohexahydroterephthalates* sepd. out. The solid trans ester, sepd. by filtration and crystd. from MeOH, m. 150°; yield, 10 g. The liquid cis ester, purified by distn. under reduced pressure, soon solidified, and m. 68°; yield, 11 g. A mixt. of the *trans*-Br ester (81 g.) and the *cis*-Br ester (69 g.) was treated with 750 g. 50% alc. KOH and the mixt. allowed to stand at room temp. with frequent trituration for 48 hrs. The paste was acidified with dil. H_2SO_4 under ice-cooling when *2,3-dihydroterephthalic acid* sepd. out (application of heat tends to the formation of the *2,5-isomer*). The acid was converted to the acid chloride by $SOCl_2$ and the latter converted into VI by heating under reflux with MeOH for 3 hrs., then poured into H_2O and the monoester removed by Na_2CO_3 soln. VI, purified by crystn. from MeOH, m. 85°; yield, 25 g. VI (20 g.) was treated with 4.2 g. CH_2N_2 in ether at 0° for 2 days. After removal of the ether, N was removed by heating at 140°, caution being necessary to prevent an explosion. Yield of *di-Me bicyclo[2.2.1]heptenedicarboxylate* (X), b_3 132–34°, 13 g. To prove that addn. had taken place in the 1,4-position, the free acid of X was oxidized with 3% $KMnO_4$ at 0° in Na_2CO_3 soln. to give *cyclopentane-1,1,3,3-tetracarboxylic acid*, m. 188°, identical with a genuine sample previously prepd. (*C. A.* **30**, 5208[7]). Conclusions: (1) CH_2N_2 does not react with 5- and 6-membered cyclic hydrocarbons contg. a system of conjugated double bonds. (2) N_2CHCO_2Et reacts with them, giving 1,2-addn. products. (3) When the C atoms in positions 1 and 4 carry neg. groups like CO_2Et, the addn. of CH_2N_2 takes place in the 1,4-positions.

Mark Plunguian

Condensation product of methyl *o*-aldehydobenzoate and malonic acid. S. Hanai. *Bull. Inst. Phys. Chem. Research* (Tokyo) **17**, 1236–40(1938).—*o*-$OHCC_6H_4CO_2Me$ and $CH_2(CO_2H)_2$ yield a compd., m. 311–12°, a decompn. product of which is *o*-$HO_2CC_6H_4(CH_2)_2CO_2H$. Diphthalide ether m. 235–36°. B. C. P. A.

The catalytic oxidizing properties of the phthalocyanines. Charles Paquot. *Compt. rend.* **209**, 171-3(1939).—*α*-Pinene oxidized with 2.5–5% Fe (I), Co (II), Ni (III) phthalocyanines at 50–100° for 8–40 hrs. yields 10–25% *verbenone* (IV), 1–3% *pinacol hydrate* and 40–70% unoxidized pinene. Oxidation with II at 100° yields in addn. 2–7% *verbenene*, resulting from the dehydration of verbenol. The optimum condition for the prepn. of IV are: III (as catalyst) 0.5–1%, temp., 80°, time, 30–50 hrs.; yield 40–50%. Oxidation of cyclohexene with III (0.4%) for 60 hrs. at 65° yields *3-cyclohexen-1-one* (17%), *3-cyclohexen-1-ol* (6%), *1,3-cyclohexadiene* (2%), *epoxycyclohexane* (2%) and *1,2-cyclohexanediol* (4%). The identification of the different fractions is confirmed by a study of their Raman spectra. C. W. Sondern

Optical superposition. H. Rupe and Franz Häfliger. *Helv. Chim. Acta* **23**, 53–90(1940); cf. *C. A.* **30**, 5960[7].—To test the principle of optical superposition the esters of *d*-, *l*- and *dl*-camphorylmethanol (I) and of the corresponding unsatd. *d*-, *l*-, and *dl*-hydroxymethylenecamphor (II) with *d*- and *dl*-camphorylacetic acid (III), *d*- and *dl*-camphorylpropionic acid (IV) and *d*- and *dl*-camphorylideneacetic acid (V) were prepd. and polarimetrically examd. *New compds.* are the *dl*-forms of IV, m. 85° (active form, m. 63–64°), of V, m. 143° (active form, m. 99.5–101°), and of III, m. 115° (active form, m. 83–84°), and the esters, *d*-II *d*-IV, m. 143°; *l*-II *d*-IV, m. 133°; *d*-II *dl*-IV, m. 128°; *l*-II *dl*-IV, m. 126 *dl*-II *d*-IV, m. 139°; *d*-I *d*-IV, m. 90°; *l*-I *d*-IV, m. 113 *d*-I *dl*-IV, m. 94°; *l*-I *dl*-IV, m. 96°; *dl*-I *d*-IV, m. 94 *d*-*β*-I *d*-IV, m. 103°; *d*-II *d*-V, m. 145°; *l*-II *d*-V, m. 121 *d*-II *dl*-V, m. 146°; *l*-II *dl*-V, m. 146°; *dl*-II *d*-V, m. 143 *d*-I *d*-V, m. 102°; *l*-I *d*-V, m. 90°; *d*-I *dl*-V, m. 90 *l*-I *dl*-V, m. 91°; *dl*-I *d*-V, m. 92°; *l*-II *d*-III, m. 111 *d*-II *dl*-III, m. 101°; *dl*-II *d*-III, m. 120°. Camphorylidenepropionic acid (VI) gives no acid chloride but a lactone with $SOCl_2$, while the Na salt of VI with $POCl_3$ gives no acid chloride but only some bismethylenecamphormethane, $(C_{11}H_{16}O)_2CH_2$. The rotations of the esters do not correspond simply to an algebraic sum of two consts., e. g., $[M]_D$ for IV as dctd. from the ester with I is 52.37° while from the ester with II it is −5.70°, indicating the influence of the substituent groups on C*. From the [M] values for the *d*-*d* and *l*-*d* forms of a given ester the *d*-*dl*, *l*-*dl*, *dl*-*d* and *dl*-*l* ester values should be calculable if the principle of optical superposition holds. In the formation of the half-racemic esters, i. e., *dl*-*d* (or -*l*) and *d* (or *l*)-*dl*, partial steric resolution occurs in some cases as the *dl*-component recovered from the sapon. of the ester shows optical activity. R. and H. conclude from a crit. examn. of their data and correcting for errors that the principle of optical superposition is valid for the esters with 1 or both components satd. and is not valid for the esters with both components unsatd. A. P. Sachs

Preparation of borneol glucuronide. Harvey K. Murer and Lathan A. Crandall, Jr. *J. Am. Chem. Soc.* **62**, 674–5(1940).—Zn borneol glucuronide (prepd. by the method of Quick, *C. A.* **21**, 3373)(200 g.) is added with stirring to 800 ml. warm Me_2CO contg. 14.7 ml. concd. H_2SO_4; the $ZnSO_4$ and unreacted Zn salts are sepd. by centrifugation, washed with warm Me_2CO, 50 ml. of H_2O is added to the Me_2CO and borneol glucuronide crystd. at room temp. A more suitable method for the hydrolysis of the glucuronide could not be found. C. J. West

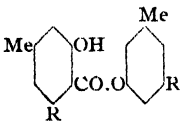
Camphorone and pulegenone. Hydrogenation products and their structure. IV. Hydrogenation in the presence of metal catalysts. Raymond Calas. *Bull. soc. chim.* **6**, 1485-93(1939); cf. *C. A.* **34**, 92[2].—Catalytic hydrogenation of 150 g. of camphorone (I) in the presence of Adams' Pt catalyst in AcOH or in abs. alc. gave 120 g. of a *dihydrocamphorone* (II), b. 179–81° (*semicarbazone* (III), m. 198°), or 145 g. of a *dihydrocamphorone* (IV), b. 179–81° (*semicarbazone* (V), m. 209°). Similar results were obtained by catalytic hydrogenation of pulegenone (VI). The reduction does not stop at the ketone stage, as in reduction in the presence of Raney Ni catalyst, but continues with formation of the alc., $C_9H_{18}O$, in traces since, apparently, the reduction is accompanied by a dehydration. Reduction in the presence of a Pt-Fe catalyst (prepd. from a mixt. of 10 g. dried residue from H_2PtCl_6, 3 cc. of 30% $FeCl_3$, 7 g. of 40% HCHO and 10 cc. H_2O, by pptg. with 10 g. NaOH in H_2O and filtering after 24 hrs.) satd. only the ethylenic linkage. Reduction is most rapidly accomplished in the presence of Pt but excellent results are obtained by the use of large amts. of the less expensive Raney Ni; with Pt-Fe the rates of reduction are very low. In alk. or neutral soln., with any catalyst, the trans form of the dihydrocamphorone is mainly produced; in acid media, the cis form is the main product, in accordance with the views of Skita. VI is reduced more slowly than I in accordance with its intranuclear double bond, in contrast to the nuclear bond in I. **V. cis- and trans-Dihydrocamphorones.** *Ibid.* 1493–8.—A mixt. of 100 g. III, 300 g. $(CO_2H)_2$ and 500 cc. H_2O was boiled for several min., extd. with ether, neutralized with $NaHCO_3$ and distd., yielding 70 g. II, b_{14} 70°; *oxime*, b_{15} 118–19°, m. 76–7°; *carbanilidoxime*, $C_{18}H_{22}N_2O_2$, m. 142°. A similar hydrolysis of V gave IV, b_{14} 70°; *oxime*, b_{16} 117°; *carbanilidoxime*, m. 139°. II has viscosity 0.1563, surface tension 31.10 dynes/cm., parachor 372 (calcd. 369), M. R. 41.44 (calcd. 41.57), and IV has viscosity 0.1577, surface tension 31.20 dynes/cm., parachor 373, M. R. 41.47. The lower M. R. and viscosity of II indicate that it has the cis form, according to the rule of Auwers. A study of the rate of oximation showed that the oxime of IV was formed 1.33 times more rapidly than that of II and this is in accordance with the assignment of a trans structure to IV. IV is mainly produced in the hydrogenation of I or VI in neutral or alk. media and, according to Skita, should have the trans form. A tabular comparison of various synthetic dihydrocamphorones, as reported by divers investigators, shows that *syn*-dihydrocamphorone is mainly IV, whereas the products of oxidation and re-

duction are chiefly II. VI. **Hydrogenation of dihydrocamphorones; transposition of the trans ketone into its cis isomer.** *Ibid.* 1499–1505.—Although catalytic reduction of I or VI gave only the ketones (II and IV), further reduction to a mixt. of *cis*- and *trans*-dihydrocamphorols (VII, VIII) (cf. *C. A.* 18, 1659) is possible by hydrogenation of either II or IV with Na in either ether or abs. alc. This phenomenon can be interpreted by the assumption of an enolization of II and IV to a common enol form prior to reduction. In the presence of iso-PrMgBr in ether, II and IV show 17.2 and 18.5% enolization, resp. Decompn. of the product of the treatment with the Grignard reagent and isolation as the semicarbazone showed that about 15% of IV is in the enol form which, on hydrolysis, yields the cis ketone, as the most stable modification. Thus reduction of II and IV with Na in ether or abs. alc. is preceded by an enolization, after which the double bond is satd. and the Me and iso-Pr groups orient themselves in the more stable cis configuration. The formation of the same dihydrocamphorols from I and VI is similarly explained and the lack of unsatd. alcs. or of dihydrocamphorone on reduction with Na in aq. ether confirms the conception of a reduction of the enolic modification. VII. **Dehydration of the previously described dihydrocamphorols; structure of the corresponding ketone.** *Ibid.* 1505–10.—It has been previously indicated that VII and VIII are derived from a cis ketone (IX) in which the Me and iso-Pr groups are on the same side of the nuclear ring. This assumption is confirmed by the dehydration of VII and VIII to one and the same hydrocarbon, 1-methyl-3-isopropylcyclopentene (X). It is considered that the alcs. corresponding to a trans ketone would give rise to 2 different hydrocarbons. A mixt. of 5 g. VII (prepd. by regeneration from the acid phthalate, m. 114°) and 10 g. $(C_6H_4CO)_2O$ at 130–40° was distd. and the distillate was extd. with ether, yielding 4 g. of X, C_9H_{16}, b. 138–9°, d_4^{18} 0.7935, n_{5893}^{18} 1.44354, M. R. 41.47 (calcd. 41.10), viscosity 0.724, surface tension 27.8 dynes/cm., parachor 358 (calcd. 349); *NOCl deriv.*, m. 119° (piperidide, m. 161°). Accordingly, X is regarded as a pure compd., prepd. for the first time in the pure state, and distinct from the 1-methyl-3-isopropyl-2-cyclopentene which might have been formed by dehydration of VII. Similarly, dehydration of VIII (prepd. from the acid phthalate, m. 84°) gave X. Since dehydration of both VII and VIII gives only X, it is reasoned that the corresponding ketone has the cis configuration by an argument which would be without value if the difference in the lability of the H atoms in positions 2 and 5 is such that the same atom should always combine with the OH group whatever its position with respect to the group. C. R. Addinall

1,2,2 - Trimethylcyclopentane - 1,3 - dialdehyde: (Camphoceandialdehyde). Franz Häfliger. *Helv. Chim. Acta* 23, 90-2(1940).—Camphor glycol (25 g.) in 150 cc. C_6H_6 and 15 cc. AcOH oxidized with 71.6 g. $Pb(OAc)_4$ yields with ring rupture 16 g. (63% of theory) of 1,2,2-trimethylcyclopentane - 1,3 - dialdehyde (camphoceandialdehyde), m. 97°, b_{12} 120–2°. A. P. Sachs

Camphorquinone and diazomethane (preliminary communication). H. Rupe and Franz Häfliger. *Helv. Chim. Acta* 23, 139–43(1939).—Camphorquinone (20 g.) in 90 cc. benzene was chilled and treated with CH_2N_2 in benzene (from 20 g. ON(Me)NCONH$_2$) and 5 cc. MeOH. After 3 hrs. at 0° and 12 hrs. at room temp. the benzene was distd. off and the residue in more benzene was again treated with CH_2N_2. The process was again repeated and the benzene-free product was shaken out with ether. The residue from the ether ext. was distd., yielding 90% (21 g.) of a light yellow, viscous oil, b_{12} 145–7°. Purification through the perchlorate gave a colorless oil, b_{12} 145°, of which 70 g. yielded 20 g. of prismatic crystals of a *neutral substance* (I), $C_{12}H_{18}O_2$, m. 55–6° (*perchlorate*, m. 90°; *oxime*, $C_{12}H_{19}NO_2$, m. about 195°), and a liquid crude product (II) which gives a yellow color with $C(NO_2)_4$, forms a white bisulfite addn. product, yields a white ppt. with $H_4Fe(CN)_6$, forms a solid bromide, and is changed by cold concd. HCl or warm dil. HCl or H_2SO_4 into an acid compd. (III). II (20 g.) was heated with 50 cc. of 10% HCl for 4 hrs. at 100° with frequent shaking. The cooled reaction mixt. was alkalinated and shaken out 5 times with ether. The ether-free aq. layer was acidified and the crude product was recrystd. from a benzene-petr. ether mixt. or H_2O, yielding fine colorless needles of III, $C_{11}H_{16}O_3$, m. about 220°, sol. in $NaHCO_3$, aq. soln. pH 4–5; *Ag salt*, light-sensitive; *phenylurethan*, $C_{18}H_{21}NO_3$, m. 91°; *bromide*, $C_{11}H_{15}BrO_3$, m. about 191°. Transformation of I into III by heating with 20% H_2SO_4 for 3 hrs. gave MeOH, identified as the 3,5-dinitrobenzoate, m. 109° (α-$C_{10}H_7NH_2$ addn. compd., m. 121°). Methylation of III with MeOH and concd. H_2SO_4, treatment of the product with $HClO_4$ and decompn. of the perchlorate gave I. Oxidation of III with CrO_3 produced camphoric acid. Catalytic hydrogenation of III in the presence of Ni at 70° and 120 atm. gave isoborneol whereas reduction with Na and alc. produced borneol and camphor glycol, m. 234° (bis(phenylurethan), $C_{24}H_{28}N_2O_4$, m. 171°). The oxidation and reduction products prove that III has an unaltered camphor structure. C. R. A.

Triterpene group. VI. The oxidation of β-amyrin benzoate. A new route to the thio compound $C_{30}H_{44}OS$. James C. E. Simpson. *J. Chem. Soc.* 1940, 230–7; cf. *C. A.* 33, 6326[7].—The oxidation of β-amyrin benzoate (I) is shown to be considerably more complex than would appear from the work of Beynon, Sharples and Spring (*C. A.* 32, 8407[4]) and in consequence cannot be regarded as comparable with oxidation of certain derivs. of β-boswellic acid (II), which give rise to single products in high yields (S. and Williams, *C. A.* 33, 553[7]). In view of this intrinsic dissimilarity and also in consequence of the work of Ruzicka, Müller and Schellenberg (*C. A.* 33, 6820[8]), the criticism of Spring as to the validity of the evidence on which the present tentative structure of II is based is no longer justifiable. I (10 g.) in 450 cc. glacial AcOH is treated under reflux with 7 g. CrO_3 in 30 cc. H_2O and 30 cc. AcOH added dropwise during 35–45 min.; after refluxing an addnl. hr. the product is pptd. with H_2O and crystd. from aq. AcOH, giving 50% of β-amyrenonyl benzoate (IIA), m. 255–60°; hydrolysis and acetylation give pure β-amyrenonyl acetate, m. 261.5–2.5°, $[\alpha]_D^{25}$ 96° ($CHCl_3$). The mother liquor from IIA is pptd. with H_2O and taken up in ether; 3% NaOH exts. an acid fraction (III); the neutral portion was refluxed for 6 hrs. with a large excess of 10% C_6H_6-EtOH-KOH and the resulting material acetylated, giving about 2% of an *acetate*, $C_{32}H_{50}O_4$, m. 322–4°, $[\alpha]_D^{25}$ −110° ($CHCl_3$, *c* 3.34); hydrolysis with 0.1 *N* EtOH-KOH in C_6H_6 gives the corresponding *alc.*, $C_{30}H_{48}O_3$, m. 284–5°; in another expt. the alc. m. 262–4°. This alc. does not react with EtOH-$FeCl_3$ or with *o*-$C_6H_4(NH_2)_2$ and since it does not contain an α,β-unsatd. ketonic group (absorption spectra) and shows little selective absorption in the ultraviolet, it is thought to be a ketonic oxide. III (20–5% of the total oxidation product), on methylation with CH_2N_2 and benzoylation, gives on crystn. from C_6H_6-EtOH a small quantity of a sparingly sol. *benzoate*, $C_{37}H_{50}O_4$, m. 293–4° (MeO-free) and a sol. *Me ether* (IV), $C_{48}H_{66}O_3$, m. 228–9°, $[\alpha]_D^{25}$ 16.7° ($CHCl_3$, *c* 3.62); IV does not react with $NH_2OH.AcOH$; the formula corresponds to the dibenzoate of an (enolized) hydroxy keto Me ester. β-Amyranonol yields a *benzoate* (V), m. 260.5–1.5°, $[\alpha]_D^{25}$ 7.3° ($CHCl_3$, *c* 2.21). β-Amyrenonol, on reduction and refluxing with its own wt. of fused AcONa in 9 parts of Ac_2O for 2.5 hrs., yields *dehydro-β-amyrenol* (VI), m. 209–11°, purified through the acetate (VII), m. 216–17°, $[\alpha]_D^{25}$ 3.9° ($CHCl_3$, *c* 1.88), gives an intense brown color with $C(NO_2)_4$ in $CHCl_3$. A 2nd prepn. of VII m. 221.5–3°, $[\alpha]_D^{25}$ 223° ($CHCl_3$, *c* 1.68), absorption max. 2820 A., log ϵ 3.76; hydrolysis yields a VI m. 195–7° (clears 208°). The phys. properties of VII appear to vary with small changes in exptl. conditions. VI yields a *benzoate* (VIII), m. 238–9°, $[\alpha]_D^{25}$ 219° ($CHCl_3$, *c* 2.21). Oxidation of VII with CrO_3 in aq. AcOH gives 25–30% of *β-amyradienone* (IX), $C_{30}H_{46}O$, m. 170–1°, $[\alpha]_D^{25}$ 108° ($CHCl_3$, *c* 1.2), shows selective absorption at 2540 and 2680 A., log ϵ 3.18, gives a deep yellow color with $C(NO_2)_4$ in $CHCl_3$ and a purple-crimson color with the Liebermann-Burchard



reagent. Another prepn. of **IX** m. 176.5–8°; its *oxime* m. 268.5–70° (decompn.). Refluxing **VIII** with S in $AcOCH_2Ph$ in N atm. for 3.5 hrs. gives the thio compd. $C_{30}H_{44}OS$ (**X**); **IIA** and **V** were recovered unchanged. A comparison of the behavior of **IX** with the 2 ketones from **X** leads to the conclusion that the chromophoric group in **X** and its derivs. cannot consist of a conjugated system of 2 double bonds. C. J. West

Triterpenes. LII. Conversion of α-boswellic acid into β-amyrin. L. Ruzicka and W. Wirz. *Helv. Chim. Acta* **23**, 132–5(1940); cf. *C. A.* **34**, 1642⁸.—The method used in the conversion of β-boswellic acid into α-amyrin (*C. A.* **33**, 8594⁹) has been extended to the α-boswellic acid (**I**) also found in olibanum. A mixt. of 5 g. of pure acetyl-α-boswellic acid and 30 g. $SOCl_2$ was kept overnight, freed from excess $SOCl_2$ and crystd. from hexane, yielding *acetyl-α-boswellyl chloride* (**II**), $C_{32}H_{49}ClO_3$, m. 195–6° (all m. ps. cor.). Reduction of 1 g. **II** in 10 cc. toluene by boiling in the presence of 1 g. Pd-$BaSO_4$ catalyst according to Rosenmund for 3 hrs. until 85% of the calcd. HCl was split off, filtration, concn. and recrystn. from hexane gave *acetyl-α-boswellaldehyde* (**III**), $C_{30}H_{50}O_3$, m. 203–6°, $[\alpha]_D$ 33.9° (*c* 1.87 in $CHCl_3$); *semicarbazone*, $C_{33}H_{53}N_3O_3$, m. 203–5°; *hydrazone* (**IV**), $C_{32}H_{52}N_2O_3$, m. 207–9°. Both **III** and **IV** give a yellow color with $C(NO_2)_4$. A mixt. of 900 mg. **IV** and 900 mg. $H_2NNH_2.H_2O$ was heated with 1 g. Na in 20 cc. abs. alc. in a sealed tube for 14 hrs. at 200°. The product was decompd. with H_2O, extd. with ether, taken up in petr. ether and filtered through a column of Al_2O_3. Elution with benzene gave 550 mg. of an as-yet *unknown product*, m. 224–5°, and further elution with ether yielded β-amyrin (**V**), $C_{30}H_{50}O$, m. 191–3°, $[\alpha]_D$ 91.3° (*c* 1.45 in $CHCl_3$) (Ac deriv., $C_{32}H_{52}O_2$, m. 242.0–2.5°; Bz deriv., $C_{37}H_{54}O_2$, m. 235.6°), identical with a pure sample from elemi resin. Further confirmation for the assignment of I to the β-amyrin type was provided by oxidation. I (1 g.) in 50 cc. AcOH was stirred with 500 mg. CrO_3 in 3 cc. H_2O and 15 cc. AcOH for 1 hr. and the mixt. was kept at 55–60° for another hr. The CrO_3 was eliminated with MeOH and the resulting keto acid was decarboxylated by boiling. The soln. was evapd. down, taken up in ether and the acid portion was sepd. out, yielding 780 mg. of neutral product, m. 188–94°, recrystd. 10 times from MeOH to a product, m. 217–20°. Chromatographing in petr. ether, elution with benzene in 5 fractions and a triple recrystn. of the last 2 fractions gave a *diketone*, $C_{29}H_{46}O_2$, m. 222–5°, $[\alpha]_D$ 7.6° (*c* 0.93 in $CHCl_3$), absorption max. at 2520 A. (characteristic for α,β-unsatd. ketones) identical with a diketone obtained by R. and Marxer from nor-β-amyrin, produced by the rearrangement of hederagenin. **LIII. Conversion of hederagenin into a rearrangement product of α-boswellic acid.** L. Ruzicka and A. Marxer. *Ibid.* 144–52.—According to similarities in structure and reactions the triterpenes are divisible into the 4 sub-groups: squalene, β-amyrin, α-amyrin and lupeol. These transformations are tabulated with the corresponding references. Wolff-Kishner reduction of the triterpene aldehydes converts glycyrrhetaldehyde to hydroxy-β-amyrin and oleanolaldehyde to erythrodiol. An analogous reduction of α-boswellaldehyde (**I**) should yield a diol, *hederadiol* (**II**), identical with that obtained from hederagenin by conversion of the CO_2H into a Me group. **II** is not identical with any of the known triterpene diols, of which a tabulation with m. p., sp. rotations and literature references is given. Treatment of diacetylhederagenin, m. 161°, with $SOCl_2$ and recrystn. of the product from hexane gave cryst. *diacetylhederagenin chloride* (**III**), $C_{34}H_{51}ClO_5$, m. 174°. Reduction of 500 mg. **III** in 2 cc. of xylene in the presence of 500 mg. of 5% Pd-$BaSO_4$ catalyst in 14 cc. xylene was carried out for 3 hrs. at 150° in a H atm. and with the addn. of 0.25 cc. of catalyst poison (1.2 g. quinoline and 0.2 g. S heated for 2 hrs. and taken up in 100 cc. xylene) until 80–90% of the calcd. amt. of HCl was evolved. After filtration and concn. the product was crystd. from pentane, yielding *diacetylhederaldehyde* (**IV**), $C_{34}H_{52}O_5$, m. 108–9°; *semicarbazone* (**V**), $C_{35}H_{55}N_3O_5$, m. 210–2°. **V** (2 g.) was reduced by heating for 20 hrs. with 2 g. Na in 40 cc. abs. alc. at 190–200° in sealed tubes. The cooled mixt. was poured into dil. HCl and extd. with ether. The crude product (1.6 g.) was taken up in benzene and chromatographed. Elution with a benzene-ether mixt. (1:1) dissolved the main amt. of (**VI**) (920 mg.) and a further elution with acetone gave 500 mg. of **II**, $C_{30}H_{50}O_2$, m. 259–61°, $[\alpha]_D$ 86.8° (*c* 1.012 in $CHCl_3$) (non-identical with soy sapogenol, erythrodiol, faradiol or hydroxy-β-amyrin); *di-Bz deriv.*, $C_{44}H_{58}O_4$, m. 186–8°, $[\alpha]_D$ 128.0° (*c* 1.015 in $CHCl_3$). CrO_3 oxidation of **II** (analogous to that of hederagenin to hederagone) gave a mixt. of oxidized compds. instead of a ketone identical with nor-β-boswellenone, $C_{29}H_{46}O$. **VI** was recrystd. from a $CHCl_3$-MeOH mixt. and yielded *nor-β-amyrin* (**VII**), $C_{29}H_{48}O$, m. 223–5°, $[\alpha]_D$ 118.2° (*c* 1.1015 in $CHCl_3$); *Ac deriv.*, $C_{31}H_{50}O_2$, m. 198°, $[\alpha]_D$ 113.5° (*c* 0.987 in $CHCl_3$). **VII** is satd. to Br and gives, as does its Ac deriv., the same yellow color with $C(NO_2)_4$ as **II**. **VII** (100 mg.) in 15 cc. AcOH and a few drops of $CHCl_3$ was oxidized with 100 mg. CrO_3 in 12 cc. AcOH at room temp. for 12 hrs. The product was worked up and sepd. into acid (10 mg.) and neutral (80 mg.) fractions. Recrystn. and chromatographic sepn. of the neutral fraction gave a diketone, $C_{29}H_{46}O_2$, m. 218–20°, $[\alpha]_D$ 8.0° (*c* 0.82 in $CHCl_3$), identical with the diketone from α-boswellic acid (cf. part LII, above). C. R. Addinall

Biphenyl series. V. Preparation of asymmetrical biaryl derivatives. Herbert H. Hodgson and Ewart Marsden. *J. Chem. Soc.* **1940**, 208–11; cf. *C. A.* **29**, 152⁴.—Diazonium salts stabilized by 1-$C_{10}H_7SO_3H$ (**I**), 1,5-$C_{10}H_6(SO_3H)_2$ (**II**) or $ZnCl_2$ have been decompd. in hydrocarbon and $PhNO_2$ suspensions in a manner analogous to the exisiting procedure for Na benzenediazotate and PhN(NO)Ac. The greater reactivity of $PhNO_2$, compared with C_6H_6, with respect to the diazotate as found by Grieve and Hey (*C. A.* **29**, 749³) has been confirmed for the stabilized diazonium salts. Decompns. of the stabilized salts by fused AcONa in conjunction with Ac_2O or glacial AcOH have afforded yields of biaryls amounting to 70% in some cases. The last-named processes appear to be far superior to the alk. decompn. of diazotates. The amine (0.1 g.-mol.) was diazotized at 0° in a mixt. of HCl (24 cc., d. 1.6) and 150 cc. H_2O and treated with finely powd. I (0.1 g.-mol.), **II** (0.2 g.-mol.) or anhyd. $ZnCl_2$ (0.1 g.-mol.). Some stabilized diazonium salt sepd. immediately but the mixt. was stirred for about 1 hr. to complete the pptn. $PhNH_2$ and α- and β-$C_{10}H_7NH_2$ did not give serviceable salts with I, since they sepd. as uncrystallizable oils. Diazotized $PhNH_2$ (**IV**), stabilized with **II**, decompd. in C_6H_6 at room temp. for 48 hrs. and then at 80° until N evolution ceases, gives 10.2, 10.2 and 7.6% Ph_2 with NaOH, KOH and Na_2CO_3; with $ZnCl_2$ as stabilizer the following yields (%) result: EtOH-KOH 14.6, NaOH 2.8, Na_2CO_3 9, Ac_2O and AcONa 20.2, AcOH and AcONa 12.3. The salt (10 g.) from α-$C_{10}H_7N_2Cl$ and **II** in AcOH and AcONa yields 3.3 g. $C_{10}H_8$ and 1.1 g. of α-$C_{10}H_7OH$ but no $(\alpha\text{-}C_{10}H_7)_2$. Using the stabilizers listed, the following products were obtained with Na_2CO_3 in C_6H_6: **IV** with **II**, 17% Ph_2, *o*-NO_2 deriv. of **IV** (**V**) with I, 35.2% of 2-$O_2NC_6H_4Ph$; *m*-isomer (**VI**) with I 54.4% of 3-$O_2NC_6H_4Ph$ (**VIA**); *p*-isomer (**VII**) with I 58.2% 4-$O_2NC_6H_4Ph$ (**VIII**); α-$C_{10}H_7N_2Cl$ (**IX**) with **II**, 15.2% of α-$C_{10}H_7Ph$; β-isomer (**X**) with **II**, no reaction. In $PhNO_2$ the following products were formed: **IV** 35.1% **VIII**; **VI** 48.7% of *3,4′-dinitrobiphenyl* (**XI**), pale yellow, m. 137°; **VII** 42.6% of $(4\text{-}O_2NC_6H_4)_2$ (**XII**); no reaction with **IX** or **X**. With fused AcONa and glacial AcOH in $PhNO_2$ **IV** gives 33% of **VIII**, **V** 30% of the 2,4′-isomer of **XI**, **VI** 54% of **XI** and **VII** 69% of **XII**; **IX** gives 38.8% of *1-nitro-4-phenylnaphthalene*, yellow, m. 151°; **IX** in C_6H_6 gives 17.3% of α-$C_{10}H_7Ph$ and **X** in C_6H_6 or $PhNO_2$ gives mixts. of azo compds. With fused AcONa and Ac_2O in C_6H_6 **IV** gives 46.6% Ph_2, **VI** 55.6% of **VIA**, (in $PhNO_2$ 54% of **XI**), **VII** 57.4% of **VIII**, **IX** 30.3% α-$C_{10}H_7Ph$ and **IX** in $PhNO_2$ or **X** in C_6H_6 give mixts. contg. azo compds. Using $ZnCl_2$ as the stabilizer **IV** gives 17.6% Ph_2, **VII** gives 37.2% **VIII**, *p*-$ClC_6H_4N_2Cl$ gives 34.2%

4-ClC$_6$H$_4$Ph and p-MeOC$_6$H$_4$N$_2$X gives 26.5% 4-MeOC$_6$H$_4$Ph. Decompn. of p-O$_2$NC$_6$H$_4$N$_2$X with 30% EtOH-KOH or with fused AcONa and Ac$_2$O gives with the use of I 25.1 and 50.4% VIII, with II 39.6 and 70.2% and with ZnCl$_2$ 16.4 and 26.3%. IV in PhMe with AcONa and Ac$_2$O gives no biaryl but with Na$_2$CO$_3$ it yields a small quantity of 4-MeC$_6$H$_4$Ph. C. J. West 1

Chemistry of β-arylglutaconic acids. V. α,γ-C-Diacetylation of β-arylglutaconic anhydrides. Synthesis of biphenyl derivatives. G. R. Gogte. *J. Univ. Bombay* **8**, Pt. 3, 208–19(1939); cf. *C. A.* **33**, 5389[3].—In earlier work it was found that α-*C*-acetyl-β-arylglutaconic anhydrides (I) could be further acetylated, giving products which were considered to be neutral *O*-Ac derivs. These more highly acetylated compds. (II) titrated as strong monobasic acids and gave pronounced colors with FeCl$_3$. It is proved in the present paper that II are α,γ-*C*-diacetyl-β-arylglutaconic anhydrides. α-Aceto-β-(4-methoxyphenyl)glutaconic anhydride (III), m. 132°, gives on further acetylation *α,γ-diaceto-β-(4-methoxyphenyl)glutaconic anhydride* (IV), m. 108°. IV is also obtained by direct acetylation of β-(4-methoxyphenyl)glutaconic acid. IV gives a violet color with FeCl$_3$ and an insol. *Na salt*. Its *PhNH$_3$ salt* m. 144° and gives a blue color with FeCl$_3$; it dissolves in cold Na$_2$CO$_3$ soln. and decomps. immediately to PhNH$_2$ and IV. When steam-distd. with dil. HCl, IV gives β-(4-methoxyphenyl)propylene, and, when refluxed with concd. HCl, a *lactone*, m. 112°. In these reactions 1 AcO group is removed with the formation of III. When 5 g. IV is heated with 50 cc. 10% NaOH soln. for 15 min. and acidified, a ppt. seps. after 2 hrs. This is treated with 10% Na$_2$CO$_3$ soln. from which, on cooling, *4'-methoxy-5-methyl-3-hydroxybiphenyl* (V), m. 118°, seps. Its *Bz deriv.* m. 120°. From the Na$_2$CO$_3$ soln. on acidification *4'-methoxy-5-methyl-3-hydroxybiphenyl-2-carboxylic acid* (VI), m. 182° (decompn.), is obtained. On refluxing with dil. HCl for 3 hrs. it is converted into V. V is also obtained by oxidation of 3-methyl-5-(*p*-methoxyphenyl)-2-cyclohexen-1-one with FeCl$_3$ according to Rabe and Pollock (*C. A.* **7**, 999); this fixes the constitution of V. When VI is heated at 200° and 40 mm. a compd. (VII), m. 119°, is formed which gives a green color with FeCl$_3$ and on refluxing with 10% NaOH dissolves and is converted into V and VI. VII therefore is an ester 2 3 4 5 6

(R = p-MeOC$_6$H$_4$), of VI and V.

Acetylation of β-(2-methoxy-5-methylphenyl)glutaconic anhydride gives *α,β-diaceto-β-(2-methoxy-5-methylphenyl) glutaconic anhydride* (VIII), m. 168°. It gives a violet color with FeCl$_3$ and on refluxing with concd. HCl for 3 hrs. 2-methoxy-5-methyl-β-acetonylcinnamic acid, m. 101°, is formed. When VIII is refluxed with 10% NaOH *2'-methoxy-5,5'-dimethyl-3-hydroxybiphenyl* (IX), m. 85°, is formed. Its *Ac deriv.* b$_6$ 181–5°. In addn. to this, *2'-methoxy-5,5'-dimethyl-3-hydroxybiphenyl-2-carboxylic acid* (X), m. 213° (decompn.), and *2'-methoxy-3,5'-dimethyl-5-hydroxybiphenyl-2-carboxylic acid* (XI), m. 192° (decompn.), are formed. X gives an *Ac deriv.*, m. 161°, and on thermal decompn. at 200° and 35 mm., IX and an *ester* corresponding to VII, m. 127°. This ester is decompd. by alkali into X and IX. XI gives a deep violet color with FeCl$_3$ and loses CO$_2$ on refluxing with mineral acids, giving IX. When X is dissolved in concd. H$_2$SO$_4$ and kept at 70° for 1 hr. *3,8-dimethyl-5-methoxy-3-hydroxyfluorenone* (XII), m. 168°, is formed in addn. to the lactone (XIII) of X, m. 194°. When XIII is refluxed with 20% NaOH and the alkali soln. treated with an excess of Me$_2$SO$_4$ at 100° and acidified, X is formed. The *Ac deriv.* of XIII m. 163°, the *Ac deriv.* of XII m. 191°. When XI is treated with H$_2$SO$_4$, *1,8-dimethyl-5-methoxy-3-hydroxyfluorenone*, m. 264°, is formed; its *Ac deriv.* m. 172°. Acetylation of β-(4-methoxy-3-methylphenyl)glutaconic acid with Ac$_2$O and AcONa gives the *α,γ-C-diacetylated* deriv. (XIV), m. 158° (decompn.), which gives a violet color with FeCl$_3$ and dissolves in cold dil. alkali. When XIV is treated with 10% NaOH, *3',5-dimethyl-4'-methoxy-3-hydroxybiphenyl* (XV), m. 69°, and *3',5-dimethyl-4'-methoxy-3-hydroxybiphenyl-2-carboxylic acid* (XVI), m. 172° (decompn.), are formed. Decarboxylation of XVI by mineral acids or heat gives XV, and its *ester* with XV m. 108°. F. E. Brauns 7 8 9

Formation of ketyls by the action of potassium on benzopinacol. Tudor John and Sydney T. Bowden. *J. Chem. Soc.* **1940**, 251–2.—Benzopinacol (I) (5.3 g.) in xylene, treated under N with K, gives the blue ketyl; on heating to the m. p. of the metal there is a vigorous evolution of H and the soln. changes in color from green to blue; K benzohydryloxide (II) is pptd. and if the soln. is cooled the color sequence is reversed; hydrolysis gives 4.2 g. benzohydrol (III) and 0.2 g. of Ph$_2$CO (IV). An equimol. mixt. of 2.7 g. III and 2.6 g. IV behaves in similar manner with K and the products of hydrolysis are 4.6 g. III and 0.2 g. IV. K reacts slowly with IV and only 30% of the metal forms the ketyl after boiling 5 hrs. The hydroxyl H of I is directly replaced by metal with the formation of mono- and di-K derivs.; the latter suffers partial dissocn. to the unimol. ketyl and is then reduced to II. I reacts almost instantly in the cold with Ph$_3$COK to form the ketyl system and Ph$_3$COH. C. J. West

Free radicals and radical stability. VII. The influence of the phenoxy group on the stability of ketylic derivatives. The preparation of carbon monoxide from carbonates. Sydney T. Bowden and Tudor John. *J. Chem. Soc.* **1940**, 213–16; cf. *C. A.* **33**, 3364[5].—CO is evolved when Ph$_2$CO$_3$ is treated with metallic Na. The only other product is PhONa and the over-all reaction may be represented as Ph$_2$CO$_3$ + 2Na = 2PhONa + CO. The gas is 100% pure and since it is formed in a system contg. free Na, it does not explode when sparked with dry O. The reaction thus furnishes a convenient and rapid method of prepg. CO in a sufficiently dry condition for demonstrating the catalytic effect of moisture on combustion. The mechanism of the reaction is briefly discussed. The absence of color in the reaction mixt. and the fact that a similar reaction occurs with aliphatic derivs. such as Et$_2$CO$_3$ would seem to point to simple scission of the carbonate. If, however, the reaction actually involves the ketyl mechanism, as found in the case of other esters, then the ketyl system formed from the carbonate must either be colorless or suffer rapid transformation into a colorless intermediate which subsequently eliminates Na alkoxide or aryloxide. The formation of Na triphenylmethoxide through the condensation of Et$_2$CO$_3$ and PhCl in the presence of Na is readily explained on the basis of the ketyl mechanism. C. J. West 10

Enediols. III. 1,2-Dimesitylacetylene glycol. Reynold C. Fuson, C. H. McKeever and Joseph Corse. *J. Am. Chem. Soc.* **62**, 600–2(1940); cf. *C. A.* **33**, 7756[2].—Exptl. details are given of the work reported in *C. A.* **33**, 4228[9]. (2,4,6-Me$_3$C$_6$H$_2$C(OH):)$_2$ (I) is prepd. in 35% yield by the action of Mg + MgI$_2$ upon 2,4,6-Me$_3$C$_6$H$_2$COCl or in 60% yield with mesitil; hydrogenation of mesitil gives 85–95% of I. Refluxing 1.3 g. of I and 6 cc. MeOH-HCl for 45 min. gives 1.2 g. of mesitoin (*acetate* (II), m. 106–7°). I and Ac$_2$O, refluxed for 3 hrs., give the *di-Ac deriv.*, one of which is insol. in MeOH (III), m. 218°; the other (IV), m. 164–5°, crystallizes from the MeOH at room temp.; other products are II and mesitil; the I obtained by reduction of mesitil gives 20–30% of III and a trace or none of IV, a good yield of II and a small amt. of mesitil; if mesitil is reduced in Ac$_2$O 90% of IV is obtained; I and AcCl give 70–80% of II. I and BzCl in C$_5$H$_5$N give the di-Bz deriv., m. 188.5–9.5° (V); a 2nd di-Bz deriv. could not be found; the I prepd. by catalytic reduction in MeOH yields the di-Bz deriv. m. 235° and V. C. J. West 11

A *p,p'*-biradical of biphenyl of the triphenylmethyl type. I. Walter Theilacker and Werner Ozegowski. *Ber.* **73B**, 33–43(1940).—It has been found (*Angew. Chem.* **52**, 373(1939)) in the study of substituted benzidines that N-

contg. derivs. of diphenoquinone, O:C_6H_4:C_6H_4:O (I), are not formed when there are substituents in the *o*-positions to the central union between the benzene rings; apparently the coplanar position of the 2 rings is disturbed by the spatial influence of the substituents so that a planar arrangement of the substituents about a C:C bond between the rings is impossible and the double bond is not formed. To prevent the formation of the I grouping all 4 of the *o*-positions to the central union need not be substituted; 2 relatively small substituents (e. g., Me) suffice. As the 2,2'-derivs. are readily available, they afford a simple means of investigating chemically a no. of problems involving the question of quinoid and nonquinoid structure. The Chichibabin hydrocarbons (II) (*C. A.* 1, 2103), for which a quinoid formulation, Ph_2C:C_6H_4:C_6H_4:CPh_2, is possible, has, because of its sensitivity to O, often been considered to be a biradical, $Ph_2CC_6H_4$-$C_6H_4CPh_2$, but its quinoid structure has been established by magnetic and electron-affinity studies (Müller and Müller-Rodloff, *C. A.* 29, 5320[6]; Bent and Gould, *C. A.* 29, 6234[8]). If substituents are introduced into II in the *o*-positions to the central union, the quinoid structure becomes impossible and it should be possible to isolate the true biradical. To secure the most exact possible comparison of the phys. and chem. properties of the expected biradical with those of II, the 2,2'-di-Me compd. was chosen because the introduction of a Me group into the nucleus of an aromatic compd. hardly alters the properties of the latter. *m*-Tolidine was converted by the Sandmeyer reaction into *2,2'-dimethyl-4,4'-dicyanobiphenyl* (21% yield), b_2 176°, m. 113°, which was hydrolyzed with boiling H_2SO_4 (3 vols. concd. acid +2 vols. water) to the *dicarboxylic acid* (94% yield), m. 326°. The *di-Et ester* (III) (79% from the acid with alc. and dry HCl), b_2 220°, m. 70°, with 8 mols. of PhMgBr gave 96% of *2,2'-dimethyl-4,4'-bis(diphenylhydroxymethyl)biphenyl* (IV). The purification of IV offered some difficulty and was best effected through the *di-Et ether* (V) (82%, based on III, from IV with hot 6% alc. HCl), m. 199 200°. IV forms a 1:1 *AcOH compd.*, m. 121° on rapid heating, resolidifies and m. again 173°, and a 2:1 *AcOEt compd.*, m. 136°, resolidifies and m. again 172°. Like [*p*-Ph_2C-(OH)C_6H_4]$_2$, IV shows with $SnCl_4$, $SbCl_5$ and $ZnCl_2$ the typical halochromic phenomena of triarylmethanols. IV and V with HCl in AcOH readily form the *dichloride* (VII), m. 210°, which, when shaken in benzene under CO_2 with Hg at room temp., reacts readily with the metal, and filtration gives a deep red-brown soln. with the characteristic properties of radical solns. Addn. of much petr. ether ppts. a greenish yellow product which is washed with petr. ether, dried at about 50° in air-free CO_2 and repeatedly repptd. from benzene with petr. ether. The *2,2'-dimethyl-4,4'-bis(diphenylmethyl)biphenyl* (VIII) thus obtained forms not a colorless but a faintly yellowish green powder, m. 176–8° to viscous red-brown droplets which begin to flow only above 200°. It becomes strongly electrified on rubbing and shows striking colors in soln. A very dil. (0.01%) soln. in benzene is bluish green, changing with increasing concn. to yellow-green and then becoming dichroic (green in transmitted, red-brown in incident light) and finally (at about 5% concn.) deep brown-red. In benzene-ligroin (1:5), in which it is but little sol., very dil. solns. are dichroic (green with reddish shimmer, brownish lilac). All solns. are sensitive to light and show brown-yellow fluorescence in ultraviolet light. Even to the naked eye dil. solns. of VIII (green) appear markedly different from the violet solns. of II. The spectroscope brings out these differences even more distinctly; VIII shows a relatively narrow band in the yellow and then absorbs from the blue-green toward the shorter wave lengths, while II shows only a broad band extending from the orange-red to the blue. The corresponding glycols in concd. H_2SO_4, on the other hand, show an extraordinary similarity. The magnetic method not being available for obtaining decisive confirmation of the radical nature of VIII, other means were resorted to. 1 VIII, both in soln. and in the solid state, is exceedingly sensitive to O. In the air the faintly yellow-green VIII instantly changes to a faint yellow (peroxide formation). When air is passed through the deep red-brown benzene soln. (about 5%) a short time, the soln. becomes light yellow but red-brown streamers appear rapidly and the soln. again becomes red-brown; the expt. can be repeated 8–10 times until the radical is completely oxidized. The 2 adsorption band in the yellow changes correspondingly; it disappears when the soln. becomes light yellow and reappears as the brown color is restored. The *peroxide* is an amorphous, very faintly yellow powder, softens 152–3°, decompg. on further heating, sol. in benzene with light yellow color. The same conclusions as to the radical nature of VIII can be drawn from the behavior of its solns. on heating and cooling. The properties of VIII agree closely with those of the analogous biradical 3 with 4 Cl atoms in the *o*-positions described by Müller and Neuhoff (*Ber.* 72B, 2063 (1939)), but T. and O. interpret the exptl. data differently. The assocn. of triarylmethyls occurs most simply by dimerization, whereby 2 of the radicals mutually sat. each other's free valences to form a hexaarylethane. In a biradical the mutual satn. of the free valences may be intramol. or, if this is not possible because of spatial effects, intermol., involving several mols. If the Ph_2 mol. is assumed to be 4 rigidly linear, assocn. of 2 mols. VIII to a cyclic dimer would require a 20° distortion of each of the 2 free valences or of the central union between the 2 benzene rings. The smallest strainless ring which could be formed from such radicals would be one made up of 3 radicals. It is a quite general fact, however, that the formation of such multimembered rings is never quant.; there are always formed polymeric compds., which may become the main 5 products if the reaction is not effected in extremely dil. soln. This is also undoubtedly the case with VIII. Since its assocn. increases with increasing concn. but there is still a radical equil. in the more concd. solns. it is highly probable that even if cyclic systems are formed in very dil. soln. they change with increasing concn., by chain-like combination, into polymers which are still radicals in that they have free valences at the ends of the chains. The conditions are much more complex than in the case of 6 simple radicals of the triarylmethyl series and the content of monomeric radical can no longer be detd. by mol. wt. detns., magnetic measurements, etc. C. A. R.

Tetraarylmethanes and their decomposition by the action of a liquid alloy of potassium and sodium. P. P. Shorygin and I. V. Machinskaya. *J. Gen. Chem.* (U. S. S. R.) 9, 1546–58 (1939).—The generally accepted explanation of the existence of free Ph_3C is that the affinities of the 7 central C atom are exhausted by the 3 Ph groups to such an extent that it is incapable of forming $(Ph_3C)_2$. Huckel (*Theoretische Grundlagen der org. Chemie*, 2, p. 312, *C. A.* 25, 3357) refutes this theory because it does not make clear the ability of greatly weakened C valency in Ph_3C to combine with an addnl. Ph group to form the stable Ph_4C, b. 413° without decompn. Sh. and M. do not see a contradiction in this with the instability of $(Ph_3C)_2$ and its dissocn. into Ph_3C, because the aggregate valency of the 8 central C atom in Ph_4C is distributed uniformly between the like Ph groups and therefore the sym. hydrocarbon does not tend to dissoc. into the radicals Ph_3C and Ph. Hence it could be postulated that derivs. of Ph_4C in which the sym. structure is disturbed would tend to dissoc. This could be possibly demonstrated by comparing the relative stability to dissocn. or cleavage of Ph_4C and its asym. derivs., such as *p*-benzohydryltetraphenylmethane, $Ph_2CHC_6H_4CPh_3$ (I). Ph_4C and I failed to dissoc. on boiling 9 in EtOBz and tetralin (cf. Schlenk and Herzenstein, *C. A.* 5, 1104). I is also stable to the action of Na in liquid NH_3 (cf. *C. A.* 31, 5777[8]). A complete cleavage was effected by the method of Ziegler and Thielmann (*C. A.* 18, 252) by mech. shaking of I and Ph_4C in ether with K-Na in a N atm. for 34–100 hrs. Among the decompn. products of I were identified 2-benzylcyclohexene (II), b. 235–40°, probably a mixt. with the 3-isomer, and a new compd., *dihydrotetraphenylmethane*, $Ph_3CC_6H_7$, m.

168.5–9.5°. Ph_4C gave **II**, Ph_3CH_3, Ph_3CH and a few drops of C_6H_6, contg. probably some dihydrobenzene. The probable scheme of the complex reaction is tautomerization of Ph_4C and I with the addn. of K at the double bonds and cleavage of the hydrocarbon chains (cf. Shorygin, *C. A.* **21**, 579). 40 references. Chas. Blanc

The isomeric *p,p'*-dihydroxy-3,4-diphenyl-*n*-hexenes. F. Wessely and A. Kleedorfer. *Naturwissenschaften* **27**, 567–8(1939).—In the course of work on the products of dehydration of 3,4-dianisyl-3-hexanol there were prepd. 2 isomeric compds. of the constitution *p,p'*-$ROC_6H_4C(:CHMe)CHEtC_6H_4OR$. For the 2 isomers the consts. are, with R=H, m. 153° and 143.5°; with R=Ac, no m. p. (oily) and 74°; with R=Bz, m. 126° and 184°; with R=Me, m. 50° and oily. Both isomeric di-Me ethers (R=Me) are converted with I to the diethylstilbestrol di-Me ether, m. 127°. Catalytic hydrogenation (Pd) converts both compds. to 3,4-dianisylhexane, m. 146°, in 50–60% yield. The estrogenic activity of the HO compd. m. 143.5° is 100% estrus with 1000-γ dose; for that m. 153°, 100% for 2.5-γ dose. For the 2 isomeric *p,p'-dihydroxy-3,4-diphenylhexanes* the activity is 100-γ dose for the one m. 130°, 2-γ dose for the one m. 186° to give 100% estrus. B. J. C. van der Hoeven

Oximes of 4,4'-dinitrobenzil. Wanda Brydówna. *Roczniki Chem.* **18**, 396–403(1938).—$(p\text{-}NO_2C_6H_4CO)_2$ (I) heated with $NH_2OH.HCl$ and NaOAc in MeOH yields *α-4,4'-dinitrobenzilmonoxime* (II), m. 193–4° (decompn.) (*Cu*^{II}, *Co*^{II}, *Fe*^{II} *salts*), the *Ac deriv.*, m. 139–40°, of which with 1% NaOH yields *p*-$NO_2C_6H_4CN$ (III) and *p*-$NO_2C_6H_4CO_2H$ (IV). A mixt. of the *α*- and *β-monoxime* (V), m. 164–6° (*Ac deriv.*, m. 157–8°), is obtained from I and $NH_2OH.HCl$ in boiling EtOH. V is instantaneously converted by 1% NaOH into III and IV, and by heating at 165° into II. By the Beckmann rearrangement V yields *p-nitrobenzoylform-p'-nitroanilide*, *p*-$NO_2C_6H_4COCONHC_6H_4NO_2$-*p'*, m. 142–7° (*dioxime*, m. 251–3°), readily decomp. to yield IV and *p*-$NO_2C_6H_4NH_2$. II with PCl_5 in ether gives III, IV, and $(p\text{-}NO_2C_6H_4CO)_2NH$. I and excess of $NH_2OH.HCl$ with NaOAc in boiling EtOH (20 hrs.) afford the *α*-dioxime, m. 268–70° (decompn.) (*Ni*^{II}, *Co*^{II}, *Fe*^{II} *salts*); the *β-dioxime*, m. 245–6°, obtained similarly in absence of NaOAc, gives $(p\text{-}NO_2C_6H_4NHCO)_2$ by the Beckmann rearrangement. B. C. P. A.

Dicinnamoylmethane series. I. Synthesis of three isomeric dinitro derivatives. W. Lampe and Z. Maciorewicz. *Roczniki Chem.* **18**, 668–79(1938).—PhCH:CHCO$CHNaCO_2Et$ and *o*-$NO_2C_6H_4CH:CHCOCl$ (I) are condensed, and the product is heated to yield *Et o-nitrodicinnamoylacetate* (II), m. 119–20°, converted by autoclaving into *o-nitrodicinnamoylmethane*, m. 156.5–7.5°, and by heating with 60% AcOH into *Et o-nitrocinnamoylacetate*, m. 70°, an ether soln. of which with I and MgMeI yields *Et di-o-nitrocinnamoylacetate*, m. 181°, autoclaved as above, to yield *di-o-nitrocinnamoylmethane*, m. 210°. $CHNaAcCO_2Et$ (III) and *m*-$NO_2C_6H_4CH:CHCOCl$ give *Et m-nitrocinnamoylacetoacetate*, m. 116°, converted by hot AcOH into *Et m-nitrocinnamoylacetate*, m. 88–9°, from which *Et di-m-nitrocinnamoylacetate*, m. 208°, and *3,3'-di-m-nitrocinnamoylmethane* are prepd. as above. *Et p-nitrocinnamoylacetoacetate*, m. 118° [from III and *p*-$NO_2C_6H_4CH:CHCOCl$], autoclaved with H_2O yields *p-nitrocinnamoylacetone*, m. 154–5° (decompn.). *Et p-nitrodicinnamoylacetate*, m. 188.5–9.5°, is prepd. analogously to II, and similarly yields *p-nitrodicinnamoylmethane*, m. 185°, *Et p-nitrocinnamoylacetate*, m. 110–11° (decompn.), *Et p-dinitrocinnamoylacetate*, m. 196° (decompn.), and *di-p-nitrocinnamoylmethane*, m. 254–6°. 5-Nitrosalicylaldehyde and $CH_3(CO_2Et)_2$ in the presence of piperidine (90 min. at 100°) give *Et 6-nitrocoumarin-3-carboxylate*, m. 198–9.5°, hydrolyzed (10% NaOH) to the *acid*, m. 234.5°, the *chloride*, m. 171–2°, of which with cinnamoylacetone yields *6-nitro-3-cinnamoylacetylcoumarin*, m. 264–5° (decompn.). B. C. P. A.

Synthesis of hydroxy derivatives of dicinnamoylmethane. M. Trenknerówna. *Roczniki Chem.* **18**, 830–9 (1938).—Et *o*-carbomethoxyoxycinnamoylacetoacetate with boiling aq. AcOH yields *Et o-carbomethoxyoxycinnamoylacetate*, the *Cu salt*, m. 209°, of which with Mg-EtBr and *o*-carbomethoxyoxycinnamoyl chloride gives *Et di-o-carbomethoxyoxycinnamoylacetate*, m. 130–2°; this is autoclaved, to yield *di-o-carbomethoxyoxycinnamoylmethane*, m. 123–5°, hydrolyzed ($NaOH\text{-}COMe_2$) to *di-o-hydroxycinnamoylmethane*, m. 170°. *o-Hydroxy-*, m. 165–70° (decompn.), and *2,4,2',4'-tetrahydroxydicinnamoylmethane*, decompn. 123–5°, were prepd. analogously. The following intermediates were obtained: *Et 2-carbomethoxy-*, m. 121–3°, and *2,4,2',4'-tetracarbomethoxyoxydicinnamoylacetate*, m. 155°, *Et 2,4-dicarbomethoxyoxycinnamoylacetate*, m. 74° (*Cu salt*, m. 190°), and *2,4,2',4'-tetracarbomethoxyoxydicinnamoylmethane*, m. 147°. B. C. P. A.

α-Vinylnaphthalene. M. M. Koton. *J. Gen. Chem.* (U. S. S. R.) **9**, 1626–30(1939).—1-$C_{10}H_7CH:CH_2$ was prepd. by the method of Shoruigin and Shoruigina (*C. A.* **29**, 6885[6]) and polymerized without a catalyst at 50–250° for 48–408 hrs. and at 15–20° for 30–90 days. In their dielec. strength the polymers are comparable to styrene polymers, but are inferior in mech. strength. C. Blanc

Replacement of the diazo group by hydrogen. Herbert H. Hodgson and Ewart Marsden. *J. Chem. Soc.* 1940, 207–8.—Stabilized diazotized amines are prepd. by diazotizing 0.1 g.-mol. of the amine in HCl or H_2SO_4, the total vol. being kept at the min. and the soln. (filtered if necessary) is stirred into a paste of 0.1 g.-mol. of 1,5-$C_{10}H_6(SO_3H)_2$ in 60 cc. H_2O; the stabilized diazonium salt, which ppts. in about 30 min., is filtered and dried at 30–40° (yield usually exceeds 90%); a 2nd method consists in treating the diazotized amine with AcONa to remove the mineral acid and stirring the soln. into a paste of 0.1 g.-mol. of 2, 1-$HOC_{10}H_6SO_3H$; these products are often colored by a small quantity of dye but even when somewhat tarry they can be used in the deamination process. These stabilized diazotized amines are decompd. by suspending 20 g. of the dry salt in 80 cc. EtOH and gradually treating at room temp. with Zn dust (about 30 g.) until the initial vigorous evolution of N subsides; the yields in all cases are almost theoretical; with Zn and Me_2CO the yields are about 5% less. The action of Cu powder in EtOH is more sluggish than that of Zn and a temp. of 30–5° is necessary. MeOH, Et_2O, $PhNO_2$, C_6H_6, $CHCl_3$ and CCl_4 may also be used; the reaction is sluggish in the last 3 solvents and boiling is necessary for efficient decompn. Several amines have been tested by this method. The decompn. appears to be a simple exchange of the H from 1 of the SO_3H groups via the agency of the metal, since no AcOH could be detected when EtOH was used. The action of EtOH alone on the stabilized salt of α-$C_{10}H_7N_2X$ was to produce $C_{10}H_8$, AcH and a tar contg. α-$C_{10}H_7OEt$. C. J. West

The mechanism of catalytic phenylation and its inhibition by iron. Herbert H. Hodgson and Ewart Marsden. *J. Soc. Chem. Ind.* **58**, 290–2(1939); cf. *C. A.* **33**, 6826[8].—The phenylation of α-naphthylamine by $PhNH_2$ was carried out in the usual way, using various acids as catalysts. With HI as a catalyst, the yield was 94%; with H_2SO_4, 43%; and with HCl, 30%. With peri acid and $PhNH_2$, HI gave a yield of 83%, HCl 83%, and H_2SO_4 86%. These yields were reduced by decompn. of peri acid during the course of the reaction. Since the reaction is unimol., both in the presence and absence of catalysts, it seems that the velocity-detg. step is the decompn. of an intermediate; e. g., $C_{10}H_7NH_2.PhNH_2.HI \rightarrow C_{10}H_7NHPh + NH_3 + HI$. In the presence of dry Fe filings, no α-$C_{10}H_7NHPh$ is formed; likewise, none when the reactants were heated in an iron vessel with a polished interior. However, if the container was allowed to rust, good yields were obtained. The phenylation of peri acid also proceeded better in the presence of rust. Ordinary FeI_2, contg. more or less water of hydration, is an efficient catalyst, while anhyd. FeI_2 is inactive. J. H. Reedy

Octahydrodinaphthyline and octahydronaphthidine. G. D. Parker and G. N. Walton. *J. Chem. Soc.* 1940, 201–2.—Azonaphthalene (4 g.), suspended in a boiling soln. of 8.5 g. of KOH in 800 cc. MeOH, is reduced with Zn dust

(2 hrs. boiling); the boiling soln. was rapidly decanted into a mixt. of 95 cc. concd. HCl and 100 cc. H_2O, kept for 24 hrs. in a tightly corked flask and then poured into 4 l. H_2O; the colorless filtrate on neutralization with concd. KOH gives 3.2 g. of a mixt. of dinaphthyline (I) and naphthidine (II); this is sepd. by soln. in 50 cc. of 3% HCl at 70–80° in a N atm. and addn. of 50 cc. concd. HCl, giving 1.2 g. of II (as HCl salt); neutralization of the filtrate gives 1.8 g. I. Reduction of 1 g. of I in boiling AmOH with Na gives 0.53 g. of *ar-octahydro deriv.* (III), m. 213°; it is stable when dry but is oxidized slowly in moist air or in EtOH; III does not form a cryst. HCl salt. The yellow tetrazotized soln. yields a bright red azo compd. with alk. β-$C_{10}H_7OH$. III does not form an Ac or a Bz deriv.; the *bisphenylurethan* m. 168°. II yields an *ar-octahydro deriv.*, m. 50°; *di-Ac deriv.*, m. 317°. III in suspension in aq. EtOH (soln. in EtOH and pptn. with H_2O) with Me_2SO_4 and anhyd. K_2CO_3 gives the *tetra-Me deriv.* (IV), m. 154°. I yields a *tetra-Me deriv.* (V), m. 212°, which is reduced by Na in AmOH to IV. The tetra-Me deriv. of II could not be crystd.; MeI gives *hexamethylnaphthidineammonium diiodide*, m. 220° (decompn.). Neither IV nor V forms quaternary derivs. This work was intended as the 1st stage of an investigation of the effect of condensed rings on the resolvability and ease of racemization of certain biphenyl derivs.; it is now proposed to use a different series of substances for the investigation. C. J. West

Synthesis of substituted α-naphthoquinones. C. F. Koelsch and D. J. Byers. *J. Am. Chem. Soc.* **62**, 560–2 (1940).—*o*-$C_6H_4(CO_2Et)_2$ and Na at 115°, treated with $PrCO_2Et$ and heated 4 hrs., give 32% of 2-ethylindan-1,3-dione (I), b_7 135–40°, m. 53–5°; the Me (31%), Pr (17%) and Bu analogs (18%) were also prepd. Boiling 13.6 g. of I, 4,4 g. of KOH and 13 g. $BrCH_2CO_2Et$ in EtOH for 2.5 hrs. gives 68% of *Et 2-ethylindandionyl-2-acetate* (II), m. 77–8.5°; the *2-Me analog* (62%), m. 91–2° (Gheorgin, *C. A.* **31**, 391[1], gives a m. p. of 161–2°, possibility of a hydrolysis product); the 2-Pr and 2-Bu analogs are oils which were not purified. II (13.8 g.) in EtONa in EtOH in H atm., boiled 2 hrs. and acidified, gives 68% of *2-ethyl - 3 - carbethoxy - 1,4 - naphthohydroquinone* (III), m. 110.5–11°; the *2-Me* (62%), *2-Pr* (14%) and *2-Bu analogs* (24%) m. 100–1°, 125–6.5° and 98.5–100°, resp. Oxidation of III with CrO_3 in cold AcOH gives 88% of the yellow *2-ethyl-3-carbethoxy-1,4-naphthoquinone* (IV), m. 47.5–8°; the *2-Me analog* (92%) m. 99–100°. Alk. hydrolysis (1% NaOH) of IV gives 36% of *2-ethyl-3-hydroxy-1,4-naphthoquinone*, yellow, m. 137.5–8.5°; the Bu analog (55%) m. 100–1°. Heating IV with 5% NaOH for 2 hrs. in H atm. gives 77% of 2-ethylnaphthoquinone, yellow, m. 87–8°. This appears to be a general method for the prepn. of 1,4-naphthoquinones and hydroquinones which contain a hydrocarbon residue in position 2 and bear a H, a HO or a CO_2Et group in position 3. C. J. West

Reaction between dihydroanthracene and benzoquinone. E. I. Prokopets and A. V. Pavlenko. *J. Gen. Chem.* (U. S. S. R.) **9**, 1468–9 (1939).—Fries, Schilling and Littmann (*C. A.* **26**, 5944) proposed a method for the detn. of anthracene (I) in the presence of dihydroanthracene (II) in xylene based on the quant. sepn. of I by benzoquinone (III) as the insol. anthracenebenzoquinone (IV) and the inability of II to react with III (cf. Clar, *C. A.* **25**, 5159). It was found that the method is impractical because of the following reactions: (1) III is reduced by II to hydroquinone which reacts with excess III to form quinhydrone; (2) I, formed in the oxidation of II, reacts with III to give IV; (3) quinhydrone, forming an equil. system with III and hydroquinone, is decompd. by I with the formation of IV and hydroquinone. Chas. Blanc

New route to 9-alkyl- and 9-arylanthracenes. Charles K. Bradsher. *J. Am. Chem. Soc.* **62**, 486–8 (1940).—*o*-$NCC_6H_4CH_2Ph$ (I) was prepd. in 30–50% yields by the method of Bergmann (*C. A.* **33**, 4225[7]) and in 54% yield by heating *o*-$ClC_6H_4CH_2Ph$ with CuCN at 250° for 23 hrs. I and MeMgI in C_6H_5-Et$_2$O, refluxed overnight, give 72% of *o-benzylacetophenone* (II), b_5 167°, m. 49–50°. Refluxing 2 g. II, 20 cc. AcOH and 20 cc. 34% HBr for 4 days gives 80% of 9-methylanthracene, yellow, m. 80–1°. I and EtMgBr give 73% of *o-benzylpropiophenone*, yellow oil, b_5 156 (*phenylhydrazone*, m. 97–8°, decomps. on standing 2 days); heating with HBr in AcOH gives 69% of 9-ethylanthracene, yellow, m. 58–9°. I and PhMgBr give 82% of *o*-benzylbenzophenone, m. 50–2°; HBr in AcOH yields 75% of 9-phenylanthracene, fluorescent plates, m. 154–5°. The theory is presented that the cyclization involved is one characteristic of the β-(β-styryl)vinyl alc. system, PhC:CC:COH. This explains the slow rate at which the anthracene hydrocarbons are formed, since it would not be expected that *o*-benzylphenyl ketones would exist in the enolic form to any great extent. C. J. West

Photooxidizability of 1,2-cyclo-substituted diphenylanthracenes. Léon Velluz. *Bull. soc. chim.* **6**, 1541–8 (1939).—The heating of the photooxide of diphenylanthracene (I) liberates at least 95% of the O contained, whereas thermal decompn. of the photooxides of the diphenylnaphthacenes (II) takes place without liberation of O. A study has been made of the 1,2-cyclo-substituted diphenylanthracenes, 9,10-diphenyl-1,2-benzanthracene (III) and 9,10-diphenyl-1,2-tetrahydrobenzanthracene (IV), in which the meso summits belong partially to a benzanthracenic and partially to a benzophenanthrenic system. Cyclization of *o*-tetrahydronaphthoylbenzoic acid with H_2SO_4 contg. 25% of SO_3 gave a mixt. of 1,2- and 2,3-tetrahydrobenzanthraquinones, sepd. by crystn. from benzene and petr. ether, hot and cold ligroin, ether and benzene, yielding yellow needles of 1,2-tetrahydrobenzanthraquinone (V), m. 136°. Treatment of V with 5 parts of PhMgBr in cold benzene gave 40% of the glycol, *9,10 - diphenyl - 9,10 - dihydro - 9,10 - dihydroxy - 1,2-tetrahydrobenzanthracene* (VI), $C_{30}H_{26}O_2$, m. 222°. VI (0.2 g.) in 10 cc. AcOH was treated with 0.2 g. KI and 0.50 g. NaH_2PO_2 and boiled for 15 mins. The yellow cryst. ppt. formed on cooling was washed with AcOH, H_2O and alc., yielding 80% of a mixt. of hydrocarbons, $C_{30}H_{24}$, of which 80% (assumed to be IV) m. 224° and 20% m. 298°. Both compds. have similar ultraviolet absorption spectra and both undergo complete photooxidation to reversible oxidation compds. similarly to all aryl anthracenes previously studied. Dehydrogenation of V by heating with PbO at 320–30° for 15–20 mins., extn. with boiling xylene and recrystn. from AcOH gave 30% of fine yellow needles of 1,2-benzanthraquinone, $C_{18}H_{10}O_2$, m. 169°, converted by the action of PhMgBr into 9,10-diphenyl-9,10-dihydroxy - 9,10 - dihydro - 1,2 - benzanthracene, $C_{30}H_{22}O_2$, m. 249°. Reduction with KI in AcOH gave 70% of III, m. 196°, giving 20% of a photooxide which liberated 57% of O on thermal decompn. at 130°. Thus this angular benzanthracene is intermediate in its reversible oxidizability between the naphthacenes and anthracenes. C. R. Addinall

3,3-Diphenyl-1-hydrindone and 3,3-diphenylindandione. Synthesis of triphenylmethane-2-(α-oxocarboxylic) acid. Paul E. Gagnon, R. Hudon, I. Cantin and J. Ganas. *Trans. Roy. Soc. Can.* III, **33**, 47–58 (1939).—Condensation of Ph_3COH with $CH_2(CO_2Et)_2$ in the presence of Ac_2O, with subsequent elimination of H_2O and CO_2, gave 3,3-diphenyl-1-hydrindone (I) (cf. Hellerman, *C. A.* 21, 2670). Oxidation of 5 g. I by heating for 10 hrs. with 9 g. $KMnO_4$ and 3.5 g. KOH in 400 cc. H_2O gave 4 g. diphenylphthalide (II), m. 115–17° (alc.). Oxidation of 10 g. I by heating with 300 cc. HNO_3 (d. 1.2) gave a mixt. (III), m. 130–50°, contg. II, *3,3-diphenyl-2,2-dinitro-1-hydrindone* (IV) and 3,3-diphenylindandione (V). Sepn. of IV was accomplished by dissolving the mixt. in anhyd. C_5H_5N and satg. with NH_3, resulting in the formation of canary-yellow crystals, $C_{21}H_{17}O_3N_3$ (VI), m. 170–1° (with liberation of NH_3). A constitution analogous to a hydrate, with the NH_3 group attached to the $-C(NO_2)_2$ group was ascribed to VI, since it is sol. in cold water, and since IV is readily regenerated from it by dissolving in HCl or Ac_2O, or by heating. When purified by regeneration from VI, IV m. 190–2° (decompn.). Heating III in AcOH or (better) heating without solvent under reduced pres-

sure at 160° converted the IV in the mixt. to V, m. 152–3°. The identity of V with the substance obtained by Schönberg and Michaelis (*C. A.* **31**, 4293[1]) was established by detg. the m. p. of a mixt. of the 2. Heating V with concd. KOH, followed by diln. and acidification gave *triphenylmethane-2-(α-oxocarboxylic) acid*, (*o*-$Ph_2CHC_6H_4COCO_2H$) (VII), m. 224–6°; *Me ester*, m. 93–4°; *Et ester*, m. 69–70°; *hydrazone*, m. 205°. Oxidation of VII in alk. soln. with H_2O_2 gave triphenylmethane-2-carboxylic acid, m. 155–7°. Attempts to prepare derivs. of V in which both carbonyl groups participated were not successful, but the following derivs. were prepd.: *dichloride*, m. 134–5°; *dibromide*, m. 110–15°; *oxime*, m. 100–1°; *hydrazone*, m. 163–4°; *phenylhydrazone*, m. 186–8°; *p-nitrophenylhydrazone*, m. 348–40°; *2-o-aminophenylene deriv.*, m. 241–2°. The carbonyl in position 1 was regarded as the reactive group, since the dibromide had a different m. p. than 3,3-diphenyl-2,2-dibromo-1-hydrindone. W. Gordon Rose

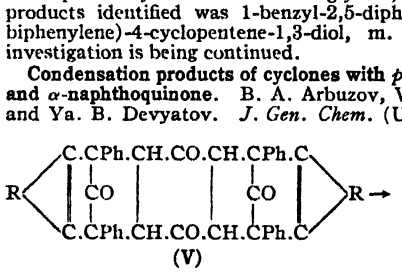
Dissociable organic oxides. Comparative oxidations of anthrahydroquinone and *meso*-dimethoxyanthracene. Influence of light. Charles Dufraisse and Robert Priou. *Bull. soc. chim.* **6**, 1649–56(1939).—The autoxidation of $C_6H_4[C(ONa)]_2C_6H_4$ (I) was studied in an all-glass app. in total darkness. Pure dry oxanthranol in a reaction flask contg. an open tube holding a slight excess of fused NaOH was treated with 25 cc. of distd. H_2O in a closed evacuated system which included a system for the introduction of a measured amt. of O. The reaction flask was covered with black paper and the remaining oxidation was carried out in a dark room. I was oxidized rapidly in total darkness and the oxidation was not increased by further illumination. The only product isolated was anthraquinone (II), without a trace of org. peroxide. The autoxidation of 9,10-dimethoxyanthracene (III) is extremely sensitive to light but does not take place in darkness. III was produced by treating 2.46 g. of *meso*-methoxyanthrone, m. 104–5°, in 245 cc. of 96% alc., at 70° in a H atm., with alternate addns. of 50% KOH and Me_2SO_4 until the addn. of alkali no longer produced a red color. Recrystn. of the product from benzene gave 60% of III, m. 202°. III (0.16 g.) in 400 cc. CS_2, distd. over Cu, was irradiated by sunlight with agitation in the air until the yellow color almost disappeared. The soln. was evapd. *in vacuo*, in total darkness, taken up in 50 cc. petr. ether, filtered and allowed to evap. in darkness, yielding 0.12 g. of *photoöxodimethoxyanthracene* (IV), $C_{16}H_{14}O_4$, m. 144–5° (decompn.), reduced quant. to II by KI in AcOH. Heating IV in the open gave an excellent yield of II. IV is extremely volatile but, in a sealed tube, the decompn. is complete at 180°, yielding only a small amt. of O and no CO_2, indicating a partial dissocn. of IV.
C. R. Addinall

A new method for the synthesis of amino carboxylic acids of the aromatic series. A. I. Kizber. *Compt. rend. acad. sci. U. R. S. S.* **24**, 440(1939)(in English).—Kolbe's reaction can be used to prep. 1- and 2-aminoanthraquinonecarboxylic acids, and 2-naphthylaminecarboxylic acid. S. Bradford Stone

β-Phenyl-β-(9-anthron-10-yl)propionic acids and their derivatives. Paul E. Gagnon and R. Hudon. *Trans. Roy. Soc. Canada* III, **33**, 37–46(1939).—The action of H_2SO_4 on β-phenyl-β-(9-anthron-10-yl)propionic acid (I), or of $AlCl_3$ on the acid chloride of I yields 3-(9-anthron-10-yl)-1-hydrindone whereas β-(3-nitrophenyl)-β-(9-anthron-10-yl)propionic acid (II), similarly treated, gave β-(3 - nitrophenyl) - β - (9 - hydroxy-9,10 - dihydro - 10-oxo-9-anthryl)propionic acid and the corresponding lactone (cf. *C. A.* **27**, 5321; Gravel, *C. A.* **28**, 169[6]; Vachon, *et al.*, *C. A.* **29**, 1087[8]; Kane, *C. A.* **29**, 3333[9]). Because of this difference in behavior, which was attributed to the presence of the nitro group, β-(4-nitrophenyl)-β-(9-anthron-10-yl)propionic acid was prepd. to compare its reactions with those of I and II. Condensation of 4-$NO_2C_6H_4CHO$ with $CH_2(CO_2Et)_2$ gave di-Et 4-nitrobenzylidenemalonate (68%) which was condensed with anthrone, using C_5H_5N as catalyst, giving β-(4-nitrophenyl)-β-(9-anthron-10-yl)isosuccinic acid (III) (89%); decarboxylation of III with H_2SO_4-AcOH gave β-(4-*nitrophenyl*)-β-(*9-anthron-10-yl*)*propionic acid* (IV). Heating 5 g. IV, 2.8 g. PCl_5 and 34 cc. CS_2 for 2 hrs. gave the *acid chloride* (V), m. 170–5°. The following derivs. of IV were prepd. from V: *amide* (93%), m. 225–7°; *anilide*, m. 110°; *Me ester*, m. 202–3°; *Et ester* (83%), m. 137–8°. To 200 cc. C_6H_6 and 14 g. V was added 6 g. $AlCl_3$ and the mixt. stirred 3 hrs. at room temp.; another 6 g. $AlCl_3$ was then added and stirring continued 3 hrs. longer. The reaction mixt. was then poured onto ice and HCl. The product (73%), m. 170–72°, was assigned the constitution *10-oxo-9-[α-(4-nitrophenyl)-β-benzoylethyl)-9,10-dihydroanthracene* (*oxime*, m. 187–8°). The corresponding *3-nitrophenyl compd.*, m. 174–6°, (oxime, m. 189–90°), was obtained (70%) by similar treatment of the acid chloride of II. No reaction occurred when $AlCl_3$ was added to V in CS_2, and the reaction mixt. heated to boiling for 5.5 hrs. Oxidation of 20.6 g. I with 6.8 g. $KMnO_4$ and 6.0 g. KOH in 1 l. H_2O, at room temp. for 24 hrs., gave β-phenyl-β-(10-hydroxy-9-anthron-10-yl)propionic acid, which was converted to a lactone (VI), m. 213–15°, when attempts were made to purify the HO acid by recrystn., or by heating. Further oxidation of the lactone with $KMnO_4$ gave BzOH and anthraquinone. A similar oxidation of IV gave 4-$NO_2C_6H_4CO_2H$ and anthraquinone directly; no HO acid or lactone could be isolated. No hydrindone or benzanthrone derivs. were obtained by the action of H_2SO_4 on IV. W. Gordon Rose

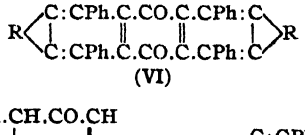
Bromination of anthraquinone-2-sulfamic acid. W. Leśniański and H. W. Turska-Jaroszewiczowa. *Roczniki Chem.* **18**, 680–7(1938).—Aq. Br is added in 10% excess to aq. Na anthraquinone-2-sulfamate at pH 6.5 (room temp.). Aq. Na_2CO_3 is added at intervals, to maintain the pH at 6.5, until free Br is no longer present, when the soln. is made feebly alk., boiled and then made strongly acid. The yield of 1-bromo-2-aminoanthraquinone is 83% on the aminoanthraquinone originally taken.
B. C. P. A.

New synthesis of phenanthrene derivatives. I. Phenanthrene-9,10-dicarboxylic anhydride and phenanthrene-9-carboxylic acid. T. A. Geissman and Roy W. Tess. *J. Am. Chem. Soc.* **62**, 514–16(1940).—Details are given of the synthesis of *o*-$PhC_6H_4CH_2NH_2$ (I) by heating 122.5 g. *o*-NCC_6H_4Ph, Raney Ni, 150 cc. liquid NH_3 and 50 cc. ether in a bomb under pressure of 3350 lb. H; upon heating to 120° the pressure rises to 4500 lb., then gradually falls to 1670 lb. in 4 hrs. I (12 g.) with $NaNO_2$ in AcOH gives 11.5 g. *o*-$PhC_6H_4CH_2OH$, b_{15} 177–84°, which was transformed into the chloride and then the cyanide (II). Refluxing 43.3 g. of II and 45 g. concd. H_2SO_4 in 55 g. 95% EtOH for 13 hrs. gives 55.2 g. of 2-$PhC_6H_4CH_2CO_2Et$ (III), b_{15} 180–5°. III (12 g.) and 7.5 g. $(CO_2Et)_2$ with EtOK in ether give the oxalyl ester, an oil; with 50 cc. AcOH and 30 cc. 48% HBr this yields 2.7 g. III and 7.95 g. of a pale yellow solid, contg. 67% of phenanthrene-9-carboxylic acid and 13% of phenanthrene-9,10-dicarboxylic anhydride, sepd. by recrystn. from Ac_2O. C. J. West



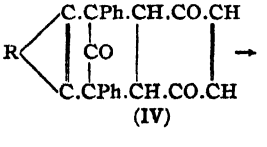
Catalytic transformation of dimeric 1,3-cyclohexadiene. E. V. Alekseevskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 1586–8(1939).—Kazanskiĭ and Vol'fson (*C. A.* **33**, 4966[8]) showed that dicyclohexadiene (I) is dehydrogenated over platinized charcoal at 240–5° to 1,4-endoethylenetetrahydronaphthalene, m. 63.5°. The expt. was repeated with dehydrogenation of I over reduced Pd at 320–80° by the method of Zelinskiĭ (*C. A.* **17**, 2567). The catalyzate gave a product, m. 62.5°, and another, m. 42–2.5°. The latter could not be obtained again. The cleavage of 2 mols. H from I could form 1,4-dimethyl-, 1-ethyl- and 1,4-endoethylenenaphthalene. In the hydrogenation of I in alc. in the presence of Pt black, it absorbed 2 mols. H to form *tetrahydrodicyclohexadiene* or *endoethylenedecahydronaphthalene*, $b_{7.5}$ 101.9°, d_4^{20} 0.9657, M. R.$_D$ 50.55, exaltation 0.48. Heating I and floridin at 232–360° gave mixed polymers, which are easily oxidized in air at room temp. Chas. Blanc

Synthesis of 6-hydroxy-3,4-benzopyrene and 8-isopropyl-1,2-benzanthracene from 9,10-dihydrophenanthrene. Louis F. Fieser and Wm. S. Johnson. *J. Am. Chem. Soc.* **62**, 575–7(1940).—4-Keto-1,2,3,4-tetrahydro-

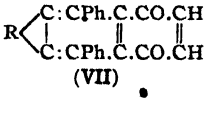


chrysene (I) (2 g.) and 1.2 g. $BrCH_2CO_2H$ with 4 g. activated Zn in 40 cc. C_6H_6, heated almost to boiling and a crystal of I introduced, react vigorously; after 1 hr. the Zn is completely coated with an oily complex; the mixt. is cooled, MeOH added to dissolve the oil, the soln. is decanted from the Zn, shaken with 10% HCl, H_2O and satd. NaCl soln. and filtered through Na_2SO_4. After removal of the solvent, the residual oil is boiled for 15 min. with excess *N* EtOH-KOH; addn. of H_2O and cooling gives 1 g. unchanged I; acidification of the alk. liquor gives 1.1 g. (94% based on reacting I) of crude *4-chryseneacetic acid* (II). Crude II (1.7 g.) in 250 cc. MeOH is satd. in the cold with HCl, refluxed for 12 hrs., dild. and extd. with Et_2O, giving 1.44 g. of the ester; this was heated with 0.18 g. S for 2 hrs. at 210° and after heating with a pinch of Zn for 5 min., distn. and crystn. from Me_2CO-MeOH gave 0.59 g. pure *Me ester*, m. 109–10°; hydrolysis yields 0.34 g. pure II, m. 207–8° (this is 20% on the basis of crude II). Cyclization of II with HF gives 57% of *6-hydroxy-3,4-benzopyrene*, light yellow, m. 195–6° (decompn.); it yields a red azo compd. with *p*-$O_2NC_6H_4N_2X$ and a red color with concd. H_2SO_4 which with HNO_3 gives a transient green and then a deep blue color. 8-Keto-3,4,5,6,7,8-hexahydro-1,2-benzanthracene (III) (3 g.) and iso-PrMgBr, refluxed 2 hrs., the product dehydrated at 220°, distd. and treated with petr. ether, give 0.73 g. unchanged III and 1.83 g. (73.5%) of an oil; heating the oil with S at 205–50° for 45 min. gives 35% of the *picrate* (IV), red, m. 155.5-6.5°, of *8-isopropyl-1,2-benzanthracene*, yellow, m. 97–8°. IV is decompd. by filtration of a C_6H_6 soln. through Al_2O_3. All m. ps. are cor. C. J. West

Reaction of phencyclone with organomagnesium halides. V. S. Abramov and P. G. Mal'skiĭ. *J. Gen. Chem.* (U. S. S. R.) 9, 1533-6(1939).—2,5-Diphenyl-3,4-(*o,o'*-biphenylene)-2,4-cyclopentadien-1-one was prepd. by condensation of phenanthraquinone and $(PhCH_2)_2CO$ in hot EtOH-KOH (cf. Dilthey, *et al.*, *C. A.* 29, 7323[1]). When treated with RMgBr in ether by the method of Ziegler and Schnell (*C. A.* 20, 383), it formed the corresponding 1-aryl- and 1-alkyl-1-methanols in 53–75% yield. R = Ph (from PhMgBr), m. 255–7°; Et (from EtMgBr), m. 179–80°; Bu (from BuMgBr), m. 237–9°; $PhCH_2$ (from $PhCH_2MgBr$), m. 264–5°. The condensation is accompanied by formation of some glycols; one of the by-products identified was 1-benzyl-2,5-diphenyl-3,4-(*o,o'*-biphenylene)-4-cyclopentene-1,3-diol, m. 158–9°. The investigation is being continued. Chas. Blanc



Condensation products of cyclones with *p*-benzoquinone and α-naphthoquinone. B. A. Arbuzov, V. S. Abramov and Ya. B. Devyatov. *J. Gen. Chem.* (U. S. S. R.) 9,



(V)

(VI)

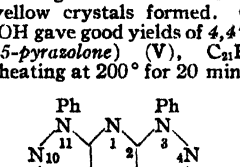
(IV)

(VII)

1559–63(1939).—Dilthey and co-workers (*C. A.* 31, 2197[1]; 32, 140[6]) produced highly arylated compds. from cyclones by diene synthesis. It was expected that *p*-quinones would react similarly with cyclones to form corresponding anthraquinone and naphthoquinone derivs. Attempts to obtain the products of addn. of α-naphthoquinone (I) and *p*-benzoquinone (II) to cyclone and acecyclone gave neg. results. The components either failed to react or under more drastic conditions of condensation were resinified. The reaction with phencyclone (III) gave expected results. Condensation of 2.1 g. I and 5 g. III in 40 ml. $PhNO_2$ on a water bath for 4 hrs. and at room temp. for 12–14 hrr. gave 73% of *1,4-endocarbonyl-2,3-(o,o'-biphenylene)-1,4-diphenyl-11,12-dihydroanthraquinone*, colorless crystals, m. 265–7°. Dehydrogenation with cleavage of the endo-CO group in boiling $PhNO_2$ gave 85% of *1,4-diphenyl-2,3-(o,o'-biphenylene)anthraquinone*, yellow, m. 359°. Condensation of equivs. of II and III as above gave *1,4-endocarbonyl-2,3-(o,o'-biphenylene)-9,10-dihydronaphthoquinone* (IV, R = —$C_6H_4.C_6H_4$—), m. 194°. If 2 mols. III to 1 mol. II are used the condensation products are 50% of the *diendocarbonyl deriv.* (V), m. 310°, and IV. Decompn. of V in $PhNO_2$ gave *1,4,5,8-tetraphenyl-2,3,6,7-bis-o,o'-biphenylene)anthraquinone*, (VI), m. 460–1°. The decompn. of IV gave VII, brown, m. 405–8°. Chas. Blanc

Dibenzofuran. XVIII. Isomeric metalation products of some phenols and their methyl ethers. Henry Gilman, H. B. Willis, T. H. Cook, F. J. Webb and R. N. Meals. *J. Am. Chem. Soc.* 62, 667-9(1940); cf. *C. A.* 34, 2369[9].—Metalation by BuLi of 2-methoxydibenzofuran gives 2-methoxy-1- and -3-dibenzofuryllithium, and 4-methoxydibenzofuran gives 4-methoxy-6- and -3-dibenzofuryllithium. However, metalation of the corresponding phenols gives but 1 product in each case: 2-hydroxydibenzofuran gives 2-hydroxy-1-dibenzofuryllithium and 4-hydroxydibenzofuran gives 4-hydroxy-6-dibenzofuryllithium. In contrast, metalation of *m*-$C_6H_4(OMe)_2$ gives apparently but 1 product (2,6-dimethoxyphenyllithium), whereas *m*-$C_6H_4(OH)_2$ gives the 2 isomers, 2,6- and 2,4-dihydroxyphenyllithium. *4-Methoxy-3-dibenzofurancarboxylic acid* (I), m. 182–3°; this also results by $KMnO_4$ oxidation of 3-acetyl-4-methoxydibenzofuran; the *6-isomer* of I m. 240–2° (*Me ester*). C. J. West

The reactions between thiophene and calcium hypochlorite solutions. E. G. R. Ardagh, W. H. Bowman and A. S. Weatherburn. *J. Soc. Chem. Ind.* 58, 249-51 (1939); cf. *C. A.* 29, 6888[8].—The reaction was studied over the pH range 4.1–8.0. At the higher pH values in the presence of a large excess HOCl nearly 90% of the thiophene S was oxidized to SO_4 ion. R. E. Reeves



Constituents of derris root. III. Th. M. Meyer. *Rec. trav. chim.* 58, 1119-23(1939) (in English); cf. *C. A.* 33, 8613[4].—Addnl. evidence for the structure of derride (I) has been obtained. A mixt. of 5 g. I, 50 cc. of 10% KOH and 70 cc. alc. was refluxed for 4 hrs. in a N atm.; the dild. reaction mixt. was acidified with HCl and extd. with ether. The ext. was shaken out with 10% $NaHCO_3$ and 5% KOH. The $NaHCO_3$ ext. was acidified with dil. H_2SO_4 and extd. with ether, yielding 0.8411 g. of residue. Distn. at 110–20° and 0.001 mm., and recrystn. of the yellow sublimate from alc. and petr. ether gave cryst. 4-hydroxycoumarone-5-carboxylic acid (II), $C_9H_6O_4$, m. 214°, identical with a sample obtained by Manjunath (*C. A.* 33, 5591[7]) from karanjin from *Pongamia glabra*. Further evidence for the presence of the furan nucleus in I was obtained by oxidizing 0.5 g. of derridenone in 50 cc. of 5% KOH by addn. of 25 cc. of 8% H_2O_2. The mixt. was heated for 1 hr., acidified, extd. with ether and the residue was sublimed at 180–200° in high vacuum, yielding yellow crystals of furan-2,3-dicarboxylic acid, m. 224–5° (decompn.). Oxidation of 2 g. of dehydroderride in 120 cc. of acetone at 0° with 7.2 g. of powd. $KMnO_4$ and vacuum distn. of the crude brown product gave sublimates at 110–20°, 140° and 190–200°. Recrystn. of the 140° fraction from MeOH and redistn. in a high vacuum gave 2,4,5-HO(MeO)$_2C_6H_2CO_2H$ (*C. A.* 26, 2727), m. 209.0–11.5°. Extn. of the fraction 190–200° with MeOH and redistn. *in vacuo* gave rissic acid, $C_{11}H_{12}O_7$, m. 256°. The above results, together with previously published findings, confirm the formula formerly assigned to I.
C. R. Addinall

Alkaline hydrolysis of condensation products of hydantoin with aldehydes. Henry R. Henze, Wm. B. Whitney and Margaret A. Eppright. *J. Am. Chem. Soc.* 62,

565–8(1940).—Wheeler and Hoffman (*C. A.* **5**, 2072) stated that anisalhydantoin (I) with alkali gives *p*-MeO-$C_6H_4CH_2COCO_2H$ (II) but gave no details. Heating 1 g. of I with 100 cc. 5% NaOH at 80–90° for 5 hrs. gives NH_3, $(CO_2Na)_2$ and some *p*-$MeOC_6H_4Me$ (III) and II. Digesting 35 g. I, 300 g. cryst. $Ba(OH)_2$ and 400 cc. H_2O at 120–35° for 100 hrs., during which 150 cc. distillate was collected, gives 7.5 cc. of (mainly) III, some Ba oxalate, 1 cc. anisyl alc., 9 g. of anisic acid and a trace of anisaldehyde. 2-Phenyl-4-(*p*-methoxyphenyl)oxazolone (anisal azlactone) (50 g.) and 750 cc. of 40% NaOH, heated at 110–15°, give some III and 13 g. II. Reaction of $Ba(OH)_2$ upon II in H_2O at 115–20° (15 hrs.) gives III and oxalate. Furfurylhydantoin (30 g.), 320 g. $Ba(OH)_2$ and 350 cc. H_2O, digested 60 hrs. at 110–20°, give oxalate and 8 cc. of 2-methylfuran, b. 63.2°, d_4^{20} 0.9032, n_D^{20} 1.4310. *o*-ClC_6H_4CHO yields 66% of *o-chlorobenzalhydantoin* (IV), m. 275°; $Ba(OH)_2$ gives *o*-ClC_6H_4CHO. Refluxing 10 g. IV, 45 cc. HI (d. 1.7) and 10 cc. AcOH for 2 hrs. gives 7.5 g. of *o-chlorobenzylhydantoin*, m. 240°; hydrolysis with $Ba(OH)_2$ (refluxing 50 hrs.) gives 88% of *o-chlorophenylalanine*, m. 260–1° (*HCl salt*, m. 255–6°). *m-Nitrobenzalhydantoin* (V), bright yellow, m. 277° (58% yield); soly. in boiling AcOH, 1.75–2 g. per 100 cc.; $Ba(OH)_2$ gives *m*-$O_2NC_6H_4Me$ and oxalate. Reduction of V with concd. HCl and Sn (HCl being passed through the soln. at 120° for 6 hrs.) gives *5-(m-aminobenzyl)hydantoin*, whose *HCl salt* m. 270°; $Ba(OH)_2$ gives *m-aminophenylalanine-HCl*, m. 225°. All m. ps. and b. ps. are cor. The above results are to be predicted on the basis of a mechanism previously advanced by H. and Blair (*C. A.* **29**, 148[8]) for the cleavage of the condensation products of hydantoin with isatin and 5-methylisatin. C. J. West

Heterocyclic local anesthetics. Carbazole, dibenzofuran and dibenzothiophene derivatives. Robert R. Burtner and Gerhard Lehmann. *J. Am. Chem. Soc.* **62**, 527–32(1940).—In the study of local anesthetics the effect of the nuclear NH_2 group has been studied, whereas the introduction of an aryl group has received little or no attention; a series of dialkylaminoalkyl esters of the isomeric carbazolecarboxylic acids have been prepd. and to study the effect of replacement of the heterocyclic element by O and S a series of esters of dibenzofuran and dibenzothiophenecarboxylic acids were investigated. Carbazole-2-carboxylic acid (I) (21 g.), 47 g. Bu_2SO_4, 42 g. NaOH in 28 cc. H_2O and 146 g. Me_2CO, shaken for 10 min., poured into 1 l. H_2O contg. 50 g. NaOH, concd. to 500 cc., acidified and the dried ppt. crystd. from petr. ether, give 15 g. of *5-butylcarbazole-2-carboxylic acid* (II), m. 157°. Carbazole-3-carboxylic acid (III) could not be alkylated directly with an iodide or sulfate. 3-Acetylcarbazole (15 g.) and 15 cc. Et_2SO_4 with NaOH in Me_2CO give 15 g. of *5-ethyl-3-acetylcarbazole* (IV), m. 97°; KOH fusion yields 40% of *5-ethylcarbazole-3-carboxylic acid* (V), m. 248°; the *5-Bu analog* of IV m. 74.5–5.°; the *5-Bu analog* (VI) of V m. 198°. III (5.5 g.) in 80 cc. AcOH at 90°, treated with 2 g. $NaNO_2$ and then dropwise with 4.5 cc. concd. HNO_3 in 5 cc. AcOH at 80–5°, gives 6 g. of the *8-NO_2 deriv.* (VII), yellow, m. 338°. *p*-Hydrazinobenzoic acid (38 g.) and 38 cc. cyclohexanone, heated on a steam bath for 15 min. and then refluxed with 400 cc. 10% H_2SO_4 (by vol.) for 15 min., give 40 g. *6,7,8,9-tetrahydrocarbazole-2-carboxylic acid* (VIII), m. 279°. The dialkylaminoalkyl esters were prepd. by conversion to their resp. acid chlorides (by means of PCl_3), followed by treatment with the desired alc., or by way of the ω-chloroalkyl ester which was then treated with the appropriate amine. Passing a slow stream of HCl into a refluxing soln. of 10 g. I in 50 cc. $HOCH_2CH_2Cl$ for 6 hrs. gives 8 g. of the *β-chloroethyl ester*, m. 141°; $HO(CH_2)_3Cl$ gives 18 g. of the *γ-chloropropyl ester* (IX), m. 129°. The acid chloride from 10 g. 5-ethylcarbazole-2-carboxylic acid (X) (heating with PCl_3 on the steam bath for 1.5 hrs.) and 50 cc. $Et_2NCH_2CH_2OH$, heated 10 min. on the steam bath, allowed to stand overnight at room temp., dild. with 500 cc. H_2O contg. 50 cc. 10% NaOH, extn. of the base with ether, and treatment of the crude, distd. base in ether with HCl, give 7 g. of *β-diethylaminoethyl 5-ethylcarbazole-2-carboxylate-HCl*, m. 204°. Heating 17 g. of IX and 11 g. Et_2NH at 110° for 36 hrs. gives 8 g. of *γ-diethylaminopropyl carbazole-2-carboxylate-HCl*, m. 169°. VII yields the *HCl salt* of the *β-diethylaminoethyl ester*, m. 225–7°; reduction with Fe and AcOH gives *β-diethylaminoethyl 8-aminocarbazole-3-carboxylate*, yellow, m. 146–7°. *β-Diethylaminoethyl ester-HCl* of X, m. 195°; of III (free base), m. 127°; of *carbazole-4-carboxylic acid*, viscous oil; of V, m. 174°; of VI, a viscous oil; of VIII, m. 234°; of II (sulfate), a glass. *p*-$PhOC_6H_4CHO$ (35 g.), Ac_2O and AcONa, refluxed 8 hrs., give 10 g. of *p-phenoxyacrylic acid*, m. 135°. Dibenzofuran-2-carboxylic acid (XI) chloride (23 g.) and $HO(CH_2)_3Cl$, heated 5 hrs. at 150°, give 20 g. of the *γ-chloropropyl ester*, m. 85°. The 7-NO_2 deriv. of XI with $SOCl_2$ yields the chloride, m. 225°; $Et_2NCH_2CH_2OH$ gives 85% of the *β-diethylaminoethyl ester* of the 7-NO_2 deriv., m. 161°; reduction with Fe and AcOH gives *β-diethylaminoethyl 7-aminodibenzofuran-2-carboxylate-HCl*, m. 255°. XI yields a *β-diethylaminoethyl ester-HCl*, m. 185°; the *ester* of the *3-isomer* m. 221° and that of the *4-isomer* m. 210°. The *γ-diethylaminopropyl ester-HCl* of XI m. 185°; the *β-isobutylaminoethyl ester-HCl* of XI, m. 212°; the *β-amylaminoethyl ester-HCl* m. 160°. *β-Diethylaminoethyl dibenzofuran-2-acrylate-HCl*, m. 185°. *β-Diethylaminoethyl dibenzothiophene-2-carboxylate-HCl*, m. 219°; *4-isomer*, m. 213°. *β-Diethylaminoethyl p-phenoxybenzoate-HCl*, m. 136°. *β-Diethylaminoethyl p-phenoxyphenylacrylate-HCl*, m. 129–30°. *β-Diethylaminoethyl p-thiophenylbenzoate-HCl*, m. 137°. *β-Diethylaminoethyl dibenzofuran-2,8-dicarboxylate-2HCl*, m. 251–3°. Data are given for the min. duration of visual anesthesia in rabbits for 0.1, 0.5 and 1% solns. and for the av. subcutaneous toxicity in mice. The best compd. of the series is β-diethylaminoethyl 5-ethylcarbazole-3-carboxylate-HCl, which is more than 3 times as potent as cocaine and only 20% as toxic. The activity of these compds. appears to be predominantly a function of the position of the CO_2H group rather than other structural variations. Opening of the C–C bridge in the dibenzofuran and dibenzothiophene derivs. does not improve the therapeutic efficiency. All of the compds. were more or less irritating to the rabbit's eye and to human skin, so that they cannot be regarded as useful anesthetics. C. J. West

Action of carboxylic acid substitution products on methylenepyrazolones. G. Perroncito. *Atti X° congr. intern. chim.* **3**, 267–76(1939); cf. *C. A.* **31**, 6653[8].—After a study of mobile CH_2 in pyrazolones with respect to CO_2Et, the action of carboxylic acid substitution products including $CH_2(CO_2Et)_2$ (I), $(CH_2CO_2Et)_2$ (II), $HCONH_2$ (III), $COCl_2$ and $(COCl)_2$ on 1-phenyl-3-methyl-5-pyrazolone (IV) was investigated. A mixt. of 174 g. IV and 90 g. I was heated at 190° for 3 hrs. and the cooled reddish mass was extd. with petr. ether and washed with toluene. The residue was recrystd. from AcOH, yielding pink silky platelets of *ethoxymethylmethanebis-4-(1-phenyl-3-methyl-5-pyrazolone)*, $C_{24}H_{24}N_4O_3$, m. 281°. Condensation of IV with II similarly gave *γ,γ-bis(1-phenyl-3-methyl-5-pyrazolonyl)-γ-butyrolactone*, $C_{34}H_{24}N_4O_4$, m. 184°. A mixt. of 5 g. IV and 6 g. III was heated for 60–70 min. at 150–60° until yellow crystals formed. Crystn. of the product from AcOH gave good yields of *4,4'-methenylbis(1-phenyl-3-methyl-5-pyrazolone)* (V), $C_{21}H_{18}N_4O_2$. Continuation of the heating at 200° for 20 min. longer caused

(VI)

an evolution of H_2O and NH_3 and converted the yellow crystals into the compd. of III with *3,11-diphenyl-5,9-dimethylpyridinediazole* (VI) (dimethyldiphenyldipyrazolopyridine), $C_{21}H_{17}N_5$.$HCONH_2$, m. 155°. Similar condensation of III with 1,3-diphenyl-5-pyrazolone (VII) gave the

known methenyl analog (VIII) and the corresponding *tetraphenylpyridinediazole* (tetraphenyldipyrazolopyridine), $C_{31}H_{21}N_5$.$HCONH_2$, m. 175°. With $(CONH_2)_2$ at 190° for 1 hr. the pyrazolones IV and VII gave V, m. 180°, and VIII, m. 246°. The reactions of the CH_2 group in IV with substituted CO_2H groups are not general but are controlled by the particular compd. in question.

C. R. Addinall

New research in the group of the isoxazoles. VIII. Sulfonic acid derivatives. Adolfo Quilico and Romeo Justoni. *Gazz. chim. ital.* **70**, 1–11(1940); cf. *C. A.* **34**, 1316⁵.—The β-sulfonic acids and sulfonyl chlorides of α- and γ-methylisoxazole and of α,γ-dimethylisoxazole were obtained by direct sulfonation of the acids with $ClSO_3H$. To 350 g. $ClSO_3H$ add with shaking 83 g. α-methylisoxazole, then reflux on a steam bath for 24 hrs., cool, pour onto ice, filter, dissolve the solid in CCl_4 (soln. *A*) and cool the aq. soln. with ice (soln. *B*). After drying *A* with $CaCl_2$, evap. the CCl_4, and distil *in vacuo*, the α-methylisoxazole-β-sulfonyl chloride, $C_4H_4O_3NSCl$ (I), b_{14-15} 98–9°. On cooling in ice, the colorless oil with strong characteristic odor yields large radiating crystals, m. 23°. I is also obtained in 50% yield by the action of 50 g. PCl_5 on 40 g. of the *sulfonic acid* (II) (see below), heating, and distg. *in vacuo*. I is stable to H_2O, reacts easily with NH_3 and aniline; *sulfonanilide* (III), white shining scales, m. 64°, very sol. in alc., slightly sol. in H_2O. Soln. *B* is treated with 1400 g. $PbCO_3$, filtered, washed with 700 cc. H_2O, the filtrate concd. on a steam bath, H_2S is passed in, the filtrate evapd. and the residual oil extd. with ether, the ether evapd. and the II obtained as a yellow oil is dried and crystd. over H_2SO_4. II is a strong acid, decompg. on heating, and yields *Na, Ca, Ba and Pb salts*, easily sol. in H_2O, sol. in hot alc., slightly sol. in cold alc. and decompg. on heating. *γ-Methylisoxazole* (46 g.) was refluxed with 260 g. $ClSO_3H$ for 46 hrs. and gave 12 g. *sulfonyl chloride* (IV) and 114 g. of the Pb salt of *γ-methylisoxazole-β-sulfonic acid* (V). V is a strong acid, hydrolyzed on boiling in H_2O, yielding low-melting, very hygroscopic crystals. The *Na salt* is obtained from concd. aq. soln. as white needles of the *dihydrate*, yielding the *anhyd. salt* at 100°, and decompg. on stronger heating (evolution of SO_2). The *Ca, Ba and Pb salts* are *anhyd.* when dried at 135°. IV is a colorless oil, b_{21-22} 113–14°; the yield obtained by the action of PCl_5 on V is 60%; it is more stable than the α-isomer (I). *Anilide*, white scales from hot H_2O, m. 62.5°. **IX. Properties of the isoxazolesulfonic acids.** *Ibid.* 11–18. —*α,γ-Dimethylisoxazole-β-sulfonic acid* (VI) was obtained on refluxing 22 g. of α,γ-dimethylisoxazole with 80 g. $ClSO_3H$ for 24 hrs.; yield of *Pb salt*, 35 g. = 87%. VI, m. 50°, is a strong acid in aq. soln., is less hygroscopic than II and V (part VIII, above), and hydrolyzes only on long boiling with H_2O or alkali. The *Na salt* is obtained as a *monohydrate* on evapn. from a satd. soln. at room temp. The *sulfonyl chloride* (VII) is fairly stable even to *hot* H_2O; it forms colorless tablets, m. 34.8°, b_{14} 102–3°, and reacts normally with NH_3 and aniline; the *sulfonamide*, cryst. powder from alc., sol. in hot H_2O, m. 166–7°, and *sulfonanilide*, cryst. powder from 50% alc., m. 122°, are stable to acids and alkalies. When α- or γ-methylisoxazolesulfonic acid or their sulfonanilides are treated with 30% alkali, the N—O bond is broken, NH_3 is liberated, and the mols. decompose. When 5 g. of the Na salt of II (part VIII, above) is treated with 25 cc. of 30% NaOH, a vigorous reaction takes place, and white crystals of *α-sulfoacetoacetic ester* (VIII), sol. in H_2O, stable to air, sep. On boiling with 20% HCl, VIII yields acetone, CO_2 and H_2SO_4. III similarly yields *α-cyanoacetone-α-sulfonanilide*; on boiling with aniline, the *anil* of an acyclic isomerization product, $NCCH(SO_2NHPh)CMe{:}NPh$, white crystals from alc., m. 159–60°, is formed. Similarly the γ-isomer (V, above) of II yields sulfoacetic acid, identified as the Ba salt, and MeCN; finally NH_3 and AcOH.

F. H. Rathmann

Aspartylhistidine. Jesse P. Greenstein and Friedrich W. Klemperer. *J. Biol. Chem.* **128**, 245–50(1939).—*N*-Carbobenzyloxy-*l*-aspartic anhydride with *d*-histidine Me ester in $CHCl_3$ yields the *Me ester*, m. 95–105° (decompn.), of *carbobenzyloxy-l-aspartyl-d-histidine*, m. 171° (decompn.), reduced (Pd in AcOH) to *α-aspartylhistidine*, m. 210°, $[\alpha]_D^{25}$ −6.0° in H_2O. The apparent dissocn. consts. of this and of the β-isomeride (*C. A.* **32**, 7974⁵) have been measured by electrometric titration, and are discussed.

B. C. P. A.

Preparation of substituted xanthones. A. Lespagnol, J. Bertrand and J. Dupas. *Bull. soc. chim.* **6**, 1625–9 (1939).—The method of Dhar (*C. A.* **15**, 231) for obtaining xanthones by treating *o*-hydroxybenzoic acids with phenols in the presence of Ac_2O is not absolutely general. Distn. of the reaction product from the treatment of *o*-$HOC_6H_4CO_2H$ with thymol (I) gave a xanthone (II), m. 169–70°, which was reduced to the xanthydrol with Na-Hg and condensed with urea, yielding dixanthylurea. Thus it appears that reaction had taken place between *o*-$HOC_6H_4CO_2H$ and the phenol resulting from its decarboxylation with the production of II and not the 1-methyl-4-isopropylxanthone (III) expected. A mixt. of 25 g. I and 1.50 g. Na was heated at 100° and the excess Na was destroyed by addn. of MeOH. The product was heated with 5 g. of *o*-$ClC_6H_4CO_2H$ on an oil bath at 150° and treated with 0.10 g. of Cu powder. After the vigorous reaction subsided the heating was continued at 200° for 20 min. The reaction mass was taken up in H_2O, extd. free from I by ether, and pptd. with dil. HCl. The ppt. was taken up in Na_2CO_3, re-extd. with ether and repptd. with HCl. Recrystn. from 50% alc. gave thymylsalicylic acid (IV), $C_{17}H_{18}O_3$, m. 98°. Cyclization of 3 g. IV by heating with 40 g. concd. H_2SO_4 for 1 hr. on the steam bath and working up the product gave III, m. 85°, reduced by Na-Hg to the xanthydrol (V), m. 85°. A mixt. of 0.01 g. urea, 5 cc. AcOH and 0.15 g. V in 2 cc. MeOH gave dimethyldiisopropyldixanthylurea, m. 243°. Similarly an attempt to obtain a xanthone from I and *o*-cresotic acid (VI) by condensation with Ac_2O gave 1,8-dimethylxanthone (VII), m. 165°, by decarboxylation of VI, and condensation of the resulting phenol with the unchanged acid. VII was reduced to a xanthydrol, m. 132°, which was condensed with urea to give tetramethyldixanthylurea.

C. R. Addinall

Structural chemical investigations. I. Nickelous-ion-specific groups. H. Erlenmeyer and H. Ueberwasser. *Helv. Chim. Acta* **23**, 197–206(1940).—Although 4-covalent Ni compds. similar to those with HON:CMe-CMe:NOH are not formed by 1,2-benzoquinone dioxime, 1,2-naphthoquinone dioxime or 1,2-cyclohexanone dioxime, such compds. are given by 2-pyridyl Me ketoxime and the lower-melting form of 2-pyridyl Ph ketoxime. It seemed, therefore, of interest to study the effect of the substitution of the similar isosteric thiazole for pyridine and to prep. the corresponding 4-thiazolyl Me ketoxime (I). A mixt. of 1.8 g. of $BrCH_2COC(:NOH)Me$ (II) (*C. A.* **4**, 2817) in 2.5 cc. acetone and 0.76 g. of thiourea in 15 cc. acetone was warmed, cooled and filtered, yielding 2.3 g. of H_2O-sol. HBr salt, neutralized to give 2-amino-4-thiazolyl Me ketoxime, $C_6H_7N_3OS$, m. 194°. Similar condensation of 1.8 g. II with 2 g. of crude $HCSNH_2$ in 30 cc. ether gave 2 g. of HBr salt (III), neutralized to give the free oxime, crystg. from alc. or benzene in colorless prisms of *4-thiazolyl Me ketoxime* (III), $C_6H_8N_2OS$, m. 153–4°. III (5 g.) in 40 cc. AcOH was heated with 10 g. $NaHSO_3$ for 30 min., and with a further addn. of 5 g. $NaHSO_3$ in 20 cc. AcOH for 1 hr. The hot soln. was treated portionwise with 40 cc. concd. HCl and boiled for 30 min. The soln. was cooled to 50°, filtered and concd., layered with benzene, made alk. with 30% NaOH and extd. with benzene, yielding 2.1 g. of crude ketone, purified by crystn. from petr. ether and sublimation, giving colorless needles of *4-acetylthiazole* (V), C_5H_5NOS, m. 56°. Oxim ation of V with $HONH_2$ in dil. HCl, dil. AcOH or in dil. K_2CO_3 gave only IV and not the 2 syn and anti forms of the oxime. A mixt. of 3 g. AcBr (*C. A.* **1**, 429) in 25 cc. CS_2 and 1.6 g. Br in 10 cc. CS_2 was refluxed in the sunlight, evapd. down, taken up in ether and condensed with 2 g. of crude thiourea in 30 cc. ether

at 30° for 20 min. The crude HBr salt was taken up in 4 *N* HCl, filtered, alkalinated with Na_2CO_3 and shaken out with benzene. The crude extn. product was recrystd. from petr. ether in the presence of charcoal, yielding colorless prisms of *4-benzoylthiazole* (VI), $C_{10}H_7NOS$, m. 49.5°. Oximation of 0.9 g. VI in 50% alc. with 1.5 g. $HONH_2$.HCl and excess AcONa gave yellow prisms, m. about 165°, and colorless needles (VII), m. 104–5°. Recrystn. of the prisms from benzene gave colorless prisms of *4-thiazolyl Ph ketoxime* (VIIa), $C_{10}H_8N_2OS$, m. 174–5°. VIIa was also prepd. by direct synthesis from 1.2 g. of 1-bromo-3-phenylacetone, m. 143° (prepd. by the bromination of 3.3 g. of PhC(:NOH)COMe (*C. A.* **1**, 429) in MeOH satd. with NaBr with 3.2 g. Br), in a little acetone and 1 g. of crude thiourea in 15 cc. ether at 30° for 5 hrs. The crude HBr salt (1.1 g.) was decompd. and recrystd. from benzene, yielding VIIa, m. 174–5°. Alc. solns. of IV, VII and VIIa were treated with $NiSO_4$ soln. and NH_4OH was carefully added to the mixts. but in none of the expts. was there any sign of complex salt formation. The reaction tendency of the nickelous-ion-sp. groups depends on the mesomeric structure of the groups. The relation between structure and sp. activity must not only be sought in the criteria expressed by the classical formula but in the characteristic differences made evident by the findings of modern structural chemistry. The mesomer of IV, which should give a secondary valence ring with nickelous ion, is not constituted like the corresponding mesomer of pyridine. It is conceivable that the 3,4-N—C linkage of thiazole and the corresponding 1,2-N—C linkage of pyridine, are both aromatic in nature but not equiv. C. R. Addinall

β-Arylaminoacrylic esters. II. Synthesis of *N*-aryl-4-pyridone-3-carboxylic acids. M. V. Rubtsov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1517–24(1939); cf. *C. A.* **32**, 526[1]. —By following previous procedures, β-arylaminoacrylic esters are prepd. by condensation of $HOCH:CHCO_2Et$ with arylamines in dil. AcOH; the esters on heating *in vacuo* 10–15° below the m. ps. form β-aryliminodiacrylic esters (I); these when sapond. with alc. KOH cyclize to the corresponding *N*-aryl-4-pyridone-3-carboxylic acids. In the prepn. of *N-(2-naphthyl)-4-pyridone-3-carboxylic acid* (II) and *N-phenyl-4-pyridone-3-carboxylic acid* (III) the intermediate I could not be isolated. *β-2-Naphthylaminoacrylic ester*, leaflets, m. 134–5°. II exists in 2 isomeric forms, m. 306–7° and 252–3°, which were sepd. as the K salts. *β-Anilinoacrylic ester*, m. 105–6°. III, needles, m. 263–4°. *β-6-Quinolylaminoacrylic ester* (from 6-aminoquinoline), prisms, m. 155–6°. The *diacrylic ester*, needles, m. 127–8°. *N-(6-Quinolyl)-4-pyridone-3-carboxylic acid*, powder, m. 353–5° (decompn.); *chloride*, m. 262–3°; *Et ester*, m. 116–17°; *diethylamide*, m. 155–6°. Most of these compds. are pale yellow of different shades. Chas. Blanc

Pyridine and piperazine derivatives of sulfanilamide. Wm. O. Kermack and Walter Tebrich. *J. Chem. Soc.* 1940, 202–5.—*o*-Aminopyridine (0.5 g.) and 1.4 g. of $3,4\text{-}O_2N(AcNH)C_6H_3SO_2Cl$ in C_5H_5N give 1.2 g. of *2-(3'-nitro-4'-acetamidobenzenesulfonamido)pyridine* (I), yellow, m. 270°. Heating 5 g. I with 25 cc. 5 *N* HCl on the water bath for 0.5 hr. gives 4 g. of the free *amine* (II), yellow, m. 232°; refluxing 4 g. II with 40 cc. 25% NaOH and acidifying with 10% HCl give 3.8 g. of *2-(3'-nitro-4'-hydroxybenzenesulfonamido)pyridine*, pale yellow, m. 234°; reduction of 1 g. in 12 cc. *N* NaOH with 2 g. of $Na_2S_2O_4$ gives 0.4 g. of the *3'-NH_2 deriv.*, m. 211°; it is readily oxidized in the air, especially in aq. soln. Shaking 2.36 g. of *p*-$AcNHC_6H_4SO_2Cl$ (III) in wet ether with 1 g. piperazine (with 6 H_2O) in 0.1 *N* NaOH gives 1.75 g. of the *di-Ac deriv.*, m. 324°, of *1,4-di(p-aminobenzenesulfonyl)piperazine*, m. 331–2°. Since the monosubstituted deriv. could not be prepd. in this manner, 9.6 g. Et piperazine-1-carboxylate and 13.8 g. of III were condensed with 0.1 *N* NaOH in MeOH-Et_2O, giving 18.5 g. of the *Ac deriv.*, m. 132°, of *Et 4-(p-aminobenzenesulfonyl)piperazine* (IV), m. 170° (HCl salt, m. 198°); refluxing 2 g. of IV with 10% EtOH-NaOH for 4 hrs. gives 0.8 g. of *1-p-aminobenzenesulfonylpiperazine*, m. 204°. IV (1.6 g.) and 1.2 g. III in C_5H_5N give 1.2 g. of *Et 4-(p-acetamidobenzenesulfonamidobenzenesulfonyl)-piperazine-1-carboxylate*, m. 194°; this could not be hydrolyzed. C. J. West

Separation of β-picoline, γ-picoline and 2,6-lutidine from their mixture. Alan G. Lidstone. *J. Chem. Soc.* 1940, 241–3.—A "β-picoline fraction" (I), b. 142–4° (100 cc.), is warmed to 80°, 110 g. com. anhyd. $(CO_2H)_2$ added during 10 min. and 150 cc. boiling abs. EtOH stirred in; after cooling and sepn. of the cryst. mass the filtrate and wash EtOH are reserved for the prepn. of 2,6-lutidine (II). Crystn. of the pptd. oxalates from abs. EtOH (twice without filtration and a 3rd time with hot filtration) gives γ-picoline (III) oxalate, m. 137–8°; the mother liquor gives the β-isomer (IV), m. 112–21°. The use of hydrated $(CO_2H)_2$, treatment of batches larger than 100 cc. at a time and heating solns. for more than the min. time necessary seriously diminish the yield. III and IV are obtained from the oxalates by soln. in the min. quantity of H_2O and distn. with an excess of 50% KOH. The initial filtrate and washings give a const. boiling mixt. of II and H_2O, 200 cc. of which is dild. with 100 cc. concd. HCl and 150 cc. H_2O and treated with 200 g. of $HgCl_2$ in 1 l. boiling H_2O; the $HgCl_2$ salt m. 187–8°; steam distn. with 30% NaOH gives II. I (700 cc.) yields 158 g. III, 71 g. IV and 267 g. II; 100 g. recovered base is mostly IV and is again treated as above. The rather less satisfactory sepn. of the IV oxalate is probably due to some esterification of the $(CO_2H)_2$, as the mother liquor on repeated evapn. becomes sirupy. C. J. West

Some α-picolines substituted in the β-position. Alfred Dornow. *Ber.* **73B**, 78–80(1940).—As was recently reported, 2,3-derivs. of pyridine are readily obtained by the action of $EtOCH:CHCH(OEt)_2$ on ketimine-enamine compds. of the general type $RC(:NH)CH_2R' \rightleftarrows RC(NH_2):CHR'$ (*C. A.* **33**, 8200[9]). The 2-methylnicotinic ester (I) obtained in this way is peculiarly well suited for the prepn., by transformations of the carboxyl group, of α-picolines substituted in the adjacent β-position. Because of the great physiol. importance of nicotinamide, *2-methylnicotinamide* (II) was prepd. from I with NH_3 but it gave a neg. anti-rat pellagra test. A no. of other derivs. of α-picoline prepd. from II are described. II (4.2 g. from 10 g. I shaken in 100 cc. of 25% NH_4OH until completely dissolved (about 2 days)), m. 158°; *picrate*, m. 180–1° (decompn.). *2-Methyl-3-aminopyridine* (III) (2.5 g. from 4.2 g. II in 80 cc. of 10% KOH heated 0.5 hr. on the water bath with 30 cc. NaOCl soln. (Raschig, *C. A.* **2**, 636)) sublimes about 60° *in vacuo*, m. 115–16°; *picrate*, m. 234° (decompn.). *3-Benzoylamino compd.* (0.8 g. from 0.5 g. III by the Schotten-Baumann method), m. 114–15°. *3-I compd.*, from III diazotized in cold HCl and treated with KI, m. 36–7°, is easily volatile and has a characteristic odor; *picrate*, m. 168° (decompn.). *3-HO compd.* (IV) (0.35 g. from 0.5 g. III diazotized in H_2SO_4 with the calcd. amt. of $NaNO_2$ and heated on the water bath until the evolution of N ceased), m. 167–8°, gives a deep red color with $FeCl_3$; *picrate*, m. 204° (decompn.). IV showed no adermine-like physiol. action. C. A. R.

Action of methyl isothiocyanate on ethyl acetonedicarboxylate. David E. Worrall. *J. Am. Chem. Soc.* **62**, 675(1940); cf. *C. A.* **34**, 766[2].—The di-Na deriv. from 0.1 g.-mol. of $CO(CH_2CO_2Et)_2$ and 2 equivs. of MeNCS, heated 1 hr. and decompd. in the usual way, give 4.5 g. *1-methyl-2,4-dioxo-5-carbethoxy-6-thiopiperidine-3-thioformmethylamide* (I), bright yellow, m. 98°; the original material contains 0.3 g. of an insol. portion, pale yellow, m. 235–6°; the formula may be $C_{13}H_{14}N_4O_5S_4$. I and MeI-EtOH, boiled 30 min., give the *6-methylmercapto compd.* (II), m. 110°. Bromination of II in AcOH gives *dispiro-3,3'-di(1-methyl-2,4-dioxo-5-carbethoxy-6-thiopiperidine)-3'',3'''-(1,4-dimethyl-2,5-dithiopiperazine)*, cream, m. 180°. C. J. West

Aryl isothiocyanates and ethyl acetonedicarboxylate. David E. Worrall. *J. Am. Chem. Soc.* **62**, 578(1940); cf. *C. A.* **34**, 766[2].—Addn. of 0.05 g.-mole of $CO(CH_2CO_2Et)_2$ to 0.1 g.-mole of pulverized Na in ether and then

0.05 g.-mole of the isothiocyanate, decompn. after several hrs. with cold dil. HCl and crystn. from EtOH or EtOH-C_6H_6 give 3–8 g. of the following derivs. of *2,4-dioxo-5-carbethoxy-6-thiopiperidine-3-thioformic acid;* MeI in EtOH gives the 6-MeS compds., bright yellow. *1-Ph anilide,* CO.NPh.CS.CH(CO_2Et).CO.CHCSNHPh, m. 188–9° (all these derivs., m. with decompn.) (*6-MeS compd.,* m. 148–9°); *1-m-tolyl m-toluide,* m. 125–6° (*MeS compd.,* m. 137–8°); *1-p-anisyl aniside,* m. 162–3° (*Me compd.,* m. 152–3°); (*1-p-phenetyl phenetide,* m. 195–7° (*MeS compd.,* m. 114–15°); *1-p-bromophenyl p-bromoanilide,* m. 179–81° (*MeS compd.,* m. 152°). The (*2',4'-dioxo-5'-carbethoxy-6'-thiopiperidyl*)*benzothiazoles* ppt. from glacial AcOH by the action of Br; the m. ps. were too high to be recorded with a H_2SO_4 bath: *1'-Ph, 1'-m-tolyl-4*(or 6)*-methyl, 1'-p-anisyl-5-methoxy, 1'-p-phenetyl-5-ethoxy* and *1'-p-bromophenyl-5-bromo.* C. J. West

ms-**Derivatives of acridine. XIV. Alkylation of 9-chloroacridines.** N. S. Drozdov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1456–7(1939); cf. Cherntsov and Drozdov, *C. A.* **34**, 1667[6,7].—Alkyl esters of *p*-$MeC_6H_4SO_3H$ and derivs. of 9-chloroacridine when heated 1 hr. at 130° give good yields of alkylacridones (cf. *C. A.* **32**, 568[8]). The reaction probably proceeds by decompn. of unstable intermediate 9-chloro-10-alkylacridinium *p*-toluenesulfonates. In this way were prepd. 10-methyl-, m. 198–9°, 2,10-dimethyl-, m. 150–1°, and 3-chloro-7-methoxy-10-methylacridone, m. 245–6°.

Chas. Blanc

Local anesthetics of the 4-quinolinecarboxylic acid series. I. S. I. Lur'e. *J. Gen. Chem.* (U. S. S. R.) **9**, 287–98(1939).—To study the effect of the ester group and of substituents in the 2-position on the anesthetic properties, a no. of 2-substituted cinchoninic acids (as Na salts) are condensed with $Et_2N(CH_2)_2Cl$ (I), $Et_2N(CH_2)_3Cl$ (II), *Et*$_2$*NCH*$_2$*CMe*$_2$*CH*$_2$*Cl* (III) and *Et*$_2$*NCH*$_2$-(*CHMe*)$_2$*Cl* (IV) in xylene to form the corresponding dialkylaminoalkyl esters. The m. ps. of the 2-EtO (V), 2-PrO (VI), 2-BuO (VII), 2-iso-BuO (VIII) and 2-iso-AmO (IX) derivs. of cinchoninic acid are 144–5°, 136–7°, 98° (111°), 145–6° and 120–2°, resp. The m. ps. of the diethylaminoethyl esters of cinchophen (X), V, VI, VII, VIII and IX, as the HCl salts, are 185–6°, 170.0–0.5°, 169.5–170.5°, 149°, 152–3° and 160–1°, resp. The m. ps. of the *diethylaminopropyl esters* of X and VI, as *HCl salts,* are 178–9° and 136°, resp. II with V gives a hygroscopic *HCl salt; amine,* as *citric acid salt,* m. 99–100°. II with VII gives the *di-HCl salt,* amorphous mass; free *amine,* yellow oil, $b_{2.5}$ 207–11°, whose *citric acid salt,* m. 115–16°. The m. ps. of the *β,β-dimethyl-γ-diethylaminopropyl esters* of V, VI, VII and X, as *HCl salts,* are 115–16° (free *amine,* yellow oil, b_3 207°), 123–4°, 137–8° (free *amine,* b_3 207–10°) and 176–7° (*amine,* cream, m. 44–6°), resp. IV with VII gives the corresponding *ester* (XI), yellow oil, b_3 214–17°; *citric acid salt,* m. 78–9°. *α,α*-Dimethyl-*β*-diethylaminopropionaldehyde, b. 173–9°, reduction with Na-Hg in AcOH gives the *alc.*, b_{14} 90–2°, which with $SOCl_2$ in C_6H_6 gives (69% yield) III, b_{10} 72°. MeCOEt with paraformaldehyde and Et_2NH.HCl in EtOH gives (70% yield) *MeCOCHMeCH*$_2$*NEt*$_2$, b_{15} 78–80°, from which is obtained the secondary *alc.*, $C_9H_{21}NO$, b_{12} 84°. The alc. with $SOCl_2$ gives (80% yield) IV, b_{12} 78–9°. All of the above esters exert a strong anesthetic action when placed on the cornea, the potency depending somewhat on the structure of the 2-alkoxy group but chiefly on the ester group, increasing with the no. of C atoms in the side chain. The most toxic of the esters, whose toxicities lie between those of novocaine and cocaine, is the diethylaminopropyl ester of VII. Nearly all of the esters are irritating to the mucous membranes, those with a 5-C ester group producing the most intense irritation.

John Livak

Isoquinoline series. III. 1-Chloroalkylisoquinolines and their derivatives. B. B. Dey and T. R. Govindachari. *Arch. Pharm.* **277**, 177–92(1939); cf. *C. A.* **32**, 171[8].—The Cl of 1-(*α*-chloroalkyl)-3,4-dihydroisoquinolines can be exchanged for OH or CN, but not for NH_2 or NR_2; it is eliminated by hydrogenation. Piperonal (20 g.) yields successively 3,4-methylenedioxyphenylacrylic (22 g.), m. 247°, and -propionic acid (17 g.), m. 87°, the amide (13 g.), m. 122°, of the latter acid, and homopiperonylamine (I) (6.5 g.), b_{10} 200°. $(CH_3ClCO)_2O$ (modified prepn. from AcOH and PCl_5), b_{25} 128–30°, in $CHCl_3$ then gives *chloroacethomopiperonylamide,* m. 71°, which with hot $POCl_3$ yields *6,7-methylenedioxy-1-chloromethyl-3,4-dihydroisoquinoline* (II), m. 109° (decompn.) (*HCl salt,* m. 190°; *methiodide,* m. 230°; *picrate,* m. 180°). Zn dust in 2 *N* H_2SO_4 eliminates the Cl from II, yielding *6,7-methylenedioxy-1-methyl-1,2,3,4-tetrahydroisoquinoline,* an oil (*picrate,* m. 185°; *HBr salt,* m. 268°), also obtained from I by successive treatment with Ac_2O, $POCl_3$, and Zn-H_2SO_4. Only resins are obtained from II with NH_3 or NH_2Ph, and Mg does not react. With NaOH-EtOH at 50° II gives *6,7-methylenedioxy-1-hydroxymethyl-3,4-dihydroisoquinoline,* m. 215° (acetate and benzoate could not be purified), reconverted into II by $POCl_3$ at 100°. With KCN-EtOH, II gives *6,7-methylenedioxy-1-cyanomethyl-3,4-dihydroisoquinoline* (III), m. 187° [*vanillylidene,* sinters at 230°, m. 250° (*HCl salt,* sinters at 250°, m. 255°), *benzylidene,* sinters at 160°, m. 180° (*HCl salt,* m. 204°), and *piperonylidene derivs.,* m. 268–9° (*HCl salt,* sinters at 259°, m. 265°), hydrolyzed when reduced, even by H_2-Pt], reduced by Zn dust in 4 *N* H_2SO_4 to *6,7-methylenedioxy-1-cyanomethyl-1,2,3,4-tetrahydroisoquinoline,* m. 93° (*picrate,* m. 190°; *HCl salt,* m. 254°; *methiodide,* m. 215°; *Ac,* m. 139°, and *NO derv.*, m. 138°). III reacts with H_2O_2 to yield AcOH and *1-keto-6,7-methylenedioxy-1,2,3,4-tetrahydroisoquinoline,* m. 183° (cf. Perkin, *J. Chem. Soc.* **57**, 992(1890)), reduced by Na-EtOH to 6,7-methylenedioxy-1,2,3,4-tetrahydroisoquinoline, which is also obtained from $CH_2O_2C_6H_3(CH_2)_2NHCHO$ by $POCl_3$, followed by Zn-H_2SO_4. 3,4-$CH_2O_2C_6H_3(CH_2)_2NHCOCH$-MeOH (prepd. from the base by HOCHMeCO_2H at 180°) and $POCl_3$ give *6,7-methylenedioxy-1-α-chloroethyl-3,4-dihydroisoquinoline,* an oil (*picrate,* m. 184°; *methiodide,* m. 275°), reduced by Zn-H_2SO_4 to *6,7-methylenedioxy-1-ethyl-1,2,3,4-tetrahydroisoquinoline,* an oil (*picrate,* m. 207°; *HCl salt,* m. 240°), which is also obtained from I and $(EtCO)_2O$, followed by $POCl_3$ and Zn-H_2SO_4. The 1-*α*-NH_2 deriv. could not be prepd. By methods outlined above are obtained *6,7-methylenedioxy-*, an oil (*picrate,* m. 178°), and *6,7-dimethoxy-1-α-cyanoethyl-3,4-dihydroisoquinoline* (*picrate,* m. 186°), *6,7-dimethoxy-1-α-chloroethyl-3,4-dihydroisoquinoline,* m. 175° (*methiodide,* m. 260°), and *6,7-dimethoxy-1-ethyl-1,2,3,4-tetrahydroisoquinoline,* an oil (*picrate,* m. 186°; *HCl salt,* m. 214°).

B. C. P. A.

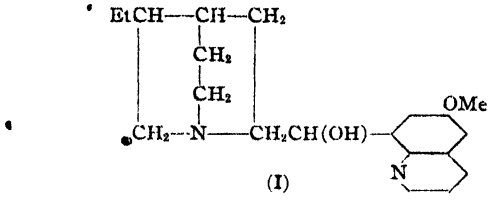
Carbethoxy substitution on the nitrogen atom of barbitals. Harold J. Termey and Glenn W. Humphreys, Jr. *St. Bonaventure Sci. Studies* **8**, No. 2, 9–16(1940).—*N*-Substituted barbitals are suggested as possible new derivs. which have pharmacol. activity. 1-Na 5-ethyl-5-phenylbarbiturate (42 g.) refluxed with 33.4 cc. of $ClCO_2Et$ (with agitation) for 4 hrs. gave a milky uniform mixt. which on diln. with 400 cc. of H_2O, filtration and sepn. gave 40 cc. of an immiscible yellowish brown oil. This oil crystd. on standing into rosettes of needles, m. 69.5–70°. Alc. extn. of the residue (from the above H_2O diln. and filtration) followed by evapn. gave crystals of the same m. p. as the crystals obtained from the oil. Repeated crystn. from alc. gave a m. p. of 73–3.5° (cor.) for the purified product. Analysis of this product gave C 57.77, H 5.13, N 7.55, O 29.55% (by difference), mol. wt. 310.15, neutralization equiv. 384. Except for the mol. wt., these values agree fairly closely with those calcd. for 1,3-dicarbethoxy-5-ethyl-5-phenylbarbituric acid. Min. effective dose (orally to mice) 2000–2200 mg./kg., min. lethal dose 2400 mg./kg. where the tests were made 8 months after prepn. Tests made 14 months after prepn. showed no pharmacol. response. R. F. D.

2-Methyl-3-hydroxyethyl-*N*-(2-methyl-4-amino-5-pyrimidylmethyl)pyridinium bromide, a heterovitamin B_1. Paul Baumgarten and Alfred Dornow. *Ber.* **73B**, 44–6 (1940).—In view of the frequently observed similarity in phys. and chem. and also in physiol. properties of thia-

zoles and the corresponding pyridine compds. it was to be expected that replacement of the thiazole component in vitamin B_1 (I) by a corresponding pyridine complex would give a *heterovitamin* B_1 (II) with similar, though perhaps quantitatively different, physiol. activity. 2-Methylpyridine-3-carboxylic acid-HCl (5 g.), refluxed in 5 parts $SOCl_2$ until dissolved, freed from the excess of $SOCl_2$ by distn. *in vacuo*, and gradually treated in ether suspension at 0–5° with 3.25–3.5 mols. CH_2N_2 in ether, gave 3.2 g. *2-methyl-3-diazoacetylpyridine*, m. 58–9° (*picrate*, m. 147°), which, cautiously heated in AcOH until the evolution of N ceased and refluxed 10–15 hrs. with amalgamated Zn and concd. HCl, yielded *2-methyl-3-hydroxyethylpyridine* (III), b_{12} 142–3°, b_{18} 147.5°, hygroscopic oil smelling like poppyseed oil (*methiodide*, m. 135°; *benzoate picrate*, yellow, m. 190–200° (decompn.)). Allowed to stand overnight at about 40° with 2-methyl-4-amino-5-bromomethylpyrimidine-2HBr in $MeNO_2$, 0.4 g. II gave 0.25 g. *2-methyl-3-hydroxyethyl-N-(2-methyl-4-amino-5-5-pyrimidylmethyl)pyridinium bromide-HBr*, $C_{14}H_{20}ON_4Br_2$ (II), m. 246–7°. II was physiologically active in the pigeon test but only $^1/_{26}$th as much as I. In the meantime the prepn. of II by another method has been reported by Schmelkes and Joiner (*C. A.* **33**, 8615[8]). C. A. R.

Formation of aldimine-amine complexes in the hydrogenation of aminonitriles by catalytic nickel. Marcel Delépine and K. A. Jensen. *Bull. soc. chim.* **6**, 1663–70 (1939); cf. *C. A.* **32**, 8427[7].—Three new examples of the transformation of the CN function into a CH:NH group in the hydrogenation of 2 aminonitriles and a cyanophenol by Raney Ni are reported. The aldimines sep. out in complexes due to participation of Ni in the reaction. A mixt. of 2 g. of 2-ethyl-4-amino-5-cyanopyrimidine (I), m. 207°, 2 g. Raney Ni, 25 cc. alc., 25 cc. of 20% NH_4OH, 2 g. $NiCl_2.6H_2O$ and 200 g. H_2O took up 313 cc. H in 50 min., yielding a yellow ppt. Extn. with boiling dil. AcOH gave 0.15 g. of aldehyde (II) and 0.10 g. of oxime (III). The mother liquors were heated with an excess of NH_4OH on the steam bath and yielded 0.50 g. of an orange complex (IV). The filtrate from the yellow ppt. was concd., acidified with HCl and filtered. The mother liquors from the cryst. NH_4Cl were pptd. with picric acid and gave 1.1 g. of long needles of a diamine dipicrate (V). Repetition of the hydrogenation with 5 g. I and proportional parts of the other ingredients gave a fixation of 1.4 mol. H in 100 min. and yielded 0.75 g. II. A 3rd expt. with 5 g. I but with limited solvents and operation at 3 atm. gave 1.05 g. II, 1.20 g. IV and 3.65 g. V. II, $C_7H_9N_3O$, m. 164° (*2,4-dinitrophenylhydrazone*, m. 290° (decompn.)), when shaken for 24 hrs. with Raney Ni, alc. 20% NH_4OH and H_2O gave IV, $(C_7H_9N_4)_2Ni.4H_2O$, on extn. with boiling 70% alc. and air drying. V, $C_7H_{12}N_4.2C_6H_2(NO_2)_3OH$, m. 240° (decompn.). Catalytic hydrogenation of 2 g. of *o*-$H_2NC_6H_4CN$ with 1.65 mol. H gave the diamine $H_2NC_6H_4CH_2NH_2$ but the complex isolated by Pfeiffer (*C. A.* **32**, 512[7]) was too sol. in $PhNO_2$ to permit its isolation. The reduction was repeated and limited to 1 mol. H. The red ppt. formed was extd. with boiling $PhNO_2$ and gave red crystals of $C_{14}H_{14}N_4Ni$ (VI), corresponding to the product prepd. by Pfeiffer from *o*-$H_2NC_6H_4CHO$ (VII). VII behaves in a more complicated manner on reduction with Raney Ni in the presence of NH_4OH for, in addn. to the formation of VI, $CHCl_3$-sol. compds. are formed consisting of amino-aldehyde condensation products which have formed imines and produced a Ni complex. A mixt. of 5 g. of 2-HOC_6H_4CN, 4 g. Ni, 50 cc. MeOH, 250 cc. H_2O, 6 g. $NiCl_2.6H_2O$ and 25 cc. of 20% NH_4OH was reduced with 1070 cc. H in 140 min. The product was extd. with boiling pyridine and dild. with an equal vol. of MeOH, yielding red crystals identical with the combination prepd. from 2-HOC_6H_4-CHO, NH_4OH and a Ni salt. All the expts. show that Ni is not restricted to a catalytic role in these reductions but also takes part in the chem. reactions by participating in complex formation. C. R. Addinall

Series of 2-methyl-5-alkyl-4,6-dihydroxypyrimidines. Livingston P. Ferris II and Anthony R. Ronzio. *J. Am. Chem. Soc.* **62**, 606–7(1940).—Acetamidine-HCl ($^1/_8$ mol.), added to 150 cc. abs. EtOH and 3.3 g. Na, followed by 0.05 mol. of $CH_2(CO_2Et)_2$ or its monoalkyl deriv., and allowed to stand 2–3 days, the soln. exactly neutralized with concd. HCl, H_2O added to dissolve the NaCl, the undissolved pyrimidine filtered, decolorized in boiling AcOH and repptd. with Et_2O, gives the following 2-methyl-5-alkyl-4,6-dihydroxypyrimidines, the group in position 5 being: *H* (I) (43%), *Me*, (18%), *Et* (15%), *Pr* (22%), *Bu* (II) (33%) and *Am* (26%). These do not show definite m. ps. but sublime between 260–350°; in a sealed tube they decomp. without melting. The absorption spectra curves are given for I in H_2O, HCl and KOH and for II in EtOH. C. J. West

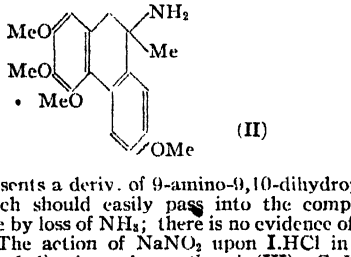


Pyrazine series. II. Preparation and properties of aminopyrazine. Stanley A. Hall and Paul E. Spoerri. *J. Am. Chem. Soc.* **62**, 664–5(1940); cf. *C. A.* **32**, 2535[8].—Pyrazinecarboxylic acid, m. 225° (decompn.), results in 70% yield by heating pyrazine-2,3-dicarboxylic acid at 210° in a vacuum sublimation chamber; Me ester, m. 59°; amide (I), m. 189° (Brit. pat. 451,304, *C. A.* **31**, 2191). Addn. of 6.9 g. of I to 4.2 g. of Cl and 13.8 g. NaOH in 150 cc. ice and H_2O gives, on standing overnight, 3.5 g. of a product (II), the alk. soln. of which evolves CO_2 on acidification; evapn. of the AcOEt ext. gives 1.5 g. aminopyrazine (III), sublimes at 100° and 3 mm., m. 117–18° (Gabriel and Sonn, *C. A.* **2**, 851 give 110–17°); the picrate decomps. 214–50°; *Ac deriv.*, m. 133°; the yield of III as such and as picrate is 55%. II is *Na pyrazinecarbamate*, $C_5H_4N_3O_2Na$, blackens 275°; its formation confirms Mohr's theory of the mechanism of the Hofmann reaction (*J. prakt. Chem.* **73**, 117, 229(1906)) and also shows the characteristic stabilizing effect of the pyrazine ring upon certain functional groups. C. J. West

Coloration phenomena of derivatives of 2-thio-3-aryl-4-hydroxy-1,2,3,4-tetrahydroquinazolines. Lucie Manolescu-Pavelescu. *Bull. sect. sci. acad. roumaine* **20**, No. 6, 28–9(1938)(in French); cf. *C. A.* **33**, 4994[8].—Derivs. of 2-thiotetrahydroquinazoline with *o*-tolyl or *p*-tolyl radicals in position 3 give yellow mercaptanic salts with $AgNO_3$. A short review of some of the data in *C. A.* **33**, 4994[6] is also given. George Ayers

New series of alkyl derivatives of *asym*-tetrahydro-oxothiotriazines. Eugène Cattelain. *Compt. rend.* **210**, 301–3(1940); cf. *C. A.* **34**, 991[3].—2-Alkylthiosemicarbazides combine with phenylpyruvic acid to form 2-alkylthiosemicarbazones (I): $PhCH_2COCO_2H + SC(NH_2)NRNH_2 = PhCH_2C(CO_2H):NNRCSNH_2$ (I) + H_2O, which by further dehydration under the influence of cold dil. alkali readily cyclize to benzyltetrahydroöxothiotriazines, $PhCH_2C{:}N.NR.CS.NH.CO$ (II). The I are very sol. in EtOH, $COMe_2$ and Et_2O, insol. in cold, sol. in hot H_2O and decomp. alkali carbonates. With R = Me, I m. about 250° but sublimes at 230–40° (partial decompn.); I with R = $PhCH_2$, m. 174°. The II are insol. in H_2O, slightly sol. in cold, very sol. in hot EtOH, sol. in dil. alkali, and repptd. by CO_2; II with R = Me, m. 153–5°; R = $PhCH_2$, m. 123°. C. A. Silberrad

Synthesis of isomers of hydroquinine. I. (5-Ethyl-2-quinuclidyl)(6-methoxy-8-quinolyl)methanol. M. V. Rubtsov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1493–1506 (1939).—The physiol. effect of the transfer of the quinuclidyl group from the 4- to the 8-position in the quinine mol. is studied. I was prepd. by a somewhat modified method of Rabe, *et al.* (*C. A.* **26**, 475), for the synthesis of hydroquinine. Et 6-methoxyquinoline-8-carboxylate and benzoylhomocincholoipon Et ester were condensed by the Claisen method to the *keto ester*, m. 54–6°; sapon. with 17% HCl gave *isohydroquinotoxine* (*$PtCl_4$ salt*, m. 282–5° (decompn.)). The toxine reacts with 2 mols. HBr to give the *di-HBr salt*, m. 193–4° (decompn.). The dibromide was cyclized into *isohydroquininone*, m. 152–3°, by the action of 10% Na_2CO_3 and C_6H_6. Reduction of the ketone with Al isopropylate in dry C_6H_6 gave a mixt. of optical isomers of the isohydroquinine (I). To sep. the stereoisomers, these were converted into bitartrates and extd. with $CHCl_3$ and a little H_2O. The distn. residue was decompd. with dil. Na_2CO_3



and recrystd. from ether, giving an isomer of hydroquinine, m. 177.5–8°, $[\alpha]_D^{20}$ 135.9°. The aq. ext. of bitartrates with Na_2CO_3 formed a glass-like mass, m. below 50°, $[\alpha]_D^{20}$ 64.3°. If analyzed for I, but was a mixt. of stereoisomers, since its picrolonate gave a base with lower sp. rotation ($[\alpha]_D^{20}$ 52°). The compds. when tested on finches infected with *Plasmodium praecox*, showed no antimalarial action. The anesthetic action was retained. 30 references.

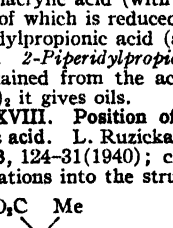
Chas. Blanc

Colchicine and related compounds. I. Some observations on the structure of colchicine. A. Cohen, J. W. Cook and E. M. F. Roe. *J. Chem. Soc.* **1940**, 194–7.—On the basis of Windaus' structure for colchicine (*C. A.* **18**, 3374) the degradation product colchinol Me ether (I) should have the formula

(II)

but this represents a deriv. of 9-amino-9,10-dihydrophenanthrene which should easily pass into the completely aromatic state by loss of NH_3; there is no evidence of such instability. The action of $NaNO_2$ upon I.HCl in 10% AcOH (ice-cooled) gives the *methanol* (III), $C_{19}H_{22}O_5$, b_3 230°, m. 115–16.5° (*p-phenylbenzoate*, m. 146–7°). III could not be oxidized with CrO_3 or $KMnO_4$ with the production of cryst. or acidic products (in 1 case a semicarbazone, m. 149–50°, was isolated). In other expts. there was obtained a *compd.*, m. 133–4°, which appears to be an isomer of III. III does not react in C_6H_6 with $C_6H_4(CO)_2O$ but yields a *H phthalate*, m. 143–4°, on heating the components at 180° for 1 hr. III is not dehydrogenated on heating with $(iso\text{-}Am)_2S_2$ at 210°; it gives a compd. m. 157–60°, which yields a *p-phenylbenzoate*, m. 108–9°. *N*-Acetylcolchinol Me ether (IV) is recovered unchanged after heating with Pt black at 280°. The ultraviolet absorption curves of III and IV in EtOH are given. The curve for IV is very similar to that for 9,10-dihydrophenanthrene; that for III has much the same intensity but the band is considerably displaced toward the visible region; it is evident that III is not a phenanthrene deriv. If I is a dihydrophenanthrene deriv., the tetra-MeO deriv. should be 2,3,4,6- or 2,3,4,7-tetramethoxy-9-methylphenanthrene, whose synthesis is being undertaken. There is the possibility that the action of HNO_2 upon I is attended by mol. rearrangement. II. **Synthesis of a simple analog of *N*-acetylcolchinol methyl ether.** J. W. Cook and Lewis L. Engel. *Ibid.* 198–200.—3,4,5-$(MeO)_3C_6H_2CHO$ (I) (9.8 g.), 9 g. of $PhCH_2CO_2Na$ and 25 cc. Ac_2O, heated at 150–60° for 5 hrs., give 5.5 g. of *α-phenyl-β-(3,4,5-trimethoxyphenyl) acrylic acid*, m. 186–7°; *p-phenylphenacyl ester*, m. 123.5–4.5°; hydrogenation in HOAc with Pd black for 4 hrs. at room temp. give 3.9 g. *α-phenyl-β-(3,4,5-trimethoxyphenyl)propionic acid* (II), $b_{0.5}$ 215–19°; *p-phenylphenacyl ester*, m. 94–5°. Condensation of 6.9 g. of I and 4.1 g. $PhCH_2CN$ by shaking with aq. NaOH in EtOH gives 6.8 g. of *α-cyano-α-phenyl-β-(3,4,5-trimethoxyphenyl)ethylene*, m. 77–9°; reduction by H and Pt oxide, followed by boiling with 25% EtOH-KOH for 11 hrs. gives II. Nitration expts. with II lead to profound decompn. of the acid. I (9.8 g.), 9.4 g. *p*-$MeOC_6H_4CH_2CO_2Na$ and 25 cc. Ac_2O, heated 5 hrs. at 140–60°, give 4.9 g. of *α-p-anisyl-β-(3,4,5-trimethoxyphenyl)acrylic acid* (III), m. 207–8°; *Et ester*, m. 84–5°; *p-phenylphenacyl ester*, m. 169–70°. Neutral products from the prepn. of III are *3,4,5,4'-tetramethoxystilbene*, yellow, m. 159.5–60.5°, and the *anhydride* of III, m. 143–4°. Reduction of III with PtO_2 at 60–70° gives the corresponding *propionic acid* (IV), m. 95.5–6.5°; *p-phenylphenacyl ester*, m. 94–5°. I (4.9 g.) and 3.7 g. of *p*-$MeOC_6H_4CH_2CN$ with aq. NaOH in EtOH give 8.1 g. of *α-cyano-α-p-anisyl-β-(3,4,5-trimethoxyphenyl)ethylene*, m. 114–15°, with a violet fluorescence. Catalytic reduction gives *β-p-anisyl-γ-(3,4,5-trimethoxyphenyl)propylamine* (V), and *α-cyano-α-p-anisyl-β-(3,4,5-trimethoxyphenyl)ethane*, m. 96.5–7.5° (hydrolysis gives IV). V was characterized as the *N-Ac deriv.* (VI), m. 124.5–5.5° (prepd. by heating with Ac_2O and then refluxing with 10% EtOH-KOH for 4 hrs.), the *p-toluenesulfonyl deriv.*, m. 135–6°, and the *β-naphthalenesulfonyl deriv.*, m. 129.5–31°. In a test on mitosis in the liver of the rat 10 mg. of VI gave a completely abnormal nuclear picture and 1 mg. a slightly modified picture; the fatal dose is 100 mg. Thus it seems that VI has something of the biol. properties of alkaloids contg. condensed ring systems.

C. J. West

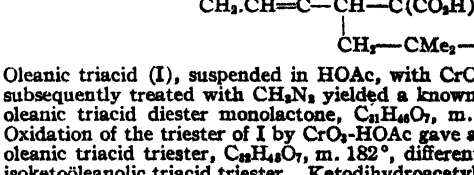


Alkaloids of papaveraceous plants. IV. Alkaloids of Roemeria refracta D. C. Constitution of remerine and synthesis of 2,3-methylenedioxyphenanthrene. R. A. Konovalova, S. Yunusov and A. P. Orekhov. *Bull. soc. chim.* **6**, 1479–85; *J. Gen. Chem.* (U. S. S. R.) **9**, 1507–11 (1939); cf. *C. A.* **33**, 6825[1].—Hofmann degradation of remerine (I) led to the formation of a methylenedioxyphenanthrene (II) of unknown constitution. The synthesis of *2,3-methylenedioxyphenanthrene* (III) was undertaken from 6-nitropiperonal (IV). A mixt. of 20 g. IV (dried at 65–70° and 12 mm.), 16.5 g. of dry $PhCH_2CO_2Na$, and 100 cc. of Ac_2O was heated at 100° for 24 hrs., distd. *in vacuo*, dild. with 200 cc. H_2O and extd. with 700 cc. ether. The ext. was shaken out with 400 cc. of 10% NH_4OH, acidulated with 30% HCl and extd. with ether, yielding 73% (26 g.) of *α-phenyl-6-nitro-3,4-methylenedioxycinnamic acid*, $C_{16}H_{11}NO_6$, m. 199–200°, reduced by NH_3-$FeSO_4$ to the corresponding *6-amino deriv.* (V), m. 207–8°. V (17.4 g.) in 1 l. of 70% alc. was diazotized at 0° by addn. of 200 cc. of 10% H_2SO_4 and 6 g. $NaNO_2$ in 25 cc. H_2O. After stirring for 30 min. at room temp., 35 g. of Cu powder was added. The mixt. was stirred for 2 hrs., filtered the next day, concd. *in vacuo*, crystd. out and extd. with AcOEt, producing 13.4 g. of long, fine needles of *2,3-methylenedioxyphenanthrene-9-carboxylic acid* (VI), $C_{16}H_{10}O_4$, m. 255–6°. A mixt. of 1 g. VI and 3 g. of Cu chromite catalyst in 10 cc. quinoline was boiled for 1 hr. until the evolution of CO_2 ceased completely. The cooled mixt. was dild. with 150 cc. ether and filtered. The filtrate and washings were washed with 10% HCl, 5% NaOH and H_2O. Concn. and recrystn. from alc. gave 0.7 g. of colorless tablets of III, $C_{15}H_{10}O_2$, m. 99–100° (mixed m. p. with II, 50°); *picrate*, m. 149–50°; *di-Br deriv.*, m. 228–9°. The CH_2O_2 group was hydrolyzed by heating 3.4 g. III with 8 g. phloroglucinol and 40 cc. HCl (d. 1.18) in sealed tubes for 5 hrs. at 140–50°. The product was dild. with 40 cc. H_2O, alkalinated with 25% NH_4OH and extd. with ether. The cleavage product was methylated by CH_2N_2 in ether (from 17 g. $MeN(NO)CO_2Et$) and crystd. from alc., yielding 2,3-dimethoxyphenanthrene, m. 130–1° (*di-Br deriv.*, m. 159–60°), and establishing the structure of III. The nonidentity of II and III excludes the positions 2,3 and 6,7 for the CH_2O_2 group in the mol. of I and leaves open the choice between the positions 1,2, 3,4 and 5,6. The acid mother liquors from the sepn. of the HCl salt of I from 70 kg. of *R. refracta*, were alkalinated by 40% NaOH and thoroughly extd. with petr. ether, yielding 4.2 g. of *d*-pseudoephedrine (VII), m. 118–19°, $[\alpha]_D$ 55.55° (HCl salt, m. 182–3°), and 30.5 g. of an oil which, on treatment with alc. $(CO_2H)_2$, gave 12.3 g. of *l*-ephedrine oxalate, m. 239–40°, yielding *l*-ephedrine (VIII), m. 38–9°; HCl salt, m. 216–17°, $[\alpha]_D$ −34.4°. Further working

up of the mother liquors gave final total yields of 16.5 g. VII and 11.2 g. VIII (0.024 and 0.016% of plant wt.). VIII is widely distributed and has previously been reported from *Ephedra*, *Taxus baccata*, *Sida cordifolia*, *Catha edulis* and *Aconitum napellus*, of the Gnetaceae, Taxaceae, Malvaceae, Celastraceae and Renonculaceae, resp. This is the 1st report of the occurrence of VIII in the Papaveraceae. C. R. Addinall

Lupine studies. XV. The alkaloids of Lupinus sericeus Pursh. James F. Couch. *J. Am. Chem. Soc.* **62**, 554–6(1940); cf. *C. A.* **34**, 1024⁶.—The silky lupine, *Lupinus sericeus* Pursh, gives 3.68% of crude alkaloids; extn. with cold Me_2CO and crystn. from hot Me_2CO give spathulatine (I), $C_{32}H_{44}O_6N_4$, with 4.5 mols. H_2O of crystn., m. 233–4° (cf. C., *C. A.* **19**, 289). I and KI in H_2O give the *compd.* $I.3KI$, prisms, m. 260–1°. Passing SO_2 through 2 g. I in 10 cc. H_2O for 2 days gives a brownish oil which has not been identified. Boiling 3 g. I with 10 cc. concd. HCl and 25 cc. H_2O for 6 hrs. gives the *compd.* $C_{16}H_{24}N_2$, a yellow oil, whose *perchlorate* m. 216–17°; it gives a ppt. with $HgCl_2$ and forms a *picrate* m. 214–16°; this is an isomer of spartyrine; the behavior indicates the probability of hydrolysis with subsequent ring closure to form the sparteine skeleton and relates I to the other lupine alkaloids. The Me_2CO mother liquor from I gives a residue which, recrystd. several times from iso-BuAc, gives *nonalupine* (II), $C_{15}H_{24}ON_2$, with 2 mols. of H_2O of crystn., b_{18} 260–70°, m. 91.5–2.5°; dried to const. wt. it m. 235°; recrystn. from H_2O gives the hydrate; $[\alpha]_D^{25}$ −21.3° (EtOH). The $AuCl_3$ *salt*, $II.2HAuCl_4.5H_2O$, yellow needles, m. 177.5–8° (decompn.); *picrate*, m. 185–6°. II does not yield salts with mineral acids or with camphorsulfonic acid; it is not affected by SO_2 in H_2O. Oxidation of II with $KMnO_4$ in cold H_2O gives *hydroxynonalupine*, m. 168.5–70.5°; it is unchanged by SO_2 in H_2O; the *gold salt*, $C_{15}H_{24}O_2N_2.HAuCl_4$, yellow, m. 238–9°. C. J. West

Lupine alkaloids. XVII. Attempted synthesis of allolupinine. K. Winterfeld and F. W. Holschneider. *Arch. Pharm.* **277**, 192–203(1939); cf. *C. A.* **33**, 3799⁸; **34**, 111².—The attempted synthesis failed. The structure of /-lupinine (I) is confirmed by its oxidation (CrO_3) to isomeric *lupinic acids* (*hydrochlorides*, m. 255°, $[\alpha]_D$ 64.25°, and m. 130°, $[\alpha]_D$ −10.25°) (Steinsiek, *Dissertation*, 1928; cf. *C. A.* **22**, 4532). The prepn. of 4 pyridine acids (Winterfeld, *et al.*, *C. A.* **25**, 3005) shows the presence of allolupinine in impure I. 2-γ,γ,γ-Trichloro-β-hydroxypropylpyridine (modified prepn.) and alkali give 2-pyridylacrylic acid (with H_2-Pd-black gives oils), the HCl salt of which is reduced by H_2-Pd-$BaSO_4$ in H_2O to β-2-pyridylpropionic acid (acid chloride could not be obtained). *2-Piperidylpropionyl chloride-HCl*, m. 118–20°, is obtained from the acid-HCl by $SOCl_2$; with $CHNa(CO_2Et)_2$ it gives oils. B. C. P. A.



Diterpenes. XXXVIII. Position of the ring double linkage in *d*-pimaric acid. L. Ruzicka and L. Sternbach. *Helv. Chim. Acta* **23**, 124–31(1940); cf. *C. A.* **33**, 4978¹. —Previous investigations into the structure of *d*-pimaric

(I)

acid (I) have elucidated the skeleton, the position of the Me and CO_2H groups and the probable attachment of a vinyl group in the 14-position. It has been shown that the remaining double linkage is in the 7,8 position in the phenanthrene nucleus, thus establishing the structural formula of I. Oxidation of Me *d*-pimarate (II) with BzO_2H and *o*-$HO_2CC_6H_4CO_2H$ showed that the rate of oxide formation depends on the nature of the solvent used. By variation of the reaction temp. approx. 1 atom O could be introduced into II, but the resulting *monoxide*, $C_{21}H_{32}O_3$, $b_{0.05}$ 180°, gave an amorphous product by loss of 1 mol. H_2O, in all expts. attempting the cleavage of the oxide ring. Further investigations of II were abondoned and attention was directed to the reduced Me dihydro-*d*-pimarate oxide (III). MeMgI (40 g. MeI and 7.5 g. Mg) in ether was treated dropwise with 4 g. III in ether, and the mixt. was refluxed for 48 hrs. and decompd. with iced dil. H_2SO_4. The reaction mixt. was extd. with ether and the reaction product (3.5 g.) was heated with 4–5 g. Se for 6–12 hrs. at 330–45°. The product was extd. with ether and distd. in a high vacuum, yielding 1.5–2.0 g. of crude hydrocarbon which was taken up in alc. and treated with trinitrobenzene. Recrystn. of the products from 2 such dehydrogenations gave 4 g. of crude orange-yellow *deriv.* (IV), m. 143–9°, and 20 more recrystns. yielded 130 mg. of trinitrobenzene compd. (V), m. 173–7°. V was taken up in hot hexane, filtered through Al_2O_3 and the liberated hydrocarbon was eluted. The eluate (60 mg.) was recrystd. from MeOH, yielding 1,7,8-trimethylphenanthrene (VI), $C_{17}H_{16}$, m. 145–6° (all m. ps. cor.), identical with the hydrocarbon from dihydrosclarene (*C. A.* **32**, 4992⁸) and from cassaic acid. VI was converted into the trinitrobenzene deriv., m. 193.0–3.5°, also identical with the corresponding deriv. of the 1,7,8-trimethylphenanthrene from dihydrosclarene and cassaic acid. The mother liquors from the recrystn. of IV gave yellow needles of pimanthrene trinitrobenzene deriv., $C_{32}H_{17}N_3O_6$, m. 158.0–60.5°. III (0.5 g.) in 10–20 cc. anhyd. ether was satd. with dry HCl. Recrystn. of the reaction product from a mixt. of AcOEt and hexane or from hexane gave colorless rods of *Me 8-chloroisodihydro-d-pimarate*, $C_{21}H_{33}ClO_2$, m. 122–5°, converted, by treatment with MeMgI, decompn. of the Grignard product, Se dehydrogenation, recrystn. through the trinitrobenzene deriv. and decompn. of the latter by filtration through Al_2O_3, into VI. III (3.19 g.) in 20 cc. $CHCl_3$ was treated with 1.6 g. Br in 15 cc. $CHCl_3$ at −10°. The reaction mixt. was evapd. *in vacuo* at low temp., treated with hexane and again evapd. down to remove traces of $CHCl_3$. The residue was taken up in ether, treated with MeMgI, dehydrogenated and purified through the trinitrobenzene deriv., yielding VI. From the findings of previous investigations and the results of the above transformations in which a Me group is attached to a C atom of the ring double-linkage it appears to be highly probable that the ethylenic linkage is situated between the 7- and 8-C atoms of the phenanthrene nucleus. C. R. Addinall

Constitution of acid sapogenins. XV. Hederagenin and oleanolic acid. Zenziro Kitasato. *Acta Phytochim.* (Japan) **11**, 1–25(1939); cf. *C. A.* **33**, 1741⁴.—K. now proposes the following to represent the structure of oleanolic acid (R=Me) and of hederagenin (R=CH_2OH).

Oleanic triacid (I), suspended in HOAc, with CrO_3, and subsequently treated with CH_2N_2 yielded a known ketooleanic triacid diester monolactone, $C_{31}H_{46}O_7$, m. 227°. Oxidation of the triester of I by CrO_3-HOAc gave a ketooleanic triacid triester, $C_{33}H_{48}O_7$, m. 182°, different from isoketoöleanolic triacid triester. Ketodihydroacetyloleanolic ester (II) was obtained by treating acetyloleanolic ester (III) in HOAc with perhydrol. II with CrO_3-H_2SO_4-HOAc (IV) gave a diketolactone, $C_{32}H_{46}O_6$, m. 286°, difficultly sol. in ether. Under like conditions III yielded the same compd. A diketohydroxylactone, $C_{32}H_{46}O_7$, decompg. 286°, resulted from the action of IV on ketoacetyloleanolic ester. Ketodiacetylhederagenin ester with IV gave a diketohydroxylactone, $C_{36}H_{48}O_9$, m. 274°. Treatment of diacetylhederagenin ester with IV gave a diketo acid (V), $C_{30}H_{46}O_7$, m. 267°, which gave a green color with H_2SO_4. CH_2N_2 in ether converted V

into the ester (VI) $C_{31}H_{48}O_7.0.5H_2O$, m. 210°. H_2SO_4 gave with it a green color, by warming becoming violet-brown. Ac_2O and NaOAc produced from VI a di-Ac deriv., $C_{35}H_{52}O_9$, m. 229–30°, giving the color reactions of VI and difficultly sol. in ether. When the substance obtained by pptg. the mother liquor from VI with H_2O was acetylated a neutral product, probably a lactone, $C_{34}H_{48}O_8$, m. 285°, resulted, which gave a bright yellow color with hot conc'd. H_2SO_4. Dehydroacetyloleanolic acid with IV yielded an acid, which with CH_2N_2 gave $C_{34}H_{50}O_8$, m. 256°, not identical with acetyloleanolic diacid ester lactone (VII), or its iso form. The pentacarboxylic monolactone tetraester, resulting from VII by oxidation, with 50% MeOH-KOH yielded an isomer, m. 198–200°. Ketoacetyloleanolic acid lactone brominated in HOAc gave $C_{32}H_{47}O_6Br$ (VIII), m. over 300°. The free acid with like treatment produced $C_{32}H_{47}O_4Br$ (IX), m. 240–5° (decompn.). ψ-Ketoacetyloleanolic acid (X) similarly treated yielded $C_{32}H_{45}O_6Br$ (XI), m. 256–7° (decompn.), not identical with the product from the ketolactone. When ψ-ketohederagenin was subjected to similar treatment it gave a monobromolactone (XII) $C_{30}H_{45}O_5Br$, m. 247° (decompn.). VIII with Zn dust and boiling HOAc gave a ketodihydroacetyloleanolic acid, $C_{32}H_{50}O_5$, m. over 300°. This yielded with CH_2N_2 a known ester, $C_{33}H_{52}O_5$, m. 193°. IX by a like reduction gave an acid, $C_{32}H_{52}O_5$, m. 250° (decompn.), which yielded an ester, $C_{33}H_{52}O_5$, m. 272°, $[\alpha]_D^{28.5}$ −39° in $CHCl_3$. X was regenerated from XI by Zn and HOAc. When XII was reduced as above and the product methylated and acetylated it gave the known ψ-ketodiacetylhederagenin Me ester, $C_{34}H_{52}O_2$, m. 222°. VIII with MeOH-KOH (XIII) gave $C_{30}H_{46}O_5$, a lactone, m. 265°. With Ac_2O-NaOAc this yielded neutral $C_{32}H_{48}O_6$, m. 232°. With XIII, XI regenerated X. XII yielded hederagenin by Zn and HOAc reduction. The identity of the synthetic with the natural product was established by the prepn. of the Me esters and the di-Ac derivs. of the same, and by comparing the sp. rotations of all of these substances. G. A. Hill

Osage orange pigments. III. Fractionation and oxidation. M. L. Wolfrom and A. S. Gregory. *J. Am. Chem. Soc.* 62, 651-2(1940); cf. *C. A.* 34, 430[2].—Repeated crystn. of the crude pigments of the osage orange alternatively from xylene and 95% EtOH gives 14.1 g. osajin (I) and 15.8 g. pomiferin (II), indicating that the 2 pigments are probably present in about equal amts. The m.-p. diagram of I and II is given. I and Me_2SO_4 with KOH in Me_2CO give the *di-Me ether* (III), m. 118.5°. Oxidation of III with alk. H_2O_2 gives *p*-$MeOC_6H_4CO_2H$; the tri-Me ether of II gives 3,4-$(MeO)_2C_6H_3CO_2H$. C. J. West

Constituents of certain species of Helenium. III. The ester nature of tenulin. E. P. Clark. *J. Am. Chem. Soc.* 62, 597-600(1940); cf. *C. A.* 33, 6844[9].—Tenulin (I) in 10 cc. Me_2CO, 10 cc. H_2O and 8 cc. 30% H_2O_2, heated to boiling and treated gradually with 5 cc. of 10% NaOH and 10 cc. H_2O, gives 0.57 g. *tenulinic acid* (II), $C_{15}H_{20}O_7$, m. 343–4°, η_α 1.507, η_γ 1.595. Isotenulin (III) gives the same acid. *Me ester* of I, m. 209°. Oxidation of 3 g. of I in 50 cc. Me_2CO and 25 cc. H_2O with 300 cc. 1% aq. $KMnO_4$, followed by addn. of 3.3 g. cryst. $KMnO_4$, gives 1.8 g. of *acetyltenulinic acid* (IV), with 0.5 mol. of H_2O, m. 245° (decompn.); from AcOH it m. 234–5°; η_ω 1.544, η_ϵ 1.552; IV also results from II and Ac_2O in C_5H_5N and on hydrolysis with 10% NaOH it yields II. *Me ester* of IV, m. 259–60°. III (1 g.) in 4 cc. conc'd. H_2SO_4, heated 1 min. at 90°, gives 0.3 g. of *desacetylisotenulin* (V), $C_{15}H_{20}O_4$, m. 255°; the acid mother liquor contains AcOH; V was previously obtained as a by-product in the prepn. of III; Ac_2O yields IV. Dihydrotenulin yields the *desacetyl deriv.*, m. 203°; 10 or 50% aq. KOH may also be used as the hydrolyzing agent; this is not attacked by $KMnO_4$ or alk. H_2O_2 and therefore the formation of II from I involves the double bond of I. Distn. of I gives *pyrotenulin*, $C_{13}H_{16}O_3$, m. 235–6°. I contains a double bond, an Ac_2O group and a HO and a CO group, the last 2 being sterically hindered. *H. quadridentatum* contains helenalin and *H. montanum* contains I. C. J. W.

The preparation of canavanine from Canavalia obtusifolia. M. Damodaran and K. G. A. Narayanan. *Biochem. J.* 33, 1740–2(1939).—Canavanine was readily prepd. in pure form from the seeds of this plant in yields above 20 g. per kg. of fat-free seed meal. The method of Kitagawa and Yamada (*C. A.* 27, 1020) was followed except for a preliminary treatment of the crude canavanine soln. with basic Pb acetate. E. W. Scott

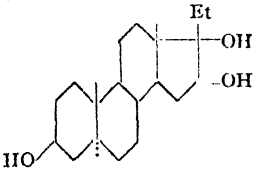
Preparation and degradation of lithocholic acid. Willard M. Hoehn and Harold L. Mason. *J. Am. Chem. Soc.* 62, 569–70(1940); cf. *C. A.* 32, 5847[1].—Me desoxycholate and 1 equiv. of BzCl in C_6H_6-C_5H_5N at 5° give 87–9% of the *3-Bz deriv.* (I), with 0.5 mol. of Et_2O, m. 78–80°; oxidation with CrO_3 in AcOH at 15° gives *Me 3-benzoxy-12-ketocholanate*, m. 94–5°, which is usually not isolated but transformed into the *semicarbazone* (II), m. 160–2° (95% based on I). Reduction of II with Na in EtOH (7 hrs. at 200°) gives 64.6% of lithocholic acid (III). III also results in 62.5% yield by heating the disemicarbazone of Me 3-benzoxy-7,12-diketocholanate with Na in EtOH at 175° for 6 hrs. The degradation of III by the Wieland and Barbier method was carried out as described for desoxycholic acid; data are given for the intermediates since some of these are not given in the literature: 3-acetoxybisnorcholanyldiphenylethylene, m. 158–60°, $[\alpha]_{4461}^{25}$ 75.5° ($CHCl_3$); 3-acetoxypregnanyldiphenylethylene, m. 150–2°, $[\alpha]_{4461}^{25}$ 140° ± 3° ($CHCl_3$); 1,1-diphenylmethyl(3-acetoxyetiocholanyl)ethylene, m. 158–60°, $[\alpha]_{4461}^{25}$ 398 ± 2° ($CHCl_3$); pregnan-3(α)-ol-20-one, m. 148–9°, $[\alpha]_{4461}^{25}$ 129 ± 3° (EtOH); 21-benzalpregnanolone, m. 228–30°, $[\alpha]_{4461}^{25}$ 181 ± 3° (EtOH); 3-acetoxyetiocholanic acid, m. 226–9°, $[\alpha]_{4461}^{25}$ 86.4 ± 3° (EtOH); etiolithocholic acid (IV), m. 270–2°. Oxidation of IV with CrO_3 gives 84% of dehydroetiolithocholic acid, m. 246–8°; *4-Br deriv.*, m. 190–2° (63.5% yield). Corrections for names in the preceding paper are given as follows: 3,12-diacetoxynorcholanyldiphenylethylene should be *3,12-diacetoxybisnorcholanyldiphenylethylene*, 3,12-diacetoxybisnorcholanyldiphenylethylene should be *3,12-diacetoxypregnanyldiphenylethylene* or *3,12-diacetoxyternorcholanyldiphenylethylene* and 3,12-diacetoxyternorcholanyldiphenylethylene should be *1,1-diphenylmethyl(3,12-diacetoxyetiocholanyl)ethylene;* the previous names included 1 C atom in both the ethylene group and the cholanyl radical. C. J. West

Preparation of Δ^5-pregnene-3,17-diol-20-one from 17-ethynyl-Δ^5-androstene-3,17-diol. Homer E. Stavely. *J. Am. Chem. Soc.* 62, 489–91(1940); cf. *C. A.* 33, 1754[4].—17-Ethynyl-Δ^5-androstene-3,17-diol (1 g.), 500 mg. HgO, 0.3 cc. BF_3-Et_2O and 5 cc. $PhNH_2$, allowed to stand at room temp. for 1 week, the $PhNH_2$ removed by steam distn., the residue satd. with H_2S and, after standing overnight, extd. with Et_2O and crystd. from aq. MeOH, give 500 mg. of *Δ^5-pregnene-3,17-diol-20-one anil* (I), m. 148°, $[\alpha]_D^{25}$ −196 ± 2° (12.3 mg. in 2 cc. $CHCl_3$), probably identical with that of Goldberg and Aeschbacher (*C. A.* 34, 1330[7]); $HgCl_2$ may also be used as the catalyst but the above method of purification is preferable to that of G. and A. I seems to be hydrolyzed on standing in aq. MeOH, for after 10 days the mother liquor of I yields *Δ^5-pregnene-3,17-diol-20-one* (II), m. 161–3°; however, the hydrolysis is not complete even on prolonged boiling; apparently an equil. between I and II is established. Sepn. of the II from the mixt. is difficult but after acetylation it is possible to sep. the sparingly sol. acetate of I. II (50 mg.) was acetylated in C_5H_5N and Ac_2O, the solvents removed and the residue heated with 50 mg. $NH_2OH.HCl$, 50 mg. AcOK and 10 cc. EtOH for 2 hrs., giving *3-acetoxy-Δ^5-pregnen-17-ol-20-one oxime* (III), m. 254–6°. Refluxing 2 g. I with aq. MeOH for 28 hrs. gives a mixt. m. over a 30° range; acetylation and crystn. from a large vol. of MeOH give 900 mg. of *3-acetoxy-Δ^5-pregnen-17-ol-20-one anil*, m. 232–4°, $[\alpha]_D^{25}$ −176 ± 2° (13 mg. in 2 cc. $CHCl_3$); the mother liquors yield 520 mg. of *3-acetoxy-Δ^5-pregnen-17-ol-20-one* (IV), m. 196–8°, $[\alpha]_D^{25}$ −61 ± 1.5° (9.2 mg. in 2 cc. $CHCl_3$). Oxidation of IV with CrO_3 (after addn.

of 43 mg. Br to 100 mg. IV) by heating 4 hrs. at 45° gives 3-acetoxydehydroandrosterone, isolated as the semicarbazone. The oxime from IV was identical with III. When sapon. of the Ac group of IV was attempted by heating with MeOH-KOH the alc. so obtained was 3,17-dihydroxy-18-keto-Δ^5-chrysopregnene, previously obtained by the direct hydration of 17-ethynyl-Δ^5-androstene-3,17-diol (S., *C. A.* **33**, 1754[4]). I and IV appear to be sensitive to dil. acid also. The influence of both acid and alkali is being studied more extensively. C. J. West

Sterols. LXXXVII. Cholesterol and sitosterol derivatives. Russell E. Marker and Ewald Rohrmann. *J. Am. Chem. Soc.* **62**, 516–17(1940); cf. *C. A.* **34**, 1681[3].—Oxidation of 2 g. cholesterol (I) in 150 cc. AcOH with 75 cc. *N* aq. $KMnO_4$ and 75 cc. AcOH (6 hrs. at room temp.) gives 1.6 g. of a *cholestan-5-ol-3,6-dione* (II), m. 248–51°, which is probably identical with that obtained by oxidizing with CrO_3 the alk. $KMnO_4$ oxidation product of I. Cholesteryl acetate at room temp. or at 45–50° gives a *3-acetoxy-5-hydroxy-6-ketocholestane*, m. 231–3° (*oxime*, m. 204–6°); there is apparently little tendency for ring B to open between C-5 and C-6. Sitosterol gives similar *compds.*, m. 240° and 251°. Neocholestene and $KMnO_4$ in AcOH give 2,3-cholestanedicarboxylic acid (III), m. 193–5°; β-cholestanol at room temp. gives cholestanone (IV), m. 126–8°; at 55° (3 hrs.) the latter gives a mixt. of III and IV. Heating II and $KHSO_4$ in a high vacuum at 150–80° gives Δ^4-cholestene-3,6-dione, m. 121–3°. Sitosteryl chloride and CrO_3 in AcOH give *7-ketositosteryl chloride* (V), m. 155–6°. Refluxing V with $(iso\text{-}PrO)_3Al$ in iso-PrOH for 12 hrs. gives *7-hydroxysitosteryl chloride*, m. 138–9°; refluxing 200 mg. V and 200 mg. KOH in 9 cc. EtOH and 0.5 cc. H_2O gives *7-ketositosterylene*, pale yellow, m. 106–7°; catalytic reduction of V in Et_2O gives *7-ketositostyl chloride* (VI), m. 128–9°; reduction in AcOH gives sitostyl chloride. VI is not oxidized by CrO_3 by heating 2 hrs. at 60°. **LXXXVIII. Pregnanediols from sarsasapogenin.** *Ibid.* 518–20.—Heating 8 g. of the acetate (I) of sarsasapogenin (II) and 30 cc. Ac_2O in a bomb tube at 195–200° for 10 hrs. and hydrolysis of the residual sirup with EtOH-KOH give 70% of *pseudosarsasapogenin* (III), $C_{27}H_{44}O_3$, m. 171–3°; *di-p-nitrobenzoate*, pale yellow, m. 156.5–9°; III does not yield an acetate. Acidification of the aq. alk. layer from the hydrolysis gives the lactone of II, m. 199–200°; Ac_2O gives the *acetate*, m. 184.5–5.5°. I gives a good yield of III with $(EtCO)_2O$; the only product isolated after heating I in AcOH at 210° for 7 hrs. was a small amt. of II. Heating I with succinic anhydride at 195–200° for 10 hrs. gives a smaller yield of III than does Ac_2O; phthalic anhydride gives no cryst. products; III results on refluxing I with $(PrCO)_2O$ for 8 hrs. Oxidation of III with CrO_3 in about 90% AcOH at room temp. (1 hr.) gives 50–70% of Δ^{16}-pregnene-3,20-dione (IV), m. 200–2° (Masch, *Diss., Danzig*, 1938); *semicarbazone*, m. 310° (decompn.); the acidic fraction is 3-ketoetiobilianic acid. Reduction of IV with Na in EtOH gives pregnane-3(α),20(α)-diol (V), m. 236–9°; *diacetate*, m. 177–9°. Catalytic reduction of IV with Pd-$BaSO_4$ gives pregnane-3,20-dione, m. 117.5–19° (*disemicarbazone*, m. 244° (decompn.)). Reduction of IV with the Adams catalyst in EtOH gives a mixt. of the 3(β),20(β)-, the 3(β),20(α)- and the 3(α),20(β)-isomers; appreciable amts. of other products are formed in these reductions but products other than those of the regular pregnane series have not been isolated. The transformation of II into IV indicates the presence of a C-21 Me group and of an HO group at C-3. **LXXXIX. Reactions of pseudosarsasapogenin.** *Ibid.* 521–5.—Pseudosarsasapogenin (I) is very readily oxidized by SeO_2. It reacts with Br but definite cryst. products have not been isolated. I does not react with $H_2NNHCONH_2$. AcOH. I (2.5 g.) and 15 cc. Ac_2O, refluxed for 30 min., the Ac_2O removed *in vacuo*, the residue taken up in 60 cc. AcOH and heated on the water bath while 5 g. CrO_3 in 50 cc. 80% AcOH is added during 1 hr., 10 cc. EtOH added, the soln. evapd. to 50 cc., H_2O added, the ppt. taken up in ether and the soln. washed with 3% NaOH and H_2O, the NaOH soln. heated on the water bath for 20 min., cooled and acidified, give 600 mg. of 3(β)-hydroxyetiobilianic acid (II), m. 220–2°; hot Ac_2O gives the *acetate anhydride*, m. 204.5–6.5°. The ether soln. gives a *compd.* $C_{23}H_{34}O_4$, m. 284–7°. Oxidation of acetylated I with CrO_3 at room temp. gives II and the *acetate* (III) of Δ^{16}-pregnen-3(β)-ol-20-one, m. 144–6°; the *semicarbazone* of III m. 250–2°; the filtrate from III on hydrolysis gives some II, indicating that some of the II is present as the anhydride. Oxidation of III with CrO_3 in AcOH (16 hrs. at room temp.) gives II. Hydrolysis of III with EtOH-KOH (refluxing 10 min.) gives *Δ^{16}-pregnen-3(β)-ol-20-one*, with 1 mol. of EtOH, m. 207–9° (*semicarbazone*, m. 240° (decompn.)); oxidation with CrO_3 gives Δ^{16}-pregnene-3,20-dione (IV). Reduction of III with Na in boiling EtOH gives pregnane-3(β),20(α)-diol; the Adams catalyst yields pregnane-3,20-dione after oxidation with CrO_3. Catalytic reduction of I in AcOH, EtOH or acidic EtOH yields *dihydropseudosarsasapogenin* (V), m. 168–70°; *diacetate* (VI), m. 95–7°; *di-p-nitrobenzoate*, m. 196–7.5°; V does not react noticeably with SeO_2; in AcOH it absorbs Br slowly. VI is also formed by catalytic reduction of acetylated I. Oxidation of V with CrO_3 in AcOH gives IV and a *diketo acid* (VII), $C_{27}H_{42}O_4$, m. 233–6°; *disemicarbazone*, m. 209° (decompn.); *Me ester*, m. 85–7°. Further oxidation of VII gives IV. Oxidation of VI with CrO_3 in AcOH at room temp. or at 90° gives II; no reaction occurs below 20°; the neutral product at room temp. is III. The presence of an Ac group at C-27 hinders the oxidation of a reactive group at C-22. Suggested formulations for I are given. **XC. Oxidation products of sarsasapogenin. Pregnane-3,16,20-triol.** Russell E. Marker, Ewald Rohrmann, Harry M. Crooks, Eugene L. Wittle, Eldon M. Jones and D. L. Turner. *Ibid.* 525–7[5].—Refluxing 1 g. sarsasapogenin acetate (I), 4 g. $K_2S_2O_8$, 150 cc. 90% AcOH and 1 cc. concd. H_2SO_4 for 2 hrs. and hydrolyzing the residue with EtOH-KOH gives 20–40% of *pregnane-3(β),16,20-triol* (II), m. 223–6°; *benzoate*, m. 185–7°; *triacetate*, m. 108–11°. Oxidation of the epi isomer of I gives the *3(α)-isomer* of II, m. 206–7°; *benzoate*, m. 153–5°. Mild oxidation of II with CrO_3 and reduction with Na in EtOH give pregnane-3(α),20(α)-diol. The acidic fractions have not been investigated. **XCI. Oxidation of the diacetate of cholestane-3,6-diol.** Russell E. Marker, John Krueger, John R. Adams, Jr., and Eldon M. Jones. *Ibid.* 645–6.—Oxidation of the diacetate of cholestane-3,6-diol with CrO_3 in AcOH gives a mixt. of allohyodesoxycholic acid (I), m. 280° (Me ester, m. 181°), and 6-hydroxyisoandrosterone, m. 205°. I, transformed into the Me ester by refluxing with 1% MeOH-HCl for 1 hr. and treated with 16 mols. of PhMgBr (refluxing 2 hrs. in Et_2O-PhMe and then heating overnight on the steam bath with PhMe alone), the carbinol acetylated, dehydrated and oxidized with CrO_3, gives *norallohyodesoxycholic acid*, m. 225°. Bisnorhyodesoxycholic acid (part LXXXIV) (15 g.) with CrO_3 in AcOH at 12–15° for 25 min., gives 12 g. *3,6-diketobisnorcholanic acid*, m. 185° (*Me ester*, m. 170°); refluxing the acid with AcOH contg. a little HCl for 45 min. gives *3,6-diketobisnorallocholanic acid* (II), m. 244° (*Me ester*, m. 211°); catalytic reduction (Adams catalyst) in AcOH of 5.5 g. II gives 5 g. *bisnorallohyodesoxycholic acid*, m. 259° (*Me ester*, m. 233°); *diacetate*, m. 115° (*Me ester*, m. 135°). **XCII. The preparation of neotigogenin from sarsasapogenin.** Russell E. Marker and Ewald Rohrmann. *Ibid.* 647–8.—Dibromosarsasapogenone (5 g.) and 50 cc. C_5H_5N, refluxed 8 hrs., give a *compd.*, $C_{32}H_{45}O_3NBr_2$, m. 235° (decompn.) (probably a pyridinium salt), and 2.2 g. *bromo-Δ^4-dehydrosarsasapogenone* (I), m. 185–8° (decompn.). Reduction of 2 g. of I with Na in boiling EtOH and sepn. of the isomers with digitonin give 600 mg. of neotigogenin, m. 198–200° (*acetate*, m. 173–5°). This indicates that tigogenin, chlorogenin and diosgenin differ from sarsasapogenin in the side-chain configuration and are of the "isosarsasapogenin configuration." The stability of gitogenin and digitogenin to aq. EtOH-HCl suggests that these likewise have the same configuration. **XCIII. Epipseudosarsasapogenin, pseudosarsasapogenone and pseudochlorogenin.** Russell E. Marker, Ewald Rohrmann and Eldon M. Jones. *Ibid.* 648–9.—Epi-sarsasapogenin (m. 205–7°) forms an *acetate*, m. 191–3°;

heating 2 g. with 20 cc. Ac_2O at 200° for 10 hrs. and hydrolysis give *epipseudosarsasapogenin* (I), m. 211–13°; the Adams catalyst in AcOH (17 hrs. at room temp.) gives the *dihydro deriv.*, m. 135–7°. Oxidation of I with CrO_3 in AcOH gives 16-pregnene-3,20-dione (II). Heating 4 g. sarsasapogenone and 30 cc. Ac_2O at 200° for 10 hrs., followed by hydrolysis, gives *pseudosarsasapogenone* (III), m. 165–6°; *semicarbasone*, m. 215–16° (decompn.). Oxidation of III gives II. Isosarsasapogenin acetate (3.3 g.) and 25 cc. Ac_2O, heated at 195° for 9 hrs., give 1.7 g. of pseudosarsasapogenin. Dihydrosarsasapogenin is unchanged after heating with Ac_2O. Heating chlorogenin (2.5 g.) and 30 cc. Ac_2O at 200° for 10 hrs. gives 1.4 g. of *pseudochlorogenin*, m. 268–70°; *dihydro deriv.*, m. 269–72° (*triacetate*, m. 149–52°). **XCIV. Persulfate oxidation of allopregnane derivatives.** Russell E. Marker, Ewald Rohrmann, Eugene L. Wittle, Harry M. Crooks, Jr., and Eldon M. Jones. *Ibid.* 650–1.—Oxidation of allopregnan-20-one with $K_2S_2O_8$ in AcOH-H_2SO_4 gives a mixt. of carbinols, which could not be sepd. and etioallocholanic acid, m. 228–30° (Me ester, m. 141–3°). Allopregnan-3(β)-ol-20-one with $K_2S_2O_8$ gives a mixt. of carbinols, oxidized to androstanedione, m. 130°, and as the acidic fraction 3(β)-hydroxyetioallocholanic acid, m. 250–2°.



C. J. West

Catalytic hydrogenation of several 5,6-dibrominated derivatives of the sterol group. J. Décombe and J. Rabinowitch. *Bull. soc. chim.* **6**, 1510–22(1939).—The addn. of a mol. of halogen to the double bond of cholestene (I) or of cholesterol (II) produces 2 asym. C atoms and 4 possible isomers, 2 from the cholestane and 2 from the coprostane skeleton. An attempt has been made to fix the steric structure of several such dihalogenated derivs. by a study of the products of catalytic hydrogenation. Bromination of I in $CHCl_3$ and recrystn. of the product from alc.-ether gave cholestene dibromide (β-form) (III), m. 106°. The alc.-ether mother liquor yielded a small amt. of the α-form (IV), m. 148°, in rhombohedrons, on recrystn. from ether and petr. ether. Reactions involving the debromination of III bring about a partial stereomutation resulting in the formation of the stable IV. III (20 g.) in 200 cc. petr. ether was irradiated with ultraviolet light for 240 hrs. and evapd. down. The residue was taken up in acetone, yielding 50% of felted needles of form γ (V), m. 116–17°. V appears to be a relatively stable intermediate in the transposition of III into IV under the action of ultraviolet light. I in anhyd. ether was chlorinated with a slight excess of Cl in CCl_4. The reaction mixt. was concd. and treated with AcOH. The ppt. was recrystd. from a mixt. of ether and alc., yielding brilliant leaflets of cholestene dichloride (VI), m. 121–2°. Addn. of 25 g. Br in 250 cc. AcOH to 50 g. II in 500 cc. ether and recrystn. of the quant. yield of crystals from acetone gave cholesterol dibromide (VII), m. 113–5°, $[\alpha]_{578}$ −50°, $[\alpha]_{546}$ −54.1°, $[\alpha]_{436}$ −104.1° (*c* 0.5% in $CHCl_3$). II (20 g.) in 250 cc. CCl_4 was chilled and treated portionwise with a 5% excess of 12% Cl in CCl_4. After 1 hr. at room temp. the CCl_4 was removed at 40° *in vacuo*. The viscous residue was dissolved in ether and dild. with 4 vols. of warm alc. The cryst. product obtained on cooling was recrystd. from boiling alc., yielding 40% of cholesterol dichloride (VIII), m. 136–7°, $[\alpha]_{578}$ −35.3°, $[\alpha]_{546}$ −40°, $[\alpha]_{436}$ −69.6° (*c* 2% in $CHCl_3$). Oxidation of 10 g. VII in 250 cc. AcOH with 2.5 g. CrO_3 in 5 cc. H_2O and crystn. of the product from acetone gave unstable 5-cholestenone dibromide (IX), m. 80°, $[\alpha]_{578}$ −55.8°, $[\alpha]_{546}$ −60°, $[\alpha]_{436}$ −122.5° (*c* 1% in $CHCl_3$). Similar oxidation of VIII (23 g.) produced *5-cholestenone dichloride* (X), $C_{27}H_{44}Cl_2O$, m. 110–11°, $[\alpha]_{578}$ −30°, $[\alpha]_{546}$ −35°, $[\alpha]_{436}$ −60° (*c* 1% in $CHCl_3$). The dihalogen derivs. (0.01 or 0.005 mol.) in 50–200 cc. of pure ether (for catalysis) were hydrogenated in the presence of PtO_2 and 20 cc. H_2O. IV was not reduced and III and V yielded I and HBr. VI was not reduced. Hydrogenation of VII eliminated 2 atoms of Br and produced II. Similarly reduction of IX gave cholestenone and HBr. Thus the dibromides lose their Br atoms and regenerate the initial ethylenic compd. Hydrogenation of VIII with 1 vol. of H gave 6-chlorocholestanol (XI), $C_{27}H_{47}ClO$, m. 136–7°, $[\alpha]_{578}$ −16.6°, $[\alpha]_{546}$ −21°, $[\alpha]_{436}$ −33.3° (*c* 1% in $CHCl_3$). Absorption of 2 vols. of H gave β-cholestanol, m. 140–1°. Thus VIII may be regarded as a 5,6-dichlorocholestanol. The addn. of 1 vol. H to X gave an impure VIII whereas the absorption of 2 vols. H gave a monohalogenated alc. (XII), $C_{27}H_{45}ClO$, m. 94°, $[\alpha]_{578}$ −16.6°, $[\alpha]_{546}$ −25°, $[\alpha]_{436}$ −42°. On further reduction with 3 vols. H a definite formation of β-cholestanol indicates that X is a 5,6-dichlorocholestanone and that XII is a 6-cholorocholestanol, differing from XI in its spatial disposition. The reduction of the chlorinated compds., by yielding satd. monohalogen derivs. and cholestane derivs. fixes the nature of the C skeleton.

C. R. Addinall

Constituents of the adrenal cortex and related compounds. Diazoprogesterone. T. Reichstein and J. v. Euw. *Helv. Chim. Acta* **23**, 136–8(1940); cf. *C. A.* **34**, 1029[8].—Dehydrogenation of secondary alcs. to the corresponding ketone according to Oppenauer can be carried out at room temp. by allowing the reaction to continue for 2–3 weeks. The yields are just as good but the variation permits the handling of heat-sensitive compds. A mixt. of 200 mg. of 21-chloropregnenolone, 500 mg. of freshly sublimed (*tert*-BuO)$_3$Al (I), 12 cc. abs. benzene and 6 cc. acetone was kept at room temp. for 20 days in a sealed ampoule. The gelatinous product was taken up in ether and the washed and dried ext. was evapd. down. Crystn. of the residue from abs. ether gave 145 mg. of 21-chloroprogesterone (II), m. 202–4° (all m. ps. cor.). Similarly dehydrogenation of 200 mg. of 21-diazo-5-pregnan-3-ol-20-one (*C. A.* **31**, 7880[2]) gave 136 mg. of *21-diazoprogesterone* (III), $C_{21}H_{28}N_2O_2$, m. 182–4°, of which 20 mg. was converted by dry HCl in ether into 14 mg. II. Boiling 20 mg. III with 0.5 cc. of purest anhyd. AcOH for 3 min. gave 10 mg. of desoxycorticosterone acetate, m. 158–9°. III was converted into free desoxycorticosterone by heating with dil. H_2SO_4, thus confirming the constitution assigned. **XXXII. Three stereoisomeric allopregnane-3 β,17,20-triols.** H. Reich, M. Sutter and T. Reichstein. *Ibid.* 170–80.—Dehydration of allopregnane-3 β,17α-diol monoacetate (I) with anhyd. $CuSO_4$ gave a crude dehydrated product (II) which on hydroxylation with OsO_4 gave some substance J and an isomeric triol (*C. A.* **33**, 6329[1]). A more uniform dehydration was obtained by the procedure of Butenandt and co-workers (*C. A.* **31**, 5862[8]). A mixt. of 10.5 g. I and 4.4 cc. $POCl_3$ in 44 cc. anhyd. pyridine was heated at 135° for 45 mins., poured into 176 cc. concd. HCl and ice, and extd. with ether, yielding 9.5 g. of crude product. Crystn. from 100 cc. alc. gave 5.1 g. of colorless needles, m. 114–17°, 1.34 g. of less pure crystals, m. 104–12°, and further yields by chromatography of the mother liquor. Recrystn. of the material from MeOH gave II, 3 β-acetoxyallo-17-pregnene, $C_{23}H_{36}O_2$, m. 120.0–1.5°, of which 500 mg. was sapond. with 5% KOH in MeOH to give 463 mg. of 3 β-hydroxyallo-17-pregnene, m. 136–7°. Hydroxylation of 4.9 g. II, m. 114–17°, in 92 cc. abs. ether was carried out by standing with 4 g. OsO_4 in 23 cc. abs. ether for 3.5 days at room temp. The mixt. was evapd. down, taken up in 150 cc. alc. and treated with 25 cc. of 2 *N* NaOH and 20 cc. of 40% HCHO for 12 hrs. at room temp. The mixt. was boiled for 30 min., filtered, dild., satd. with CO_2 and concd. *in vacuo*. The residue was shaken out with much AcOEt and finally with ether. The washed and dried united ext. gave 4.7 g. of crude product on evapn. *in vacuo*. The material was acetylated with 20 cc. of dry pyridine and 10 cc. Ac_2O at room temp. for 16 hrs. and at 60° for 1 hr. The soln. was evapd. *in vacuo*, extd. with ether, concd. and pptd. with pentane, yielding 2 g. of crystals. Sublimation at 170° and 0.03–0.05 mm. left very little residue. The sublimate was recrystd. from a mixt. of ether and pentane, yielding, as main product, substance J diacetate (III), m. 159–61°, and a new *triol diacetate* (IV), m. 135–6°. The non-cryst. material from the mother liquors was sublimed in a high vacuum, giving a thick colorless resin at 0.02 mm. and 170–200°. Recrystn. from ether-pentane yielded III

and IV. The mother liquors (V) also produced 535 mg. of a cryst. mixt. (VI), m. 170–222°. VI was dissolved in 1 part of benzene and 9 parts of pentane and chromatographed over a 16-g. Al_2O_3 column. Elution with various benzene-pentane mixts., benzene, benzene-ether mixts., ether and acetone, recrystn. of each eluated product from ether-pentane and washing with pentane gave 25 fractions of which 3–5 gave the "*first by-product*" (VII), m. 160–1°; 8–11 yielded IV; 12–14 gave III; 16–21, by repeated recrystn. from ether-pentane and from ether produced III and substance O diacetate (VIII), m. 250–1°; and 22–25 gave crystals, m. 169–94°, which were discarded. Similar treatment of V (1.76 of oily material) produced fractions contg. II, a "second by-product" (IX), m. 207–9°, VII, III and VIII. In all, the following yields were obtained: III, about 2 g.; IV, 0.85 g.; VII, 135 mg.; VIII, 15–20 mg.; and IX, 15–20 mg. IV, $C_{23}H_{40}O_5$, $[\alpha]_D^{25}$ −18.2 ± 1°, $[\alpha]_{5461}^{25}$ −21.75 ± 1°, was sapond. with 5% KOH in MeOH and the product from 100 mg. was recrystd. from dil. MeOH, yielding 86.2 mg. of the free *allopregnane-3β,17,20-triol* (X), m. 202–15°, $[\alpha]_D^{25}$ −16.7 ± 2°, $[\alpha]_{5461}^{25}$ −18.7 ± 2°. Degradation of 20 mg. X in 1 cc. MeOH with 30 mg. HIO_4 in 4 cc. H_2O and 1.5 cc. MeOH for 17 hrs. at room temp., decompn. with 10 drops of $NaCO_3$, evapn., extn. with ether and concn. gave crystals, m. 169–74°, which on recrystn. from dil. MeOH yielded *trans*-androsterone, m. 172.5–4.0°, identical with an authentic sample. The 2 isomeric allopregnanetriols, substances J and O, have different configurations at the 17-position. Since substance J and substance O differ only in the disposition of the OH group at C atom 20, the 2 isomeric triols belong to the 17 α and 17 β series and thus hydroxylation of substances of the type of II does not give 17β-HO derivs. exclusively as previously stated. Sublimation of VIII in high vacuum and recrystn. from ether gave colorless needles, $C_{28}H_{40}O_5$, m. 250–1°, identical with a sample from adrenal cortex. Recrystn. of VII from ether-pentane yielded crystals of a *diacetate*, $C_{28}H_{40}O_5$, $[\alpha]_D^{25.5}$ −60.9 ± 2°; $[\alpha]_{5461}^{26.5}$ −74.5 ± 2°; sapond. to give prisms of the free *triol*

(XI), m. 234–40°, $[\alpha]_D^{25}$ −28.5 ± 2°, $[\alpha]_{5461}^{25}$ −32.5 ± 3°. Degradation of XI with HIO_4 failed to produce *trans*-androsterone. Oxidation with CrO_3 converted XI into an *acid*, $C_{21}H_{32}O_4$, m. 195–7°, showing that it may have 2 adjacent OH groups of which 1 is tertiary. It is possible that XI is formed from an impurity of II, contg. stable ring double bonds. Recrystn. of IX from ether-pentane gave fine needles of the *monoacetate*, $C_{23}H_{34}O_5$, m. 207–9°, sapond. to give needles of the *triol* (XII), m. 197–9°. Oxidative degradation of XII with CrO_3 in AcOH produced a *neutral product*, $C_{19}H_{28}O_2$, m. 230°, which was not identical with androstanedione. Thus despite earnest search, the 4th allopregnane-3β,17,20-triol was not found. C. R. Addinall

Liquid hydrocarbon products from gaseous olefins. Walter Flemming and Wilhelm Baumeister (to I. G. Farbenind. A.-G.). U. S. 2,185,405, Jan. 2. Gaseous olefins such as C_3H_6, are subjected to polymerization in the presence of an anhyd. halide of Al, as a polymerization catalyst, and of a halogen hydrocarbon having a double C linkage, such as perchloroethylene, as a dispersion agent, suitably at 0–20°.

Polymerizing olefin hydrocarbons. Melvin M. Holm and Wm. H. Shiffler (to Standard Oil Co. of Calif.). U. S. 2,186,021, Jan. 9. A catalyst is used comprising a thin film of an active polymerizing agent such as H_3PO_4 carried on the surface of particles of a nonporous inert solid material such as quartz. U. S. 2,186,022 relates to the use of a catalyst of generally similar character for effecting reactions such as *isomerization* without polymerization.

Preparing mixtures of carbon monoxide and hydrogen suitable for use in catalytic synthesis. Geo. Roberts, Jr. (to M. W. Kellogg Co.). U. S. 2,185,989, Jan. 2. An arrangement of app. is described, and a method of prepg. a mixt. of CO and H for catalytic synthesis including the steps of desulfurizing methane to remove objectionable S compd., subjecting a CO_2-bearing gas to absorption by an absorption menstruum selective to CO_2 in an absorption zone, stripping the absorbed CO_2 from the absorption menstruum by means of the CH_4 removed from the desulfurizing zone and thereby forming a mixt. of CO_2 and CH_4, generating the desired synthesis gas comprising CO and H by heating the mixt. of CO_2 and CH_4 in a synthesis gas generating zone at temps. above 815° in the presence of a catalyst.

Removing alcohol from commercial amyl acetate. A. L. Likhtman. Russ. 51,928, Nov. 30, 1937. Amyl acetate is treated with concd. H_2SO_4, then petroleum ether. The upper layer of amyl acetate is sepd. from the lower H_2SO_4 layer, the H_2SO_4 layer is extd. with petroleum ether, the ext. is added to the amyl acetate soln., and this soln. is washed with Na_2CO_3, dried and distd.

Methyl ketones. B. N. Dashkevich. Russ. 51,926, Nov. 30, 1937. Ketene is treated with an ether soln. of an organomagnesium bromide.

Esters of aliphatic polyhydric nitro alcohols. Walter E. Gloor (to Hercules Powder Co.). U. S. 2,185,297, Jan. 2. Esters suitable for use in plasticizing cellulose acetate and other cellulose derivs., etc., are formed from trimethylolnitromethane or dimethylolnitroethane by reaction with propionic or butyric acid or anhydride (suitably in the presence of $ZnCl_2$ or other esterification catalyst and at a temp. of about 100–150°). Trimethylolnitromethane triacetate b_{5-10} 160–70°. Trimethylolnitromethane tripropionate b_{5-10} 170–185°. Trimethylolnitromethane tributyrate b_{5-10} 185–205°. Dimethylolnitroethane diacetate b_{5-10} 152–160°. Dimethylolnitroethane dipropionate b_{5-10} 150–165°. Dimethylolnitropropane diacetate b_{5-10} 135–158°. Tri-α-ethylolnitromethane triacetate also is mentioned.

Fatty acid mono-esters of monochlorohydrin. I. G. Farbenindustrie A.-G. Brit. 509,072, July 11, 1939. These are produced by causing aliphatic monocarboxylic acids having at least 4 C atoms to react with epichlorohydrin in the presence of catalysts of the Friedel-Crafts' type.

Esters of methacrylic acid. Herman A. Bruson and Robert N. Washburne (to Röhm & Haas Co.). U. S.

2,184,934, Dec. 26. For converting an ester of α-hydroxy-isobutyric acid, such as the Et or Me ester, to the corresponding ester of methacrylic acid its vapor is brought into contact with a dehydrating catalyst such as a mixt. of Al phosphate and Mn or Mg phosphate at a temp. of about 325–425°.

Preparing sulfo carboxylic ester salts. Frank J. Cahn and Morris B. Katzman (to Emulsol Corp.). U. S. 2,185,455, Jan. 2. A method of prepg. esters of alcs. contg. at least 8 C atoms and sulfocarboxylic acids contg. less than 8 C atoms, such as lauryl sulfoacetate, the H of the sulfonic groups of which is replaced by an org. nitrogenous base, involves the reaction of an org. nitrogenous base, such as triethanolamine, an ester of an alc. contg. at least 8 C atoms, and a sulfocarboxylic acid contg. less than 8 C atoms the H of the sulfonic group of which is replaced by a metal cation, such as lauryl K sulfoacetate, and an acid such as tartaric acid which reacts with the metal salt to form a less sol. salt which is pptd., and sepg. the resulting ppt.

Halogenated amides and imides of cyanuric acid and polymers of cyanamide. Irving E. Muskat and Albert G. Chenicek (to Pittsburgh Plate Glass Co.). U. S. 2,184,888, Dec. 26. Products of this type in which a substantial amt. of the contained halogen is present as active halogen are suitable for use as *bleaching* and *sterilizing agents* and may, e. g., be obtained by bromination or iodination of melamine or dicyandiamide.

Epithio alkanes. N. V. de Bataafsche Petroleum Maatschappij. Brit. 508,932, July 7, 1939. These are obtained by causing halothiols, in which the halogen atom and the thiol group are bound to C atoms adjacent to each other, to react with substances capable of binding H halides, the reaction medium remaining neutral or practically so, e. g., at pH 5.5–11.5. Thus, chloro-2-ethanethiol is stirred with $NaHCO_3$ and H_2O, a uniform stream of CO_2 escaping and the temp. remaining practically const.; after completion of the reaction, the mixt. is distd. under reduced pressure to obtain a distillate consisting of an aq. bottom layer and a top layer contg. epithioethane, the latter, after sepn., being dried over $CaCl_2$ and, after introduction of H_2S for stabilization, fractionated.

Substituted 3-aminopyrenes. Martin Corell, Heinrich Vollmann and Hans Becker (to General Aniline Works). U. S. 2,185,661, Jan. 2. By the use of solvents such as alc., benzene, toluene, xylene or pyridine, sepn. is effected of assocd. isomeric 3,8- and 3,10-disubstituted pyrenes in which one of the substituents is an amino group and the other may be amino, acetylamino, acetyl, Cl or carboxyl. Various examples with details are given, including the production of 3-amino-8-chloropyrene, m. 142°, 3-aminopyrene-8-carboxylic acid, etc.

***N*-Substituted lutidones.** Albert B. Boese, Jr. (to Carbide and Carbon Chemicals Corp.). U. S. 2,185,243, Jan. 2. For prepg. an *N*-substituted lutidone such as *N*-phenyllutidone, a primary amine such as aniline is treated with diacetylacetone in the presence of a volatile water-insol. org. solvent such as benzene which is inert to the reactants (suitably by refluxing for 2 hrs.). Details are given of the production of *N*-phenyllutidone, *N*-β-naphthyllutidone, *N*-benzyllutidone, *N*-hydroxyethyllutidone, *N*-cyclohexyllutidone and *N*-methyllutidone.

Separation of thiophenols from alkylphenol mixtures. Daniel B. Luten, Jr. and Samuel B. Thomas (to Shell Development Co.). U. S. 2,184,928, Dec. 26. An arrangement of app. is described, and a process involving extg. the mixt. in countercurrent with aq. NH_3 having a concn. not less than about 10% in an amt. substantially in excess of that which is equiv. to the content of thiophenols in the mixt., so as to produce 2 layers only, an alkylphenol layer and a layer of aq. NH_3 contg. thiophenols, and sepg. these layers.

***N*-Alkylacridines.** N. S. Drozdov. Russ. 51,927, Nov. 30, 1937. 9-Phenoxyacridine or its derivs. are heated with an ester of *p*-toluenesulfonic acid, and the product is sepd. in the usual manner.

Purifying pyridine bases. A. A. Kharkharov. Russ. 55,844, Oct. 31, 1939. An aq. soln. of a diazonium salt is added to the pyridine base; the base is then sepd. by known mthods from the azo dye formed by the admixt.

Sterol derivatives. Russell E. Marker (to Parke, Davis & Co.). Brit. 509,063, July 11, 1939. A 7-ketocholesteryl halide is reduced to the corresponding 7-hydroxycholestyl halide (I), which by further reduction gives 7-hydroxycholestane capable of oxidation to 7-ketocholestane. The 1st reduction may be a direct and complete catalytic hydrogenation, or a partial reduction without use of H to 7-hydroxycholesteryl halide followed by a further reduction of the latter at its unsatd. double bond to give I. Both the direct 1-step reduction and the reduction by way of 7-hydroxycholesteryl halide give α-cholestyl halide as a 2nd product of the reduction. The 7-hydroxy group of I may be oxidized to give a 7-ketocholestyl halide. Cf. *C. A.* **33**, 2909[5].

Polymeric basic compounds. I. G. Farbenindustrie A.-G. Brit. 509,012, July 6, 1939. These are made by causing a polymerization compd. of high mol. wt. that contains free alc. OH groups, e. g., polyvinyl alc. (I) or a deriv. thereof contg. free alc. OH groups, or that may be transformed into such a compd. to react with an amino aldehyde or an amino ketone, e. g., by heating them together in the presence of a catalyst of strongly acid reaction. Solvents or diluents may be present. Among examples, (1) pulverized I is suspended in MeOH, *p*-dimethylaminobenzaldehyde sulfate introduced into the suspension with stirring and the mixt. heated 2.5 hrs., the acetalization being accelerated by the addn. of a little H_2SO_4; the greater part of the product seps. on cooling, sepn. being completed by addn. of further MeOH, and the highly elastic resinous mass is washed with MeOH and dried; it does not dissolve in org. solvents but, being the sulfate, readily dissolves in H_2O from which the free polymeric amino compd., which is sol. in various org. solvents, e. g., glacial AcOH, and, on addn. of acid, e. g., HCl, H_2SO_4, HCOOH, in H_2O, may be pptd. by alkali; (2) I is dissolved in concd. HCl and 1,2-dimethylindole-3-aldehyde introduced into the soln. at 10–20° with stirring; after 8 hrs. the viscous soln. is neutralized with dil. NaOH soln., the condensation product being obtained as red-brown flakes that are sol. in mineral acid and AcOH and swell in tetrahydrofuran or in mixts. of Me_2CO and H_2O.

Benzylideneaniline compounds. Frederick H. Kranz (to National Aniline and Chemical Co.). U. S. 2,185,854, Jan. 2. In the production of a compd. such as a benzylideneaniline by the reaction of CH_2O with a *p*-*N*-alkylaminonitrosobenzene and an *N*-alkylaminobenzene compd. free from *p*-substituents, to form the corresponding benzylideneaniline, the nitroso compd. and CH_2O at least are added, at a temp. below reaction temp., to the hot reaction zone wherein reaction of the 3 reactants is effected.

Aminoanthraquinone compounds. James Ogilvie and Richard S. Wilder (to National Aniline & Chemical Co.). U. S. 2,185,709, Jan. 2. A process for converting a leucoaminoanthraquinone compd. contg. an amino radical in the 1-position of the anthraquinone nucleus and in the 4-position a radical selected from the group consisting of amino radicals and the hydroxyl radical to the corresponding aminoanthraquinone compd. involves oxidizing the leucoaminoanthraquinone compd. with an aromatic nitroso compd. whereby the corresponding aminoanthraquinone compd. is obtained.

Compounds of the polyhydrocyclopentanophenanthrene series. I. G. Farbenindustrie A.-G. Brit. 508,804, July 5, 1939. These are made by oxidizing or reducing, by means of an Al alcoholate in the presence of substances that accept or yield H, a deriv. of a 3-hydroxy- or 3-oxopolyhydrocyclopentanophenanthrene that has a side chain contg. a basic nitrogenous group at the C atom in 17-position. Among examples, (1) 3-hydroxyternorcholenylamine and tertiary Al butylate (I) are boiled under reflux in anhyd. C_6H_6 and Me_2CO, the soln. being then poured into H_2O, NaOH soln. added to the colloidal mixt. until the pptd. $Al(OH)_3$ dissolves and the whole extd. with Et_2O; the 3-oxoternorcholenylamine may be pptd.

from the dry Et_2O ext. by H_2SO_4 in Et_2O, and (2) a mixt. of 3-hydroxyandrostenemethylketimine, I, C_6H_6 and Me_2CO is boiled 11 hrs. under reflux and then shaken 24 hrs. with 0.5 *N* H_2SO_4 to hydrolyze the ketimine group in the oxidation product, the C_6H_6 soln. is sepd., dried and evapd. under reduced pressure; by crystn. of the org. residue from Et_2O and aq. alc., the progesterone is obtained. Cf. *C. A.* **33**, 7316[5,6]. 1

Stabilized alkali metal alcoholates. Geo. L. Cunningham and Richard S. Robinson (to Mathieson Alkali Works). U. S. 2,185,247, Jan. 2. Stabilization of an alcoholate such as Na ethylate is effected by adding about 2% or less of a catalytic amine, amine hydrochloride or amide, such as ethylenediamine, free from any substituent groups exerting a proöxidant effect. 2

Purifying tritolyl phosphate after use for extraction of phenols. Hinrich Havemann and Karl Smeykal (to I. G. Farbenind. A.-G.). U. S. 2,184,697, Dec. 26. See Ger. 670,273 (*C. A.* **33**, 2912[2]). 3

Stabilizing sulfides such as ethylene sulfide. Willem Coltof and Siegfried L. Langedijk (to Shell Development Co.). U. S. 2,185,660, Jan. 2. Deterioration under ordinary storage and transportation conditions is inhibited by the addn. of H_2S, an alkyl mercaptan or an alkyl sulfide.

Dialkylbenzenoid sulfides. Bruno H. Wojcik (to Hooker Electrochemical Co.). U. S. 2,185,007, Dec. 26. A process for the production of dibenzenoid alkyl compds., such as dibenzyl disulfide, in which 2 alkyl benzenoid groups are joined through their alkyl groups by at least one S atom, comprises adding a benzenoid alkyl halide, such as benzyl chloride, to an aq. soln. of a compd. of an alkali metal with S such as Na sulfide, in the absence of any mutual solvent for the reagents, the rate of addn. being regulated to maintain a reacting temp. without causing boiling, allowing the resulting mixt. to cool and the product to solidify, and sepg. the product from the aq. medium in the absence of any solvent. U. S. 2,185,008 relates to a generally similar process for the production of dibenzenoid polyalkyl compds. such as dixylyl polysulfide with use of a benzenoid polyalkyl halide such as xylyl chloride as an initial reactant. 4 5

Sulfonium sulfonates. Adrianus J. van Peski and Johan M. Hoeffelman (to Shell Development Co.). U. S. 2,185,654, Jan. 2. For the production of a sulfonium sulfonate, reaction is effected between an aromatic sulfonic acid such as *p*-toluenesulfonic acid, a dialkyl thio ether having a low-mol. hydrocarbon radical directly attached to the S atom, such as methyl cetyl sulfide, and an aliphatic monohydric primary alc. contg. up to 6 C atoms in the mol., such as MeOH, at a temp. of about 100–200°, in the presence of an inert solvent such as excess MeOH. 6 7

Nitriles of α-naphthyl-substituted lower aliphatic acids. John Weijlard and Wm. H. Engels (to Merck & Co.). U. S. 2,185,237, Jan. 2. For the production of a product such as α-naphthylacetonitrile, naphthalene is condensed, at a temp. of about 165–185° and in the presence of anhyd. $FeCl_3$, with a halogenated nitrile of a lower aliphatic acid, such as chloroacetonitrile.

Recovery of glutamic acid from solutions. Geza Braun (to Standard Brands Inc.). U. S. 2,186,162, Jan. 9. Pptn. of glutamic acid from solns. is effected by the addn. of an NH_4 salt such as NH_4 formate or NH_4 acetate. Cf. following abstr. 8

Glutamic acid. Geza Braun (to Standard Brands, Inc.). Brit. 508,841, July 5, 1939. Glutamic acid (I) is recovered from solns. by processes in which the I is first pptd. by means of NH_4 or Ca formate or acetate. Cf. preceding abstr. In Brit. 508,842, July 5, 1939, pure I is prepd. from crude I-HCl contg. NH_4Cl as an impurity by treating a soln. thereof with an aliphatic or aromatic amine or a N base, e. g., $NHEt_2$, $PhNH_2$, pyridine, quinoline, or with $(NH_4)_2CO_3$ or with a salt of a weak org. acid, e. g., a formate, butyrate or lactate of NH_4 or an alkali or alk.-earth metal, in such proportion as possesses a selective affinity for the combined HCl constituting a portion of the I-HCl, whereby free I is liberated and pptd., and sepg. the pptd. acid from assocd. substances, including NH_4Cl, dissolved in the resulting liquid. The pure I recovered may be treated in an aq. vehicle with an NH_4 or alkali metal hydroxide or carbonate to form a salt thereof, the soln. of salt being evapd. to a thick sirup, the salt crystd. from the sirup and dried. In Brit. 508,927, July 5, 1939, divided on 508,841, I is recovered from mother liquor remaining after an initial recovery of I from a soln. of I-HCl and contg. salt of an alk. earth metal or of NH_4 by removing such salt from the liquor by means of an alk. earth metal precipitant, e. g., H_2SO_4, $(COOH)_2$, or an agent that liberates NH_3 and then adding to the purified soln. HCl or other agent that ppts. the I either as a compd. or as free I. The liberated NH_3 may be distd. from the soln. The NH_3 may be liberated by an alk. earth metal hydroxide, the metal being subsequently pptd. The distd. NH_3 may be combined with HCOOH, the $HCOONH_4$ being used to effect pptn. of the I from a I-contg. soln. 9

Aromatic arsonic and stibonic acids Max Bockmühl and Gustav Ehrhart (to Winthrop Chemical Co.). U. S. 2,185,972, Jan. 2; Can. 387,168, Feb. 27, 1940. Various examples with details are given of the production of compds. of the general formula $RR_1NCHR_1CONR_1R_2$, where R stands for a radical of the benzene series contg. a substituent arsonic or stibonic acid radical, R_1 stands for H, alkyl or a lower hydroxyalkyl, and R_2 stands for an hydroxyalkyl having at least 2 hydroxyl groups and contg. up to 6 C atoms, the compds. being white powders readily sol. in water, sparingly sol. in alc. and charring, when heated, without melting, products obtained including, *inter alia*: *N*-chloroacetyl-*N*-methylglucamide, and phenylglycidemethylglucamidestibonic acid, 4-hydroxy-3-methylglucamidoacetaminobenzenearsonic acid, etc. The compds. are of therapeutic value.

Nitration of 1-naphthalenesulfonic acid. A. M. Volodarskiĭ and V. S. Kaliuzhnyĭ. Russ. 55,967, Oct. 31, 1939. 1-Naphthalenesulfonic acid is mononitrated in the presence of $CuSO_4$; this increases the yield of the 1,8-isomer.

Formamide. Nauchnyi Institut po Udobreniyam i Insektofungisidam (S. S. Dragunov and A. S. Shilina, inventors). Russ. 55,842, Oct. 31, 1939. NH_3 and CO are caused to react at ordinary pressure in the presence of Cr_2O_3 catalyst.

β-Phenethyl alcohol. Joseph W. Britton, Gerald H. Coleman and Bartholdt C. Hadler (to Dow Chemical Co.). U. S. 2,185,141, Dec. 26. A method of prepg. β-phenethyl alc. comprises hydrolyzing a β-haloethylbenzene with an aq. inorg. alk. agent, such as Na_2CO_3 or $Ca(OH)_2$ which when mixed with water to the extent of one chem. equiv. per kg. of water raises the pH to about 7.5-11.5.
